- B. The type of floor and wall construction. If more than one type, show each type of construction. Include any appropriate information of sealing or painting of wall surfaces.
- C. The number of men and women employed at the plant for each shift and toilet facilities available.

**VIII. CHANGES AND REVISIONS OF OFFICIAL PLANT** When changes in plant construction, facilities, and equipment are planned, the proposed changes are to be discussed with a representative of the Frontline Supervisor and revised prints submitted and approved prior to making the changes. Failure to comply with this requirement can be costly to a plant in terms of operating delays or corrections to unacceptable facility changes. Proposed changes and revisions may be submitted in draft form for review by:

- A. A completely revised sheet showing existing construction, equipment, and facilities with the proposed alterations and additions, or
- B. An overlay print drawn to the same scale as existing print covering the area to be modified or revised.

**IX. APPROVAL OF PRINTS AND PLANS** If the examination of the drawings, supplemental information and room specification show that they meet regulatory requirements, approval will be given. The set of the approved prints will be maintained by the plant submitting the prints. Plant management is to make their file of approved blueprints readily available to the egg products inspector and the Frontline Supervisor when requested. A final review and approval of the submitted drawings will be determined by the Frontline Supervisor. A final survey of the finished facility will also be conducted by the supervisor or designee followed by the communication of conformance with provisions of the approval and the regulations by the Frontline Supervisor. Approved prints of a new plant requesting inspection service, or for changes in an existing plant, does not constitute

operating approval. A final survey must be made by the Frontline Supervisor or", "DRAWING \u2013 BLUEPRINT GUIDE 7 a designee to determine if the plant construction and facilities are in accordance with the approved prints and the regulations. On new and existing plants, a written communication to that effect will then be provided to the applicant by the Frontline Supervisor.", "DRAWING \u2013 BLUEPRINT GUIDE 8 ROOM SPECIFICATION SHEET FOR BLUEPRINTS OF OFFICIAL EGG PRODUCTS PLANTS ROOM HEIGHT OF CEILING CEILING CONSTRUCTION FLOOR CONSTRUCTION WALL CONSTRUCTION Men\u2019s toilet facilities: Number of lavatories \_\_\_\_\_ Urinals \_\_\_\_\_ Stools \_\_\_\_\_ Maximum number of male employees per shift \_\_\_\_\_ Women\u2019s toilet facilities: Number of Lavatories \_\_\_\_\_ Stools \_\_\_\_\_ Maximum number of female employees per shift \_\_\_\_\_

"]}, {"file\_name": "FSIS\_GD\_2011\_0006", "title": "Examples of Nutrition Facts Panels for Ground Products", "num": "FSIS-GD-2011-0006", "id": "541d3bf328d4c7119b27b393c565962b8a1cab4d61c3f6162340a096976bc67b", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/import/Nutrition\_Panel\_Format.pdf", "type": "pdf", "n\_pages": 11, "word\_count": 1786, "text\_by\_page": ["FSIS Listeria Guideline January 2014 1 FSIS Compliance Guideline: Controlling Listeria monocytogenes in Post-lethality Exposed Ready-to-Eat Meat and Poultry Products January 2014", "FSIS Listeria Guideline January 2014 2 Purpose This compliance guideline provides specific recommendations that official establishments producing post-lethality exposed ready-to-eat (RTE) meat and poultry product may follow to meet the requirements of 9 CFR part 430, the Listeria Rule. It also provides information on sanitation, testing for Listeria monocytogenes (Lm), and prevention of cross contamination of post-lethality exposed, RTE meat and poultry products. This document replaces previous versions of the FSIS Listeria Guideline and Q&As. FSIS has revised this final version of the guideline to address comments on the draft version that was issued in September 2012. It also provides new information on holding products in response to FSIS\u2019s policy and procedures on not applying the mark of inspection pending certain test results. FSIS also revised the guidance to make clear that in addition to meeting the requirements of the Listeria Rule, establishments must meet the requirements of 9 CFR 416, Sanitation, and 9 CFR 417, HACCP Systems, as well as other applicable regulations. FSIS also revised the guideline to provide additional information on labeling RTE products and clarifications to labeling guidelines (Attachment 1.1: Resource 1). In addition, FSIS revised the guideline to provide updated information on the impact of multiple processing steps (hurdle effect) on the control of Listeria growth, as well as new information regarding controls for reworked product. The updated guideline also provides information on the pros and cons of compositing food contact surface samples at the laboratory. In addition, FSIS updated the guideline to clarify actions establishments should take in response to a Listeria spp. positive result in the product when establishments choose to sample products in addition to food contact surfaces (Section 3.6). Updated information is also included on the FSIS RTEPROD sampling program. This document provides guidance to assist establishments in meeting FSIS regulations. Guidance represents best practice recommendations by FSIS, based on the best scientific and practical considerations, and does not represent requirements that must be met. Establishments may choose to adopt different procedures than those outlined in the guideline, but they would need to support why those procedures are effective in controlling hazards from

Lm in post-lethality exposed RTE products. By using the recommendations in the guideline, establishments would not need to provide further support for their procedures. Summary of Changes Chapter 1: This chapter has been revised to provide clear, easy to follow information regarding the requirements of the Listeria Rule. Although this information has not changed significantly since the May 2006 version of the Compliance Guideline, FSIS recommends that establishments review this information to ensure that they are in compliance with the regulation. The information may be useful to new establishments that are starting production. In the revised version: "Step-by-step instructions have been provided, to assist establishments in determining whether their product is covered by the Listeria Rule. The requirements and recommendations for each control alternative are described." "FSIS Listeria Guideline January 2014 3" In addition, a glossary section has been provided with each chapter to further clarify the meaning of the terms used in the guidance and the Listeria Rule. Resource 1 (Attachment 1.2) has been updated to provide information about products that receive a full lethality that are not considered RTE. Chapter 2: This chapter provides updated technical information about establishing control alternatives under the Listeria Rule. In the revised version: "More in-depth information has been provided in Appendix 2.1 regarding validation of post-lethality treatments and antimicrobial agents. In addition, sanitation guidelines have been revised to include a description of intensified sanitation conducted in response to positive results. The reference section has been updated to provide more information about new technologies to control Listeria. New information has been provided in Appendix 2.3 on developing establishment employee training programs for implementing the Listeria Rule. Chapter 3: This chapter provides new and updated information on developing a Listeria Control Program to test for Lm or an indicator organism on food contact surfaces (FCS). In the revised version: "Updated information on routine testing for Listeria spp. under the three control alternatives is provided. Although there have been no changes to sampling frequency recommendations for Listeria spp., this revised chapter provides further guidance on meeting the recommended sampling frequencies and the number of samples to collect. Also, further clarification has been provided regarding FSIS expectations for sample collection and laboratory analysis of the samples. Finally, information has been provided on product and non-food contact testing (although not required by the Listeria Rule) to provide establishments with more information about the safety of their products and sanitary conditions in their food-processing environments. Chapter 4: This chapter provides new and updated information on developing enhanced sampling programs for Listeria in response to positive results from routine sampling. In the revised version: "A new table is provided (Table 4.1), clarifying timeframes for follow-up and intensified sampling, as well as hold and test of product. Intensified sampling is defined to provide establishments with more information on how to find and address the source of positive results. In addition, new information is provided on identifying and addressing Listeria trends." "FSIS Listeria Guideline January 2014 4" Findings from Food Safety Assessments (FSA) performed by FSIS in response to Lm positives have also been provided to increase awareness of common problems and lessons learned from FSA reviews. How to Use this Document The updated information in this revision of the Compliance Guideline should help establishments find specific information on the control of Lm, as needed. A glossary has been added at the end of each chapter to provide a better understanding of terminology found

in the text. Terms in the glossary have been bolded the first time they appear in the text. Boxes have been provided giving more information about points made in the text. Appendices have also been added to the end of each section to provide more detailed information regarding concepts introduced in the text. Q&A's have been incorporated into the document to assist establishments in finding specific information. If the desired information cannot be found within the Compliance Guide, FSIS recommends that users search Listeria Q&As in the AskFSIS database or submit questions through AskFSIS. Documenting these questions helps FSIS improve and refine present and future versions of the Compliance Guideline and associated issuances." , "FSIS Listeria Guideline January 2014 5 Table of Contents Introduction Page Chapter 1: Requirements of the Listeria Rule 1.1 Background 9 1.2 How Do I Determine whether My Product is Covered by the Listeria Rule? 11 1.3 The Listeria Rule Alternatives 12 1.4 Requirements for Establishments Under all Three Alternatives 16 1.5 Labeling 18 1.6 Glossary 18 1.7 References 19 Attachments 1.1 Control Requirements for Listeria monocytogenes 21 1.2 Chart of RTE vs. NRTE Products: Resource 1 22 Appendices 1.1 Product Types 24 1.2 Labeling 27 Chapter 2: FSIS Control Measures for Listeria 2.1 Post Lethality Treatments (PLT) 30 2.2 Antimicrobial Agents and Processes (AMAP) 32 2.3 Sanitation 37 2.4 Expected Levels of Control 38 2.5 Training 39 2.6 New Technology and New Ingredient Review 40 2.7 Glossary 41 2.8 References 41 Attachments 2.1 Post-lethality Treatments 46 2.2 Antimicrobial Agents or Processes 48 Appendices 2.1 Validation 55 2.2 Sanitation 68 2.3 Training 81 Chapter 3: Listeria Control Program: Testing for Lm or an Indicator Organism 3.1 Sampling for Lm or an Indicator Organism 85 3.2 Design of the Listeria Control Program 85 3.3 Routine Sampling Program 88 3.4 Frequency of Sampling and Explanation of this Frequency 90 3.5 Sample Collection and Laboratory Testing Methods 94 3.6 Other Routine Sampling 97 3.7 Glossary 100 3.8 References 101 Attachments 3.1 Possible Food Contact and Non-Food Contact Sites 102", "FSIS Listeria Guideline January 2014 6 Appendices 3.1 FSIS RTE Sampling Program 103 3.2 FSIS Sampling Procedure 107 3.3 Sample Collection and Laboratory Testing Methods 110 Chapter 4: Enhanced Sampling Program 4.1 Follow-up Sampling 115 4.2 Intensified Sampling 117 4.3 Hold and Test 118 4.4 Reprocessing Lm Contaminated Product 121 4.5 Determining Listeria Trends 122 4.6 Glossary 124 4.7 References 125 Appendices 4.1 Sampling Scenarios by Alternative 126 4.2 Hold and Test Scenario 129 4.3 Listeria Trends Examples 134 4.4 Findings from Food Safety Assessments (FSAs) 139 4.5 Response to Comments 142", "FSIS Listeria Guideline January 2014 7 Introduction Listeria monocytogenes (Lm) is a pathogen that can contaminate ready-to-eat (RTE) meat and poultry products and causes the disease listeriosis. Listeriosis is estimated to cause approximately 1,600 foodborne illnesses, 1,500 hospitalizations, and 260 deaths in the U.S. annually (Scallan et al., 2011). In most healthy individuals, listeriosis causes flu-like symptoms; however, in highly susceptible populations (e.g., the elderly, pregnant women, and immunocompromised individuals), listeriosis can lead to spontaneous abortion, septicemia, meningitis, and even death. Several outbreaks of listeriosis have been linked to the consumption of ready-to-eat (RTE) meat and poultry products contaminated with Lm. Lm is widely distributed in the environment; it is found in the air, soil, water, dust, and plant material, including silage. As such, Lm may enter the environment of processing plants and subsequently contaminate RTE meat or poultry products, as well as other ingredients. Lm has ample opportunity to occupy and thrive in various niches in a production facility, such as on floors, in drains, or in standing water. Without proper sanitation and

employee hygiene practices, Lm can easily cross-contaminate processing equipment, gloves or aprons of employees, and product. Lm has unique growth characteristics that can make it a formidable pathogen to control in the processing environment. Specifically, Lm has the ability to grow in cool damp environments where other pathogens may not and is capable of surviving freezing temperatures. Listeria species (Listeria spp.) also exhibit heat and salt tolerance. Lm is known to form biofilms on food contact surfaces (FCSs) and non-food contact environmental surfaces and, as a result, persists on these surfaces despite aggressive cleaning and sanitizing. Once Lm has established a niche, it may persist in the environment for long periods of time until the niche is identified and eliminated. RTE products are of particular concern for contamination with Lm because they may support the growth of the pathogen during refrigerated storage. In addition, since RTE products are often consumed without further cooking, there is a greater possibility of the occurrence of foodborne illness from these products if they become contaminated. Lethality treatments such as cooking meat and poultry products generally eliminate Lm; however, RTE products can be recontaminated by exposure to the environment after the lethality treatment during peeling, slicing, repackaging, and other processing steps. By controlling sanitation in the post-lethality processing environment or implementing interventions in their products, establishments can ensure that their RTE products do not become contaminated with Lm. In 2003, FSIS issued 9 CFR part 430, Control of Listeria monocytogenes in Post-lethality Exposed Ready-to-Eat Products (Listeria Rule).

According to the Listeria Rule, RTE products are considered adulterated if they contain Lm or come in direct contact with a FCS that is contaminated with Lm. FSIS testing has shown that levels of Lm in RTE meat and poultry products have decreased as a result of science-based regulations and industry efforts. However, the pathogen continues to contaminate RTE products at low levels, and illnesses from Lm-contaminated RTE products continue to occur. Furthermore, contaminated RTE products--both those that support the growth of Lm and those that do not--have been shown to cross contaminate other RTE foods at retail, exacerbating the risk of illness. Finally, the infectious dose is thought to be low for highly-susceptible populations. Therefore FSIS has maintained a \u201czero tolerance\u201d for the pathogen in RTE products and continues to strengthen programs and recommendations to reduce or eliminate Lm from RTE products." "FSIS Listeria Guideline January 2014 8 On December 10, 2012, FSIS issued a Federal Register notice (FRN), Not Applying the Mark of Inspection Pending Certain Test Results. The FRN announced that the Agency is changing its procedures and will withhold its determination as to whether meat and poultry products are not adulterated, and thus eligible to enter commerce, until all test results that bear on the determination have been received. The policy and procedures announced in the Federal Register became effective February 8, 2013. This guideline provides information for establishments to hold RTE products when FSIS tests product or food contact surfaces for Lm. This guideline provides information that establishments may use to meet the requirements of the Listeria Rule. It also provides \u201csafe harbors\u201d that establishments can implement to help ensure that the requirements are met." "FSIS Listeria Guideline January 2014 9 Chapter 1 FSIS Listeria Guideline: Requirements of the Listeria Rule 1.1 Background 1.2 How Do I Determine whether My Product is Covered by the Listeria Rule? 1.3 The Listeria Rule Alternatives Table 1.1: Listeria Control Alternatives 1.4 Requirements for Establishments Under all Three Alternatives 1.5 Labeling 1.6 Glossary 1.7 References Attachments 1.1 Control Requirements for Lm 1.2 Chart of

RTE vs. NRTE Products: Resource 1 Appendices 1.1 Product Types 1.2 Labeling This chapter provides information establishments can use to meet the regulatory requirements of 9 CFR part 430 (the Listeria Rule). 1.1 Background After several large outbreaks of listeriosis starting in the 1980s, FSIS and FDA worked together to implement strategies to decrease foodborne illness from Listeria monocytogenes (Lm). In September 2003, FDA and FSIS published the Quantitative Assessment of Relative Risk to Public Health from Foodborne Listeria monocytogenes Among Selected Categories of Ready-to-Eat Foods.\u201d This risk assessment indicated that deli meats and hotdogs posed the greatest per serving risk of illness and death from Lm. In May 2003, FSIS issued the \u201cFSIS Risk Assessment for Listeria monocytogenes in Deli Meats.\u201d This risk assessment indicated that the use of a combination of growth inhibitors and post-lethality interventions to control Lm in deli meats exposed to the environment after the lethality treatment has the greatest impact on lowering the risk of illness or death from Lm. The Agency used these risk assessments as resources in developing the regulations to control Lm in RTE meat and poultry products. In 2003, FSIS issued the interim final rule, Control of Listeria monocytogenes in Post-lethality Exposed Ready-to-Eat Products (the Listeria Rule). The Listeria Rule codified the regulations establishments are required to follow to produce safe RTE products. According to the Listeria Rule, Lm is a hazard that establishments producing post-lethality exposed RTE products must control. Establishments can control Lm in the product through their Hazard Analysis and Critical Control Point (HACCP) plans or prevent Lm in the post-lethality processing environment through a Sanitation Standard Operating Procedure (SOP) or other prerequisite program. According to the Listeria Rule, post-lethality exposed RTE products are considered adulterated if they contain Lm or come in direct contact with a food contact surface (FCS) that is contaminated with Lm. The Listeria Rule established three alternative methods establishments can use in controlling Lm contamination of post-lethality exposed RTE products.", "FSIS Listeria Guideline January 2014 10 \u2022 Under Alternative 1, an establishment applies a post-lethality treatment (PLT) to reduce or eliminate Lm and an antimicrobial agent or process (AMAP) to suppress or limit growth of Lm (see Chapter 2 for more information on PLTs and AMAP). \u2022 Under Alternative 2, an establishment applies either a PLT or an AMAP. \u2022 Under Alternative 3, the establishment does not apply any PLT, AMAP; instead it relies on its sanitation program to control Lm. These alternatives increase in the stringency of their control from Alternative 3 to Alternative 1 and FSIS samples establishments in Alternative 3 at a higher rate than those in Alternative 1. The Listeria Rule only applies to products that are RTE and exposed to the environment after the lethality step (post-lethality exposed). The lethality step can be defined as cooking or another process (such as fermentation or drying) that results in a product that is safe for consumption without further preparation. NOTE: Products that are considered RTE but not post-lethality exposed are not subject to the Listeria Rule but are still sampled under the RTEPROD\_RAND project code (see Appendix 3.1 for more information on FSIS RTE sampling projects).", "FSIS Listeria Guideline January 2014 11 1.2 How Do I Determine whether My Product is Covered by the Listeria Rule? Step 1. Determine whether the product is ready-to-eat (RTE). \u2022 A product is considered RTE if there is a standard of identity<sup>1</sup> defining it as fully cooked (e.g., hotdogs or barbecue) or a common or usual name that consumers understand to refer to RTE product (e.g., p\u00e2t\u00e9), or if it meets the definition in the Listeria Rule (9 CFR 430.1). \u2022 HACCP regulations require that the establishment support that its food safety system controls possible

hazards in the product, and that the establishment documents this support. For more information, see Section 1.4. \u2022 Examples of RTE products: deli products, hotdog products, whole hams, sausages, meat salads, and other products that have been treated with a lethality step. \u2022 See Attachment 1.2 for further determination if a product is RTE or not ready-to-eat (NRTE). \u2022 NRTE products are not covered by the Listeria Rule. Step 2. Determine whether the product is postlethality exposed. \u2022 If the product is RTE, determine whether the product is exposed to the environment after the lethality treatment (e.g., cooking) and before packaging. \u2022 Examples of post-lethality exposure: o Product that is exposed to the environment after the lethality step during processing, slicing, freezing, or packaging; o Product that is removed from the cooking bag at an official establishment and sliced or cut up and re-packaged; and o Product that is acidified\fermented or salt-cured or dried and smoked and then packaged. \u2022 Examples of post-lethality exposed RTE products may include: sliced roast beef, cooked ham for slicing, hotdogs, fermented sausages, cured ham, and jerky. Step 3. Determine whether the product is covered by the Listeria Rule. \u2022 If product is RTE and post-lethality exposed it is subject to the Listeria Rule. \u2022 If product is RTE but not post-lethality exposed it is not subject to the Listeria Rule. 1 Standards of identity for meat and poultry products can be found in 9 CFR Part 319. Product Considerations Note: See Appendix 1.1 for more examples. \u2022 Frozen products may be considered RTE if they do not contain safe handling instructions and they do not need to be cooked for safety (although they may be heated to increase palatability). \u2022 Cook-in-bag products that remain in the same bag until the product leaves the establishment are not considered post-lethality exposed. \u2022 Hot-filled products at 160\u00b0F (or other lethality temperatures), such as fats and lards, are considered RTE but not considered post-lethality exposed. \u2022 Soups and other products that are cooked to eliminate pathogens and hot packed in the final packaging are RTE but not post-lethality exposed. \u2022 Country cured ham (and other similar products) may be considered either RTE or NRTE, depending on how they are processed and labeled." "FSIS Listeria Guideline January 2014 12 1.3 The Listeria Rule Alternatives According to the Listeria Rule, Lm is a hazard that establishments producing post-lethality exposed RTE products must control through a HACCP plan or prevent through a Sanitation Standard Operating Procedure (SOP) or a prerequisite program (9 CFR 430.4(a)). To maintain the sanitary conditions to meet this requirement, establishments must comply with one of three alternatives (9 CFR 430.4(b)). The Listeria alternatives are designed to address post\u2013lethality contamination of Lm in RTE products. Each establishment must designate which alternative it intends to implement for a particular product. Each alternative consists of a single control method or combination of control methods which establishments must apply (see Table 1.1). Establishments may utilize one alternative for all of their products or produce product under multiple alternatives (see the section below on establishments under multiple alternatives). For more information on control measures (e.g., PLT and AMAP), see Chapter 2. Table 1.1 Listeria Control Alternatives Alternative 1 (Alt. 1) The establishment uses a post-lethality treatment (PLT) to reduce or eliminate Lm in the product and an antimicrobial agent or process (AMAP) to limit or suppress growth of Lm in the product. Alternative 2, Choice 1 (Alt. 2a) The establishment uses a PLT to reduce or eliminate Lm in the product. Alternative 2, Choice 2 (Alt. 2b) The establishment uses an AMAP to limit or suppress growth of Lm in the product. Alternative 3 (Alt. 3) The establishment relies on sanitation alone to control Lm in the processing environment and on

the product. There are separate requirements for deli meat and hotdogs under this alternative. Establishments may also change the production process to meet the requirements for a particular alternative. For example, if an establishment employs only sanitation procedures to control Lm (Alt. 3) but later implements an AMAP, it could then meet the requirements for Alt. 2. Establishments are encouraged to use AMAPs or PLTs, if possible, to reduce the risk of Lm. Further information describing the requirements and recommendations for the three alternatives is provided below. Attachment 1.1 outlines the 9 CFR 430.4 requirements for Alt. 1, 2, and 3. Alternative 1 (9 CFR 430.4(b)(1)) Alt. 1 requires the use of a PLT to reduce or eliminate Lm and an AMAP to suppress or limit the growth of the pathogen. NOTE: The following sections describe both requirements in the Listeria Rule and recommendations to meet these requirements. When the word \u201cmust\u201d is used, it refers to a requirement. When the word \u201cshould\u201d is used, it refers to a recommendation.", "FSIS Listeria Guideline January 2014 13 \u2022 The establishment must apply a PLT to control Lm in the product and must include the PLT in its HACCP plan.2 \u2022 The establishment must validate the effectiveness of the PLT in accordance with 9 CFR 417.4. \u2022 The PLT should demonstrate at least a 1-log decrease before the product is released into commerce. \u2022 The establishment must use an AMAP to control Lm in the product and must include the agent or process in the establishment\u2019s HACCP plan, Sanitation SOP, or other prerequisite program. \u2022 The establishment must document in its HACCP plan, Sanitation SOP, or other prerequisite program that the AMAP, as used, is effective in suppressing or limiting growth of Lm. The AMAP should demonstrate that no more than 2-logs of growth of Lm will occur over the shelf life of the product. \u2022 If Lm control measures are incorporated into the establishment\u2019s Sanitation SOP, the effectiveness of the measures must be evaluated in accordance with 9 CFR 416.14. If Lm control measures are addressed in a pre-requisite program other than the Sanitation SOP, the establishment must include the program and results of the program in the documentation that the establishment is required to maintain under 9 CFR 417.5. \u2022 Because Alt. 1 includes a combination of controls, the Agency does not require establishments using Alt. 1 to have a testing program for FCS. However, testing is recommended (see Table 3.1). Testing FCS in Alt. 1 could be minimal and primarily serve as a means to verify that the sanitary conditions in the establishment will not overwhelm the PLT. \u2022 As with all control alternatives, an establishment with products in Alt. 1 must maintain sanitation in the post-lethality processing environment in accordance with 9 CFR 416. An example of a product that would fall under Alt. 1 would be deli and hotdog products that receive a PLT (such as steam pasteurization after packaging) and has an AMAP (such as the addition of lactates or diacetates in the formulation). Alternative 2 (9 CFR 430.4(b)(2)) Alt. 2 requires the use of either a PLT (Alt. 2a) or an AMAP that controls the growth of Lm over the shelf life of the product (Alt. 2b). 1. Alternative 2, Choice 1 (Alt. 2a) \u2022 The establishment must apply a PLT to control Lm in the product and must include the PLT in its HACCP plan. 2 According to 9 CFR 417.", "FSIS Listeria Guideline January 2014 14 \u2022 The establishment must validate the effectiveness of the PLT in accordance with 9 CFR 417.14. \u2022 The PLT should demonstrate at least a 1-log decrease before the product is released into commerce. \u2022 As with Alt. 1, establishments in Alt. 2a are not required to test FCS; however, FSIS recommends that establishment test the surfaces on a regular basis to demonstrate that its system is in control (for more information on testing for Alt. 2, see Table 3.1). \u2022 As with all control alternatives, an establishment with

products in Alt. 2a must maintain sanitation in the post-lethality processing environment in accordance with 9 CFR 416 An example of a product in Alt. 2a is a hotdog or deli product that is treated with a postpasteurization treatment after packaging, such as a steam treatment, and DOES NOT contain antimicrobials, such as lactate and diacetate. 2. Alternative 2, Choice 2 (Alt. 2b) \u2022 The establishment must use an AMAP to control growth of Lm in the product and must include the agent or process in the establishment\u2019s HACCP plan, Sanitation SOP, or other prerequisite program. \u2022 The establishment must document in its HACCP plan, Sanitation SOP, or other prerequisite program that the AMAP, as used, is effective in suppressing or limiting growth of Lm. The AMAP should demonstrate no more than 2-logs of growth of Lm will occur over the shelf life of the product. \u2022 If Lm control measures are incorporated into the establishment\u2019s Sanitation SOP, the effectiveness of the measures must be evaluated in accordance with 9 CFR 416.4. If Lm control measures are addressed in a pre-requisite program other than the Sanitation SOP, the establishment must include the program and results of the program in the documentation that the establishment is required to maintain under 9 CFR 417.5. \u2022 Under Alt. 2b, the establishment must test FCS in the post-lethality environment to ensure that the surfaces are sanitary and free of Lm or its indicator organisms (e.g., Listeria spp.). It must also indicate testing frequency, identify the size and location of sites to be tested, explain why the testing frequency is sufficient to control Lm, and identify conditions for hold and test when an FCS is positive for Lm or an indicator organism. Recommended testing frequencies for this alternative are included in Table 3.1. \u2022 As with all alternatives, the establishment must maintain sanitation in the post-lethality environment according to 9 CFR 416. An example of products in Alt. 2b is deli and hotdog products with antimicrobial agent (AMA) such as lactates and diacetates added to the formulation, but with no PLT. Another example of a product under Alt. 2b would be a frozen RTE product.", "FSIS Listeria Guideline January 2014 15 Alternative 3: Non-deli or Hotdog Producers (9 CFR 430.4(b)(3)(i)) Under Alt. 3, the establishment does not apply a PLT to reduce or eliminate Lm or an AMAP to control the growth of Lm in the post-lethality exposed product. Instead, it relies on sanitation alone to control Lm in the product. \u2022 The establishment must control Lm in its post-lethality processing environment through the use of sanitation control measures, which may be incorporated in the establishment\u2019s HACCP plan, Sanitation SOP, or prerequisite program (Listeria Control Program). \u2022 If Lm control measures are incorporated into the establishment\u2019s Sanitation SOP, the effectiveness of the measures must be evaluated in accordance with 9 CFR 416.14. If Lm control measures are addressed in a pre-requisite program other than the Sanitation SOP, the establishment must include the program and results of the program in the documentation that the establishment is required to maintain under 9 CFR 417.5. \u2022 As with establishments in Alt. 2b, establishments in Alt. 3 must provide for testing FCS in the post-lethality processing area to ensure that surfaces are sanitary and free of Lm or its indicator organisms, indicate testing frequency, identify the size and location of sites to be tested, explain why the testing frequency is sufficient to control Lm, and identify conditions for hold and test when an FCS is positive for Lm or an indicator organism. Recommended testing frequencies are included in Table 3.1. An example of a product in Alt. 3 is refrigerated chicken nuggets that are not treated with a PLT and are not formulated using AMAs. Alternative 3: Deli or Hotdog Producers (9 CFR 430.4(b)(3)(ii)) In addition to meeting the above requirements for Alt. 3 products, there are special requirements for establishments that

produce deli or hotdog products under Alt. 3. Establishments must verify that the corrective actions taken after an initial positive test for Lm or its indicator organisms on an FCS in the post-lethality processing treatment are effective. This is achieved by performing follow-up testing for Lm or an indicator organism after the FCS positive test that includes a targeted test of the specific site on the FCS that is the most likely source of contamination and additional tests in the surrounding FCS area. If follow-up testing yields a second positive result, hold and test products that may be contaminated using a sampling method and frequency that will provide a level of statistical confidence that will ensure that lots are not adulterated. NOTE: According to the Listeria Rule, products and the processing environment under Alt. 3 are likely to be subject to more frequent verification testing by FSIS than products and the processing environment in Alt. 1 or 2. In fact, Alt. 3 products are sampled at a higher rate in the FSIS risk-based sampling code (RTEPROD\_RISK). See Appendix 3.1.","FSIS Listeria Guideline January 2014 16 An establishment in Alt. 3 that produces deli meat or hotdog products will be subject to more frequent FSIS verification testing than one that does not produce such products because deli and hotdog products were ranked as higher risks for Lm contamination in the 2003 FDA/FSIS risk assessment. Examples of deli and hotdog products in Alt. 3 include sliced turkey breast luncheon meat and packaged hotdogs that are not held frozen and not formulated using an AMA. Establishments under Multiple Alternatives FSIS recognizes that establishments may produce products under multiple alternatives. These products may be produced under multiple HACCP plans or grouped under a single HACCP plan. Products can be grouped in a single HACCP plan when the hazards, CCPs, and critical limits are essentially the same. Thus, a single HACCP plan could cover hotdogs formulated with and without antimicrobial agents (Alt. 2 and 3), provided that the HACCP plan clearly distinguishes any critical differences. If an establishment produces products using two (or three) alternative Control Programs, FSIS\u2019s sampling focus will be on product manufactured under Alternative 3, then 2a and b, then 1. 1.4

Requirements for Establishments Under all Three Alternatives According to the Listeria Rule (9 CFR 430.4(c)), establishments in all three alternatives: May use verification testing for Lm or an indicator organism (e.g., Listeria spp.) to verify the effectiveness of their sanitation procedures in the post-lethality processing environment. Sanitation measures for controlling Lm and AMAP\u2019s or PLT\u2019s may be incorporated into the establishment\u2019s HACCP plan (required for PLT\u2019s) or in its Sanitation SOP or other prerequisite program. When these control procedures are incorporated into the Sanitation SOP or other prerequisite programs, the establishment must have documentation that supports the decision in its hazard analysis that Lm is not a hazard that is reasonably likely to occur. The establishment must maintain sanitation in the post-lethality processing environment accordance with 9 CFR 416. NOTE: According to the Listeria Rule, RTE products are considered adulterated if they are contaminated with Lm or pass over a surface that is contaminated with Lm. Establishments are required to hold or to maintain control of RTE products that FSIS has tested for Lm, and RTE products that have passed over food contact surfaces that FSIS has tested for Lm. Establishments may move such products off site provided they maintain control of them (e.g., through company seals). NOTE: Deli salads and wraps are not considered deli products (according to the Listeria Rule) because they are not sliced and are also not typically used in a sandwich.","FSIS Listeria Guideline January 2014 17 If the Lm control measures are included in the HACCP plan, the establishment must validate and verify the measures in

accordance with 9 CFR 417.4. If the Lm control measures are included in the Sanitation SOP, the effectiveness of the measures must be evaluated in accordance with 9 CFR 416.14. If the Lm control measures are included in a prerequisite program other than the Sanitation SOP, the establishment must include the program and the results produced by the program in the documentation that the establishment is required to maintain under 9 CFR 417.5. The establishment must make verification results available upon request to FSIS personnel. Other Requirements In addition to meeting the requirements of the Listeria Rule, establishments must meet the requirements of 9 CFR 416, Sanitation, and 9 CFR 417, HACCP Systems. Producers of RTE products must support that they are maintaining sanitation in the processing environment according to 9 CFR 416, and preventing or controlling the food safety hazards in their product according to 9 CFR 417.2(a)(1) and documenting the support according to 9 CFR 417.5(a)(1). For RTE products, FSIS recommends that the establishment achieve lethality of pathogens (e.g., *Salmonella*) in the product, and stabilize the product to inhibit the growth of spore-forming bacteria (e.g., *C. botulinum* and *C. perfringens*). The establishment needs to be able to support that its product is RTE at the end of the process. The requirements of the Listeria Rule will only be effective as long as sanitation is maintained, and the HACCP plan is effective to control the hazards in the system. Sanitation problems can lead to Listeria harborage and cross contamination of RTE meat and poultry products (see Chapter 4 of this guideline). This cross contamination may overwhelm the effectiveness of the establishment's Listeria controls and impact its ability to support its decision that Listeria is not reasonably likely to occur in its products. For example, if an establishment has condensation dripping from the ceiling that is not adequately addressed in its sanitation program, harborage of Lm could occur in its post-lethality exposed processing environment. This contamination could spread to food contact surfaces and contaminate the product with Lm. If the establishment's post lethality treatment is designed to achieve a 1-log reduction of Lm, it may be overwhelmed by the additional contamination and no longer be sufficient to ensure the safety of the product. In that case, the establishment may no longer be able to demonstrate that its HACCP system is effective in controlling pathogens. Likewise, the establishment may find positive results from the food contact surface testing it performs as part of its sanitation SOP to meet the requirements of the Listeria Rule. These positive results may indicate that there are sanitation issues in the establishment's environment that need to be addressed to ensure the safety of the product. For example, the establishment has a hole in the wall, allowing insulation to become saturated with water, and a harborage point for Lm to form. Through an investigation, the establishment determines that the Lm from the hole in the wall could have spread to food contact surfaces, leading to the positive testing result. The establishment takes corrective actions (in accordance with 9 CFR 416.15(a)) by repairing the hole, while at the same time reassessing its Sanitation SOP (in accordance with 9 CFR 416.15(b)) to ensure that cross contamination to food contact surfaces does not occur. In "FSIS Listeria Guideline January 2014" 18 addition, because the establishment uses its Sanitation SOP to support its decision that Lm is not reasonably likely to occur on its product, it reassesses its HACCP plan (in accordance with 9 CFR 417.3(b)(4)) to ensure that its controls for Lm are effective in light of this issue. As these examples show, it is critical that establishments producing RTE products ensure that their systems are working together to control pathogens. A Listeria Control Program by itself will not be effective, unless it is used along with the sanitation

and HACCP programs to control the hazards from pathogens.

**1.5 Labeling** According to the Listeria Rule, an establishment that controls Lm by using a PLT or an AMAP may declare this fact on the label, provided that the establishment has validated the claim (9 CFR 430.4(e)). The purpose of such claims is to inform consumers about measures taken by the processor to ensure the safety of the product and enable consumers to make informed purchase decisions. Such claims are voluntary and may be of value to consumers, especially those in groups most vulnerable to foodborne illness. Processors need to document their validation of these claims, as described in Appendix 2.1. For further labeling resources, see Attachment 1.2 and Appendix 1.2. In addition, if an establishment labels the product as RTE (e.g., does not include safe handling instructions, see Attachment 1.1), it is required to process the product to render it RTE, in accordance with 9 CFR 317.2(l) and 381.125(b). To meet these requirements, the establishment's process must be validated to achieve at least a 6.5 log reduction of Salmonella for cooked beef, roast beef, and cooked corned beef products (9 CFR 318.17), a 5-log reduction for uncured meat patties (9 CFR 318.23), a 7-log reduction for cooked poultry products (9 CFR 381.150), or other equivalent lethality. FSIS will review the establishment's supporting documentation for its lethality and stabilization processes to verify that the establishment is meeting the requirements. Alternative means of achieving lethality may also be sufficient, as long as the establishment can support the effectiveness of its process. See the FSIS Salmonella Compliance Guidelines for Small and Very Small Meat and Poultry Establishments that Produce Ready-to-Eat (RTE) Products for more information.

**1.6 Glossary**

**Alternative:** A method of control for Lm adopted by an establishment to meet the requirements of the Listeria Rule.

**Antimicrobial Agent (AMA):** A substance in or added to an RTE product that has the effect of reducing or eliminating a microorganism, including a pathogen such as Lm, or that has the effect of suppressing or limiting growth of a pathogen, such as Lm, in the product throughout the shelf life of the product. Examples: potassium lactate and sodium diacetate, which limit the growth of Lm (9 CFR 430.1).

**Antimicrobial Process (AMP):** An operation, such as freezing, that is applied to an RTE product that has the effect of suppressing or limiting the growth of a microorganism, such as Lm, in the product throughout the shelf life of the product. Other examples are processes that result in a pH or water activity that suppresses or limits microbial growth (9 CFR 430.1).<sup>19</sup>

**Cook-in-bag:** Product that is cooked in an impermeable package or casing and is not exposed to the environment of the establishment after the lethality treatment.

**Deli product:** A ready-to-eat meat or poultry product that typically is sliced, either in an official establishment or after distribution from an official establishment, and typically is assembled in a sandwich for consumption (9 CFR 430.1).

**Food contact surface (FCS):** A surface in the post-lethality processing environment that comes in direct contact with RTE product (9 CFR 430.1).

**Hotdog product:** A RTE meat or poultry frank, frankfurter, or wiener, such as a product defined in 9 CFR 319.180 and 319.181 (9 CFR 430.1).

**Listeria monocytogenes (Lm):** A foodborne pathogen that can cause the disease listeriosis in humans.

**Listeriosis:** A disease caused by Lm. In most healthy individuals, listeriosis causes flu like symptoms; however in the elderly, pregnant women and their fetuses, and immunocompromised individuals, listeriosis can lead to spontaneous abortion, septicemia, meningitis, and death.

**Post-lethality Exposed Product:** Ready-to-eat product that comes into direct contact with an FCS after the lethality treatment (e.g., cooking) in a post-lethality processing environment. Examples of post-lethality exposed products:

hotdogs after the casings are removed; cooked roast beef after removing the cooking bag (9 CFR 430.1). Post-lethality Processing Environment: The area in an establishment into which product is routed after having been subjected to an initial lethality treatment. The product may be exposed in this area as a result of slicing, peeling, re-bagging, cooling semi-permeable encased product with a brine solution, or other procedures (9 CFR 430.1). Post-lethality Treatment (PLT): A lethality treatment that is applied or is effective after postlethality exposure. It is applied to the final product or sealed package of product in order to reduce or eliminate the level of pathogens resulting from contamination from post-lethality exposure (9 CFR 430.1).

Ready-to-eat (RTE): A meat or poultry product that is in a form that is edible without additional preparation to achieve food safety and may receive additional preparation for palatability or aesthetic, epicurean, gastronomic, or culinary purposes. RTE product is not required to bear safe-handling instruction (as required for non RTE products by 9 CFR 317.2(1) and 381.125(b)) or other labeling that directs that the product must be cooked or otherwise treated for safety and can include frozen meat or poultry products (9 CFR 430.1). 1.7 References FDA and FSIS.

May include cuts of meat and poultry, cured pork products, and NRTE sausage. Or A meat\poultry product (in whole or in part) which has received an adequate lethality treatment for Salmonella, that is not defined by a standard of identity or a common or usual name that consumers understand to refer to RTE product and does not meet the definition of RTE\* in 9 CFR 430.1. May include NRTE ham, casseroles, and other meat or poultry dishes. Not ready-to-eat \u2022 Raw Product Ground Raw Product Not Ground \u2022 Not Heat Treated Shelf Stable \u2022 Heat Treated \u2013 shelf stable \u2022 Heat Treated but not Fully Cooked Not Shelf Stable Products with secondary inhibitors Not Shelf Stable Product must be labeled with statements such as keep refrigerated, keep frozen, or refrigerate leftovers, if not shelf stable. Use of Safe Handling Instruction (SHI) labeling required. \u2022 Use of SHI labeling (Some establishments may have a CCP for SHI labeling application). If it is not obvious that the product is raw and needs to be cooked: \u2022 Features on labeling are conspicuous so that intended user is fully aware that product must be cooked for safety. This is best conveyed through the product name (e.g., \u201cCook and Serve\u201d) but may also be conveyed by the use of an asterisk on the product name that is associated with a statement on the principle display panel or by a burst stating such things as \u201cneeds to be fully cooked,\u201d \u201csee cooking instructions,\u201d or \u201ccook before eating.\u201d \u2022 Validation that: a. Cooking and preparation instructions on the product are sufficient to destroy pathogens. b. Instructions are realistic for the intended consumer. \*A meat or poultry product that is edible without any additional preparation to achieve food safety.", "FSIS Listeria Guideline January 2014 23 A product containing a meat\poultry component that is RTE in combination with nonmeat\poultry components that needs to receive a lethality treatment by the intended user. The final product does not meet the definition of RTE in 9 CFR 430 because it contains raw components. May include meals, dinners, and frozen entrees. Not ready-to-eat \u2022 Heat Treated but not Fully Cooked Not Shelf Stable Product must be labeled with statements such as keep refrigerated or frozen. Use of SHI labeling is recommended. NOTE: SHI are not required because the meat or poultry component is RTE. However, FSIS recommends SHI for these products because raw nonmeat ingredients are added. \u2022 Validation that: a. The meat\poultry component received an adequate lethality treatment for pathogens (see Section 1.4). b. Cooking and preparation instructions on the product are sufficient to destroy pathogens. c. Instructions are realistic for the intended consumer. \u2022 Features on labeling are conspicuous so that intended user is fully aware that product must be cooked for safety (e.g., \u201cCook and Serve\u201d). May also be conveyed by the use of an asterisk on the product name that is associated with a statement on the principle display panel, or by a burst stating such things as \u201cneeds to be fully cooked\u201d, \u201csee cooking

instructions\ufe0f, or \ufe0fcook before eating.\ufe0f If necessary, hazard analysis should address whether instructions on the label are needed related to cross-contamination (e.g., avoid contact of contents) and prevention of pathogenic growth (e.g., promptly refrigerate leftovers). NOTE: Inspection program personnel are to collect samples as RTE if the establishment does not follow the guidance above. A meat\poultry product that has received an adequate lethality treatment for Salmonella that may or may not be defined by a standard of identity or a common or usual name that consumers understand to refer to RTE product, and meets the definition of RTE in 9 CFR 430. RTE products that are postlethality exposed must meet the requirements of 9 CFR part 430. May include hotdogs, deli meat, and RTE sausages.

Ready -to-eat \ufe0f Not Heat Treated Shelf Stable \ufe0f Heat Treated Shelf Stable \ufe0f Fully Cooked Not Shelf Stable \ufe0f Products with secondary inhibitors Not Shelf Stable If the product is not shelf stable, labeling such as keep refrigerated or frozen is required. SHI are not required and should not be used because they could be misleading to consumers. \ufe0f Validation that the meat or poultry component received an adequate lethality treatment for pathogens (e.g., a 5-log reduction of Salmonella). \ufe0f The establishment meets the requirements of 9 CFR 430 if the product is post-lethality exposed. \ufe0f Heating (not cooking) instructions may be included. \ufe0f Statements on the principle display panel may indicate that the product is RTE and does not have to be cooked for safety (e.g., \ufe0f fully cooked,\ufe0f \ufe0fheat and serve\ufe0f)." , "FSIS Listeria Guideline January 2014 24

Appendix 1.1: Product Types Overview of products covered under Listeria Rule Establishments that produce post-lethality exposed RTE meat and poultry products are covered by the Listeria Rule. Accordingly, the establishment should determine the alternative(s) to which it will adhere to in its processes to control L<sub>m</sub> during the post-lethality exposure. The following product types, if post-lethality exposed, would fall under the Listeria Rule. The classification of deli products and hotdog products, salad\spread\p\ufe0e2t\ufe0e9 products, cook-in bag products, frozen, and hot-packed products will be described.

I. Deli and Hotdog Products As defined in 9 CFR 430.1, a deli product is \ufe01ca ready-to-eat meat or poultry product that typically is sliced, either in an official establishment or after distribution from an official establishment, and typically is assembled in a sandwich for consumption.\ufe01d RTE hotdog (or hot dog) products are defined in 9 CFR 430.1 as \ufe01ca ready-to-eat meat or poultry frank, frankfurter, or wiener, such as a product defined in 9 CFR 319.180 and 319.181.\ufe01d Cooked sausages (e.g., bratwurst), as defined in 9 CFR 319.140, would be considered RTE, but would not be considered to be deli or hotdog products. Post-lethality exposed whole meat and poultry products (e.g., deli loaves) that are destined for slicing at a retail establishment are also considered to be deli products. NOTE: Deli loaves that are non post-lethality exposed (e.g., cook-in bag) that are sliced at retail are not considered to be deli products because they are not covered by the Listeria Rule, see Section III below. Like all RTE products exposed to the processing environment, deli and hotdog products that are exposed to the post-processing environment are subject to the Listeria Rule. If the RTE product is not exposed to the post-processing environment, it is not subject to the Rule. Depending on the method that an establishment chooses to control L<sub>m</sub> contamination in its processing, deli and hotdog products may be in Alt. 1, 2, or 3. NOTE: The Listeria Rule definition of deli products applies only to deli products produced official establishments. Deli products produced at retail can include deli salads, meats, and other products. Deli and hotdog products that receive a PLT and AMAP fall

under Alt. 1. An example is a hotdog that includes lactates or diacetates in the formulation and is steam pasteurized after repackaging. Deli and hotdog products with antimicrobial agents such as lactates or diacetates added in the formulation, but with no post-process lethality treatment, would fall under Alt. 2b. An example of an Alt. 2a product is a hotdog product that received only a PLT, such as being Question: A scrapple product receives a full lethality treatment at the establishment. Is the product required to be RTE? Answer: No. Unless the product has a standard of identity requiring it to be RTE (9 CFR 319 and 9 CFR 381), it can be considered to be NRTE. NRTE products are required to bear safe handling instructions, and should be labeled with validated cooking instructions. In addition, if the product is NRTE but appears to be RTE, it should be labeled conspicuously so that intended user is fully aware that product must be cooked for safety (see Attachment 1.2). The establishment's HACCP plan and intended use statement should also be consistent with a NRTE product (see Appendix 1.2 part II below).", "FSIS Listeria Guideline January 2014 25 packaged in casings with an antimicrobial agent that reduces the level of Lm. If an establishment does not use a PLT or an AMAP in the processing of deli and hotdog products, these products would fall under Alt. 3. II. Salad\Spread\P\u00e2t\u00e9 Products Salads\spreads\p\u00e2t\u00e9s are also RTE post-lethality exposed, so they are covered by the Listeria Rule. RTE meats that are used in salads receive additional handling after they are removed from their packages and are mixed with other ingredients, thus exposing them to crosscontamination. An establishment producing salads with the meat and poultry components that receive a PLT or antimicrobial agent needs to have supporting documentation showing that the antimicrobial action is sufficient to control Lm in all the salad ingredients if it chooses to have its product in Alt. 1 or 2. A salad\spread\p\u00e2t\u00e9 product with a final pH below 4.39 in all ingredients of the salad (e.g., due to the salad dressing or other ingredients added) would fall under Alt. 2, if an antimicrobial agent is used. Salads\spreads\p\u00e2t\u00e9s are not considered deli products under the Listeria Rule because they are not typically sliced. III. Cook-in Bag products A cook-in-bag product such as a cooked ham or poultry roll that leaves the federal establishment intact in its cooking bag is not covered by the Listeria Rule because it is not postlethality exposed. However, once the product is removed from its package, it should be handled using good sanitary controls so that it does not become contaminated with Lm. IV. Frozen Products Frozen products are covered under the Listeria Rule if they are considered RTE and postlethality exposed. Although freezing controls the growth of Lm, the organism can still survive the freezing process. Frozen products generally fall under Alt. 2b (use of an antimicrobial agent or process to control Lm). The Listeria Rule defines an antimicrobial process as an operation, such as freezing, that is effective throughout the shelf life of the product. Therefore, to meet the definition of an antimicrobial process, and to qualify for Alt. 2b, the product would need to remain frozen throughout its shelf life. If the product is meant to be thawed and held refrigerated either at the establishment or at a retailer, the product would be considered Alt. 3. An example of a frozen product would be RTE sliced chicken strips that are frozen at the establishment and held frozen until prior to consumption. They may be heated by the consumer for palatability prior to eating. V. Hot-packed Products: Edible Oils and Fats, Lard, and Soups Edible oils and fats resulting from a rendering process that processes them to a temperature of 180\u00ba F and maintains them at 160\u00ba F are considered RTE. Rendering is intended to make this meat food product a ready-to-use ingredient in the

preparation of other foods, e.g., edible tallow and lard used as shortening. They do not require additional lethality treatment before being consumed. If these products are hot filled at a lethality temperature (e.g., Appendix A Compliance Guidelines For Meeting Lethality Performance Standards For Certain Meat And Poultry Products) and packaged, they are not considered post-lethality exposed and therefore are not covered by the Rule. However, these products would be considered RTE and not covered by the Listeria Rule if the process calls for partial rendering of the animal fat for tallow or lard and then further processing or finishing rendering in another plant.","FSIS Listeria Guideline January 2014 26 Soups and other products that are cooked to eliminate pathogens and hot-packed in the final packaging material are RTE, but are not considered post-lethality exposed. Therefore, the Listeria Rule does not apply. VI. Dehydrated Products Dehydrated products are considered to be low risk products, because they do not support Listeria growth (as long as the water activity is below 0.92). However they may be considered RTE and post-lethality exposed, depending on their intended use. Therefore, they may be sampled under the RTEPROD\_RAND and RTEPROD\_RISK project codes. Question: Are lard products covered under the Listeria Rule? Answer: It depends. Lard products that are made from a rendering process are considered to be RTE. If they are hot-filled at a lethality temperature according to Appendix A or other scientific support, they would not be considered post-lethality exposed and would not be subject to the Listeria Rule. If they are filled at lower temperatures, then the product is considered post-lethality exposed, and subject to the Listeria Rule.","FSIS Listeria Guideline January 2014 27 Appendix 1.2: Labeling I. Post-lethality Treatments (PLT) and Antimicrobial Agents or Processes (AMAP) According to the Listeria Rule, an establishment that controls L<sub>m</sub> by using a PLT or an AMAP may declare this fact on the label, provided that the establishment has validated the claim (9 CFR 430.4(e)). The purpose of such claims is to inform consumers about measures taken by the processor to ensure the safety of the product and enable consumers to make informed purchase decisions. Such claims are voluntary and may be of value to consumers, especially those in groups most vulnerable to foodborne illness. Processors need to document their validation of these claims as described in Appendix 2.1. An example of a statement that can be made is: \u201cPotassium lactate added to prevent the growth of Listeria monocytogenes.\u201d All labeling claims and label changes to add such claims must be submitted for evaluation and approval to the FSIS Labeling and Program Delivery Division. In addition, antimicrobial agents that are added to RTE products, either to the formulation or to the finished RTE product, and those that are included in the primary packaging material of RTE products must to be listed in the ingredients statement of the product. An establishment does not need to submit a label to the Agency for evaluation and approval when it adds an antimicrobial agent (e.g., sodium diacetate) to a product formulation that is approved or listed by FDA and FSIS as safe and suitable, provided that the label can be approved in accordance with the generic labeling regulations in 9 CFR 317.5 and 381.133, (i.e., the product must have a standard of identity in Title 9 of the Code of Federal Regulations (CFR) or the Food Standards and Labeling Policy Book and the labeling must not bear special claims, guarantees, or foreign language). All ingredients including antimicrobial agents require declaration on the label. Establishments may submit for temporary approval to use existing stocks of labels with revised formulations (up to six months) in order to update and produce new labels. Approval of Labels Bearing Claims As with all claims on labels, if there is a labeling claim about the use of antimicrobial agents or lethality treatments, the labels must be

submitted to the Agency for evaluation and approval before use. Documents for validation of the effectiveness of the PLT or antimicrobial agent must be included with the label application. An establishment cannot put labeling claims of enhanced protection on RTE products that are not post-lethality exposed, such as cook-in-bag that are opened only by the consumer, because these are not covered by the Listeria Rule. Special Considerations for Antimicrobial Agents in Commminuted Beef Products The standard of identity for ground beef, chopped beef, and their cooked versions does not provide for the addition of ingredients, with the exception of non-fluid condimental seasonings, e.g., salt and pepper. Therefore, these products cannot be formulated with or treated with antimicrobial agents that are classified as having a lasting technical effect, e.g., sodium lactate and sodium diacetate, unless these products are descriptively labeled to reflect the use of the antimicrobial agents. For example, if sodium lactate is added, the product name on the label should be "Ground Beef with Sodium Lactate". However, for beef patties, which are standardized products, the regulations permit the addition of ingredients such as antimicrobial agents. Therefore, comminuted beef products formulated with antimicrobial agents and other approved or listed safe and suitable food ingredients can be labeled as "beef patties" and can be generically approved if the labeling does not bear any", "FSIS Listeria Guideline January 2014 28 special claims, guarantees, or foreign language. The labeling for other products with standards of identity that permit the addition of antimicrobial agents (e.g., luncheon meats, hotdogs, cooked whole muscle cuts (such as roast beef)) may be approved in accordance with the regulations on generic label approval to reflect the addition of new, approved safe and suitable antimicrobial agents on labeling. The addition applies provided that no special claims, guarantees, or foreign language appear on such labels, per the generic labeling regulations.

II. Differentiating Products as RTE or Not RTE (NRTE)

Some products are expected to be lethality treated and RTE as shipped as part of their common or usual name that consumers understand to refer to RTE product, e.g., pâté. Other products are defined by a standard of identity as RTE, that is, cooked, e.g., hotdogs. Some products are RTE based on labeling features, including Nutrition Facts, which declare nutrients in a product on a ready-to-serve or ready-to-eat basis. When these factors do not prevail, manufacturers may decide whether to classify products as RTE or NRTE products. However, care should be taken to ensure that it is clear whether the product is RTE or NRTE (see Attachment 1.2). The following should be taken into account when differentiating RTE from NRTE product:

- (1) Decide on the HACCP category that best fits the product based on the processing operations that are involved. The HACCP categories most often used for RTE products include fully cooked/not shelf stable, not heat treated shelf stable, heat treated shelf stable, and product with secondary inhibitors not shelf stable. In the situation where a product has been produced as an RTE product and it is not a product that is defined by a common or usual name that consumers understand to refer to RTE product (e.g., pepperoni) or standard of identity (e.g., hotdog) as a lethality-treated (e.g., cooked/fermented/dried) product, the manufacturer can decide whether the product is RTE or NRTE based on HACCP category. The establishment would need to ensure that documentation exists to support the HACCP category selected by the establishment for the product and that the appropriate category is reflected in the HACCP plan and labeling records. The establishment's hazard analysis and intended use of the product should also be consistent with a RTE or NRTE product.
- (2) Generate data that validate the cooking instructions

that appear on the labeling of NRTE products (and include in all the alternative methods of cooking the temperature that the product must reach, i.e., 160°F) to ensure that consumers provide the lethality step. When the product has historically been viewed by the consumers as a RTE product, it is especially important for the establishment to make the distinction between the RTE product and the NRTE product. In addition, the cooking instructions should not be the same "heating" instructions that may be used on the labeling for RTE products. Heating instructions for RTE products should not use the word "cooking," and should not include end temperatures (e.g. 160 °F), because it could be misleading to consumers. NOTE: It is FSIS's expectation that products in the fully cooked not shelf stable category will be considered RTE." "FSIS Listeria Guideline January 2014 29 Cooking instructions for NRTE products should include the internal temperature the product is expected to reach (e.g., 160°F), and the method of cooking (e.g., oven time and temperature) so that the product is safe for consumption by the consumer. NOTE: Specific cooking instructions are not required for NRTE products, except the instruction to cook thoroughly, included as part of safe handling instructions (SHI). However, FSIS recommends that establishments provide validated cooking instructions on labels of products that are NRTE but appear to be RTE. In addition, if the establishment chooses to label a NRTE product with cooking instructions, it should validate the instructions; otherwise, they may not provide meaningful information to consumers on how to cook the product. (3) Assess the label to ensure that it adequately reflects the features that are necessary on the principal display panel to convey that the product is a ready-to-cook product, e.g., "cook and serve," "cook and eat," "cook thoroughly," as well as safe handling instructions. It would not be appropriate to label raw products using terms such as "cooked," or broiled. FSIS regulations require SHI if the meat or poultry component is NRTE and the product is not labeled for further processing. In comparison, if the meat or poultry component is RTE, but another non-meat or poultry component requires cooking for safety, the display of safe handling instructions is not required, but highly recommended. In addition, the basis for the Nutrition Facts declarations, e.g., serving size, must be on a ready-to-cook basis, not on a ready-to-serve basis (the company has to establish a ready-to-cook basis for serving size if the regulations do not provide one). The reference amount customarily consumed (RACC) for ready-to-cook and ready-to-serve meat and poultry products are found in 9 CFR 317.312 and 381.412, respectively. Nutrition labeling is not changed by this rule, but the serving size will be affected, depending on whether the product is classified as RTE or NRTE. (4) Consider whether the label for the product can be approved consistent with the regulations on generic label approval (i.e., it is a label for a standardized product that bears no claims, special statements, guarantees, or foreign language). Such labels would not need to be sent to the Agency to be evaluated and approved prior to use. If a meat or poultry product that is processed to a time/temperature that traditionally is considered to attain a full cook, but the intended use of the product is such that the product is intended to receive a lethality treatment by the consumer, the product does not have to be labeled as RTE unless the product is defined by a standard of identity as an RTE product (e.g., hotdogs, franks, and pork with barbecue sauce). Such product may be identified as an NRTE product, provided that the labeling and validated cooking instructions (SHI) are adequate to discern that the product must be cooked for safety by the purchaser. An example of such product is a cooked,

thick-sliced, center-cut ham slice on which the labeling indicates that the product is ready-to-cook and for safety the product must be cooked to attain a minimum temperature. On the other hand, a thin sliced ham product in case-ready packaging may state that the product is RTE without additional cooking and, as such, should not be labeled with cooking instructions. Both products may have been heat treated in the same manner, but the establishment would only have control for Lm in the RTE product." , "FSIS Listeria Guideline January 2014 30 Chapter 2 FSIS Listeria Guideline: FSIS Control Measures for Listeria 2.1 Post Lethality Treatments (PLT) 2.2 Antimicrobial Agents and Processes (AMAP) Table 2.1: Growth Limits for Lm 2.3 Sanitation 2.4 Expected Levels of Control Table 2.2: Expected Control Levels for Post-lethality Treatments and Antimicrobial Agents or Processes under Alternatives 1 & 2 2.5 Training 2.6 New Technology and New Ingredient Review 2.7 Glossary 2.8 References Attachments 2.1 Post-lethality Treatments 2.2 Antimicrobial Agents or Processes Appendices 2.1 Validation 2.2 Sanitation 2.3 Training This chapter provides technical information about control measures that are used to meet the requirements for the three alternatives and provides examples establishments can use to apply these control measures to their particular product. 2.1 Post-lethality Treatments (PLT) According to the Listeria Rule, post-lethality treatments (PLT) are treatments that are designed to reduce or eliminate levels of Lm contamination on RTE products. Establishments may choose to use PLT to meet the requirements of Alt. 1 (use of a PLT and antimicrobial agent or antimicrobial process (AMAP) or Alt. 2a (use of a PLT alone). According to the Listeria Rule, establishments that use PLTs must include the treatment as a CCP in their HACCP plan and validate the effectiveness of the PLT. It is FSIS\u2019s expectation that PLTs will be designed to achieve at least a 1-log lethality of Lm before the product leaves the establishment. The PLT must be validated according to 9 CFR 417.4 and 430.4 as being effective in eliminating or reducing Lm. The establishment must also verify the effectiveness of the PLT and other control measures and make these results available upon request to FSIS personnel (9 CFR 430.4(c)(7)). Expected levels of control for PLTs and AMAPs are provided in Table 2.1. 3 Ultraviolet treatment can be used either as a post-lethality treatment or antimicrobial agent or process depending on whether it eliminates, reduces, or suppresses growth of Lm. Examples of Post-lethality Treatments (PLT) PLT for Lm may include: \u2022 Steam pasteurization, \u2022 Hot water pasteurization, \u2022 Radiant heating, \u2022 High pressure processing (HPP), \u2022 Ultraviolet (UV) Treatment, \u2022 Infrared Treatment, \u2022 Drying (Low water activity) (see example 1), and \u2022 Other validated processes.", "FSIS Listeria Guideline January 2014 31 See the section on validation and verification of PLTs below and Attachment 2.1 for more information. PLTs could be effective in any post-lethality exposed RTE product, provided a study is performed demonstrating its effectiveness in the product. PLTs can be applied as: 1) Pre-packaging treatments, e.g., infrared technology (see Example 2) 2) Post-packaging treatments, e.g., \u2022 Hot water pasteurization, \u2022 Steam pasteurization, and \u2022 High pressure processing (HPP). Some of the published studies on post-lethality treatments are reviewed in Attachment 2.1. Establishments should refer to the details of these studies if they want to use the intervention methods in their processing operations. The Compliance Guideline will be updated to include studies or other methods as they become available. For more information on using published studies or other methods of validating PLTs, see the validation of PLTs section below and Appendix 2.1. Example 1: Drying (low water activity (Aw)) as an AMAP and PLT Drying is a means to kill Lm and help make a product \u201cshelf stable\u201d. Low water

activity ( $A_w$ ) limits the amount of water available to pathogens such as Lm, which will not allow them to grow. An  $A_w$  less than or equal to 0.92 will not support the growth of Lm, and an  $A_w$  of 0.85 or less (the  $A_w$  for achieving shelf stability) can sometimes even reduce Lm numbers. FSIS will consider an  $A_w$  of 0.85 at the time the product is packed to be a post-lethality treatment and an antimicrobial treatment if the establishment provides supporting documentation that Lm is reduced by at least 1-log before the product leaves the establishment and that no more than 2logs growth of Lm occurs over the shelf life of the product. See Table 2.1 for growth limits of Lm.

**Example 2: Pre-packaging Treatment (e.g., infrared technology)** as a Post-lethality Treatment A pre-packaging treatment such as infrared technology can be used as a PLT as long as it is validated to eliminate or reduce the level of Lm by at least 1 log. Infrared technologies work by heating water inside microorganisms, causing cell death. However, if there is separation between the treatment and packaging, there is a possibility that the product could be come re-contaminated after the infrared treatment. Therefore, sufficient conditions must be met to ensure a hygienic environment after the infrared treatment step to preclude re-contamination, or the post-lethality treatment would not likely be considered effective by FSIS.

Some establishments may place the packaging machine right after the radiant heat treatment to NOTE: Some AMAs or AMPs may also act as a PLT if they reduce or eliminate the pathogen and control its growth over the shelf life of the product. An example of an AMP that also acts as a PLT is a process such as drying or fermenting, which renders an RTE product shelf stable (see Example 1 below).", "FSIS Listeria Guideline January 2014 32 reduce or eliminate product exposure. If the infrared technology or other similar technology (e.g., HPP) is validated to achieve at least a 5-log reduction of Lm and other pathogens of concern (e.g., E. coli O157:H7 and Salmonella), the process would be considered to achieve full lethality and the product would not be considered to be post-lethality exposed. Sending Product to another Establishment for a PLT Establishments that produce post-lethality exposed products may send the product to another federally-inspected establishment for PLT. If the product will not be distributed into commerce until after the PLT is applied, it should be labeled \u201cfor further processing\u201d or remain under the establishment\u2019s control. The PLT should also be considered as part of the primary establishment\u2019s HACCP program, even if it is applied at a secondary establishment. Known or suspect Lm-positive product may be treated at the establishment or shipped to another establishment for PLT or other reprocessing (see Section 4.4). If a PLT is used to reprocess Lm-positive product, the process should be validated to achieve at least a 5-log reduction of Lm or an indicator organism. If the product is shipped to another establishment for reprocessing, the product should be labeled \u201cfor further processing\u201d or remain under establishment control until the PLT is applied to the product.

**Validation of PLTs** As previously stated, the PLT must be validated to reduce or eliminate Lm from the product (9 CFR 430.4(b)(1)(ii)). The validation should demonstrate at least a 1-log reduction of Lm before the product leaves the establishment (unless the PLT is being used to treat contaminated product. See above). Establishments may use published peer-reviewed papers, challenge studies, or in-house studies to validate the effectiveness of PLTs. Published research studies may be used as a reference for validation provided the critical parameters used in the study (e.g., product type or size, the type of equipment, time, temperature, pressure and other variables) match the product or process used by the establishment. In the absence of published peer-reviewed papers, unpublished studies may be

used as reference documents, provided there is supporting documentation that the data and analysis of results demonstrate that the specific level of application on specified products or range of products is effective to produce a safe product (e.g., results in at least a 1-log decrease). FSIS expects the establishment's HACCP documentation to demonstrate that the post-lethality treatment is adequate to eliminate or reduce L<sub>m</sub> by at least 1-log. In cases of pre-packaging PLT that is applied to the finished product close to the packaging step (e.g., infrared treatment), the establishment must be able to demonstrate how the level of contamination that may occur between the treatment and the packaging is eliminated. For more information on validation of PLTs and AMAPs, see Appendix 2.1. 2.2 Antimicrobial Agents and Processes (AMAPs) According to the Listeria Rule, AMAPs must suppress or limit the growth of L<sub>m</sub> throughout the shelf-life of the product. Antimicrobial agents (AMAs) can include lactates and diacetates added in the formulation of the product and growth inhibitors added in the immediate packaging material. AMAPs must be included in the establishment's HACCP plan, Sanitation SOP, or prerequisite program and the establishment must validate that the AMA P is effective as used. It is FSIS' expectation that AMAPs are designed to allow no more than 2-logs of growth of L<sub>m</sub> over the shelf-life of the product. If the AMAP is included in the FSIS Listeria Guideline January 2014 33 the establishment's HACCP plan, the establishment must validate and verify its effectiveness in accordance with 9 CFR 417.4. If the AMAP is included in the establishment's Sanitation SOP, the effectiveness of the measures must be evaluated in accordance with 9 CFR 416.14. If the AMAP is included in a prerequisite program other than a Sanitation SOP, the establishment must ensure that the program is effective and does not cause the hazard analysis or the HACCP plan to be inadequate. The establishment must include the program and the results produced by the program in the documentation that it maintains as required in 9 CFR 417.5(a). Expectations for the efficacy of AMAPs are provided in Table 2.2. For further information on validation of AMAPs, see Appendix 2.1. 1. Antimicrobial Agents (AMAs) AMAs are defined as substances added to RTE products that have the effect of suppressing or limiting growth of L<sub>m</sub> in the product throughout the shelf life of the product (9 CFR 430.1). AMAs should allow no more than 2-logs of growth over the shelf life of the product. Examples of AMAs include: potassium lactate and sodium diacetate. Growth inhibition achieved by adding antimicrobials to product formulation depends on a variety of factors, such as: 1) The level of antimicrobial agent added, 2) pH of the product, 3) Moisture level of the product, 4) Product formulation, and 5) Whether the agent was added during formulation or to the finished product. Some published studies on AMAs are reviewed in Attachment 2.2. If establishments want to use such studies as part of their validation or support, they would need to identify all of the critical operation parameters in the study and apply them to their process. See the section below on documenting the effectiveness of AMAPs and Appendix 2.1 for more information. According to the Listeria Rule, the AMAPs must be effective throughout the shelf life of the product (9 CFR 430.1). The shelf life of the product is defined as the amount of time the product can be stored under specified conditions and still remain safe with acceptable quality. Guidance can be found in the following National Advisory Committee for Microbiological Criteria for Foods (NACMCF) report: Considerations for Establishing Safety-based Consume-by Date Labels for Refrigerated Ready-to-eat Foods. Question: Can modified atmosphere packaging (M.A.P.) be used as an AMP? Answer: M.A.P. can be used as an AMP if the establishment has documentation that it

suppresses growth of Lm and other pathogens and their toxins or toxic metabolites throughout the product's refrigerated shelf life Question: Could curing (156 ppm added nitrite) be considered an AMA? Answer: Sodium nitrite is primarily used to inhibit Clostridium botulinum growth and toxin production in cured meats. Studies have shown an inhibitory effect of nitrite, salt, and vacuum packaging on Lm growth in fish. The establishment would have to provide documentation on the inhibitory effect of nitrite on Lm in meat and poultry and indicate what other factors, such as salt concentration, are critical for the inhibitory effect." "FSIS Listeria Guideline January 2014 34 AMAs can be added to the product during formulation, to the finished product, or to the packaging material. FSIS does not require a specific concentration of inhibitor to qualify as an antimicrobial agent. However, AMAs must be generally recognized as safe (GRAS) by the Food and Drug Administration (FDA) and also must have been found to be safe and suitable by FSIS. Approved antimicrobials for processed meat and poultry products can be found in 9 CFR 424.21 and FSIS Directive 7120.1. The addition of antimicrobials in the formulation must be included in the ingredient statement of the label (see Section 1.5). If an AMA is added to the surface of the product, it should be added as close to the final packaging step as possible to ensure the efficacy of the treatment. For example, if an AMA is applied to the surface of the product and the product is sliced, the AMA would no longer be valid as an AMA unless the sliced surface is also treated. An establishment may also use AMAs that inhibit Lm on equipment and FCSs. Using these inhibiting agents on equipment and FCSs can be considered as part of the sanitation program. The use of AMAs on the equipment alone, however, would not qualify the product for Alt. 1 or 2. The establishment would have to add the AMA directly to the product to meet the requirements for either of the alternatives. Hurdle Concept Some AMAPs may have increased effectiveness in controlling Lm growth when added in combination with other AMAPs. This synergistic effect is commonly referred to as the hurdle concept. RTE products with added salt, nitrites, and other additives achieve a water activity, pH, or moisture-protein-ratio that will reduce the level of Lm and other pathogens during processing, and continue to inhibit the growth of the pathogens during the refrigerated shelf-life. The added salts and nitrites work together to create hurdles to pathogen growth. These products may not be shelfstable because they need to be refrigerated during their shelf-life, but because of the combination of water activity and pH attained during the initial lethality treatment, these products may not support the growth of Lm during its refrigerated shelf-life. Example 1: Lactates and Diacetates as AMAs Lactates and diacetates are antimicrobials that can be added to the formulation of RTE meat and poultry products. These compounds are organic acids that serve to reduce the Aw and pH of the product. FSIS increased the permissible levels of sodium diacetate as a flavor enhancer and as an inhibitor of pathogen growth to 0.25 % (65 FR 3121-3123/2000). The Rule also permits the use of sodium lactate and potassium lactate in fully cooked meat, meat-food products, poultry, and poultry-food products, except for infant foods and formulas, at levels of up to 4.8 % of total product formulation, for the purpose of inhibiting the growth of certain pathogens. These include lactates and diacetates added in the formulation and growth Question: If an AMA is applied to a product at one establishment, and the product is sent to a second establishment for further processing, can the second establishment claim Alt. 2? Answer: Yes. The second establishment can claim Alt. 2, as long as it can demonstrate that the processing and sanitary conditions at the second establishment do not impact the effectiveness of the AMA or AMP over the shelf life of the product. To

demonstrate its effectiveness, the second establishment would need to obtain documentation from the first establishment regarding levels of the AMA or AMP and demonstrate that the further processing applied to the product does not impact the effectiveness of the AMA or AMP. The second establishment would also need to demonstrate that levels of Lm in its postlethality processing environment would not overwhelm the effectiveness of the AMA or AMP.", "FSIS Listeria Guideline January 2014 35 inhibitors in the immediate packaging material. Approved antimicrobials for processed meat and poultry products can be found in 9 CFR 424.21 and in FSIS Directive 7120.1. The addition of antimicrobials in the formulation must be included in the ingredient statement of the label. To meet the definition in the Listeria Rule, an AMA would need to be effective over the shelf life of the product (therefore, it can not be considered a processing aid), and should allow no more than 2 logs outgrowth of Lm. Example 2: Vinegar as an AMA Acidulants or added vinegars can be considered as AMAs, as long as the pH of the product is below 4.39, or the establishment can provide other supporting documentation demonstrating the effectiveness of the process. Vinegar serves to control pathogen growth by decreasing the pH of the product. However, Lm and other pathogens may still survive in a vinegar-based sauce or other products. Vinegar may also be considered a PLT if at least 1 log of Listeria death occurs before the product leaves the establishment, and the establishment can support this reduction. In addition, if the establishment can support that the vinegar results in at least a 5-log reduction of Lm after the product is placed in the final package, FSIS will consider the product to be nonpost lethality exposed.

2. Antimicrobial Processes (AMP) AMPs are operations, such as freezing, that are applied to an RTE product that have the effect of suppressing or limiting the growth of a microorganism, such as Lm, in the product throughout the shelf life of the product (9 CFR 430.1). Other examples are processes that result in a pH or water activity that suppresses or limits microbial growth. Examples of Antimicrobial Processes (AMPs) are the following:

- a. Fermentation
- b. Drying
- c. Freezing

FSIS requires establishments to provide adequate supporting documentation as part of any validation when using AMPs to control the growth of Lm (see Appendix 2.1 for more information on validation). Table 2.1 provides growth limits for Lm, which can be used to help evaluate the effectiveness of AMPs. If an AMP achieves conditions that would limit the growth of Lm based on the table, then the establishment can consider that the process has been validated to control growth of Lm.

Table 2.1 Growth Limits for Lm (ICMSF, 1996)

Temperature (°C)	Minimum	Optimum	Maximum
-0.4	31.3	37	45
\u00b0C	(31.3 \u00b0F)	(98.6\u00b0F)	(113 \u00b0F)
pH	4.39	7.0	9.4
Water activity	0.92	---	---

"FSIS Listeria Guideline January 2014 36 The establishment can place Table 2.1 on file as part of its supporting documentation, demonstrating that the AMP it has selected is sufficient to control growth of Lm, and no further scientific support for the process would be needed. However, the establishment should collect in-plant demonstration data in order to meet the second element of validation (see pages 34-35 for a discussion of in-plant demonstration data). In addition, the establishment would also be expected to conduct ongoing monitoring and verification activities to demonstrate that it is maintaining the conditions for pH, water activity, or temperature.

Example 1: Fermentation and Drying as an AMP

Fermentation and drying are processes that control the growth of Lm and other microorganisms by decreasing the pH and available moisture in the product. These processes are considered AMP if they result in finished product with pH or water activity that suppresses or limits the growth of Lm. FSIS will consider starter cultures used in dry or semi-dry fermented

sausages to be AMAs if the addition of the starter culture or vinegar results in a finished product with a pH of <4.6, and the establishment documents that this pH level in the specific product suppresses or limits growth of Lm. Although Table 2.1 lists a pH of 4.39, the pH of dry and semi dry fermented sausages may be higher (<4.6) and still control Listeria growth, because of the hurdle effect of the pH and low water activity (see Section 2.1 for more information about the hurdle effect). Example 2: Freezing as an AMP Another antimicrobial process that controls the growth of Lm in the post-lethality environment is freezing of RTE products. Freezing prevents the growth of any microorganisms in the product because their cellular activities are arrested, but depending on the method and length of freezing and other factors, some microbial kill can also result. Lm is more resistant to freezing than other foodborne pathogens and may survive freezing. Once the product is thawed, cellular activities of microorganisms may resume. It is important to note that freezing is only effective as an antimicrobial process while the product is frozen. If a product is distributed frozen and then thawed and sold as a refrigerated product, this would not meet the requirement in 9 CFR 430.1 that the antimicrobial treatment is effective throughout the shelf-life of the product. If the product is thawed as part of the preparation process by the consumer, the product will be deemed to have been frozen throughout its shelf-life. Ensuring the Effectiveness of AMAPs According to the Listeria Rule, establishments must document that the AMAP is effective in suppressing or limit growth of Lm over the shelf life of the product (9 CFR 430.4(b)(1)(ii)). The documentation should demonstrate that no more than 2-logs of growth occurs over the expected shelf-life of the product. The documentation for the effectiveness of the AMAP can be included in the establishment\u2019s HACCP plan, Sanitation SOP, or prerequisite program. Establishments may use published peer-reviewed papers, challenge studies, or in-house studies to support the effectiveness of AMAP. For more information on scientific supporting documentation, see Appendix 2.1. NOTE: Although Lm will not grow under the conditions in Table 2.1, it may still survive. In order to meet the conditions for a PLT, establishments would have to provide additional validation demonstrating that Lm is reduced or eliminated.", "FSIS Listeria Guideline January 2014 37 2.3 Sanitation All RTE establishments are required to maintain sanitation in their environment, according to 9 CFR 416. Sanitation is the foundation for an effective Listeria Control Program. Establishments in Alt. 3 rely on sanitation alone to control Lm in their post-processing environment; therefore, it is critically important that they maintain sanitary controls. They are also required to verify sanitation by testing food-contact surfaces for Lm or an indicator organism (see Chapter 3). Maintaining effective sanitation is also important for Alt. 1 and 2 establishments because PLTs and AMAPs are validated to provide certain levels of reduction or control growth of Lm. If levels of Lm are not controlled by proper sanitation, they could overwhelm the effectiveness of PLTs and AMAPs. Therefore, it is important that all establishments producing post-lethality exposed product maintain sanitation in their environments and verify its effectiveness. According to the Listeria Rule, sanitation measures for controlling Lm or an indicator organism may be incorporated into the establishment\u2019s HACCP plan, Sanitation SOP, or other prerequisite program. If Lm control measures are included in the Sanitation SOP, the effectiveness of the measures must be evaluated in accordance with 9 CFR 416.14. If sanitation measures are incorporated into a prerequisite program other than the Sanitation SOP, the establishment must ensure that the program is effective and does not cause the hazard analysis or the HACCP plan to be

inadequate. The establishment must include the program and the results produced by the program in the documentation that the establishment maintains, as required in 9 CFR 417.5. It is expected that establishments will develop procedures for both routine and intensified sanitation in the event that Lm or an indicator organism is found on a FCS or in the product. Sanitation actions should be escalated if repeated positives are found, indicating Listeria trends. See Chapter 4 and Appendix 2. 2 for more information on Listeria trends and sanitation.

Question: How do I maintain sanitation if my establishment produces raw and RTE product in the same room? Answer: In some instances, small and very small establishments may not have the physical space to have separate RTE and raw processing areas. There are numerous sanitation considerations for separating processes by time or space, such as:

Thoroughly cleaning and sanitizing between raw and RTE processing; Scheduling RTE processing on alternate days or scheduling RTE processing before raw processing; Using separate equipment for RTE and raw processing or scheduling equipment for RTE processing first, then for raw processing; Assigning different personnel for RTE and raw processing or having personnel clean hands thoroughly and use new coats, gloves, and hairnets and sanitized boots for RTE processing; Restricting movement of personnel during RTE processing; Using color-coded coats and locating coat racks for coats used in RTE area in designated space; Maintaining procedures for movement of personnel and equipment to prevent Listeria contamination; and Not allowing RTE product to come in contact with surfaces or raw products in coolers.", "FSIS Listeria Guideline January 2014 38 Reworked Product In some cases, establishments may rework product from previous shifts. Although this is an acceptable practice, reworked products may be more likely to be contaminated than other products because of the increased handling of the products. The establishment may also rework products that are returned from another location (e.g., an off-site warehouse). The establishment should have documented procedures as part of its hazard analysis to evaluate the returned product on receipt, to ensure it has not been temperature abused or otherwise contaminated before being returned to the establishment. In addition, the establishment should have sanitary controls in place as part of its Sanitation SOP to ensure that reworked product is not contaminated during reprocessing or repackaging of the product. Establishments would also need to take into account their production of returned and reworked product when developing their Listeria Control Programs (see Chapter 3) and determining what products to hold when FSIS samples products or food contact surfaces for pathogens.

2.4 Expected Levels of Control 1. Antimicrobial Agents and Post-lethality Treatments Table 2.2 shows the expected level of control (log reduction) for establishments using PLTs and AMAPs in Alt. 1 and 2.

Establishment validation studies or supporting documentation should demonstrate that these levels of control are achieved, at a minimum, in order for the PLT, AMAP to be considered effective (see Appendix 2.1 for more information on designing validation studies). As indicated in the table, establishments that achieve higher levels of control will be sampled relatively less by FSIS than establishments that achieve a lower level of control. Table 2.2 Expected Control Levels for Post-lethality Treatments and Antimicrobial Agents or Processes under Alternatives 1 & 2. [Levels of reduction or inhibition achieved to control Lm] Level of Control\ Treatment Increased Minimum Not Accepted Post-lethality Treatment (reduction should be achieved prior to distribution of the product into commerce) 2-logs or greater reduction At least 1-log reduction Less than 1-log reduction (At this level of reduction, the PLT is not eligible unless

there is supporting documentation) Antimicrobial Agent or Processes (growth must be limited over the shelflife of the product) Allows no more than 1-log growth Allows no more than 2-logs growth Allows greater than 2-logs growth (At this level of growth, the AMAP is not eligible unless there is supporting documentation)", "FSIS Listeria Guideline January 2014 39 How to use Table 2.2 For PLTs, the expectation is that establishments will achieve a minimum of at least a 1-log reduction in L<sub>m</sub> prior to distribution of the product into commerce. If the establishment achieves an increased level of control (a 2-log or greater reduction), they will be sampled less frequently by FSIS. If they do not achieve at least a 1-log decrease, the PLT would not be eligible as a PLT under the Listeria Rule unless there is supporting documentation. In addition, an establishment using a PLT achieving less than 1-log reduction would not be eligible to apply for the labeling claim regarding enhanced protection from L<sub>m</sub> (see Section 1.5). For AMAPs, the expectation is that establishments will demonstrate a minimum of no more than 2-logs of growth over the estimated shelf-life. If the establishment demonstrates an increased level of control (1-log or less of growth over the shelf-life), then FSIS will sample the product less frequently. If the establishment demonstrates more than 2-logs of growth over the shelf-life, then the AMAP would not be considered eligible as an AMAP for purposes of the Listeria Rule, unless there is further supporting documentation.

2. Sanitation Controls Regardless of which alternative an establishment chooses, per 9 CFR 430.4(c), establishments are responsible for maintaining their sanitation programs and may use microbial testing for L<sub>m</sub> or an indicator organism to verify the effectiveness of their sanitation program by testing foodcontact surfaces (FCSs). Establishments in Alt. 2b and 3 are required to test their FCSs to verify sanitation in the environment, and FSIS recommends that establishments in Alt. 1 and 2a test their FCSs, as well. As stated previously, establishments are expected to implement intensified sanitation, and escalate their sanitation actions in response to positive results. Information on intensified sanitation can be found in Appendix 2.2, and recommended testing frequencies to verify sanitation are discussed in Chapter 3.

2.5 Training A clearly written, fully-implemented training program is critical to the success of any food safety program designed to control Listeria. A Listeria Control Program, including implementation of HACCP and Sanitation SOP, will only be effective if employees understand the program, their role, and are able to perform the duties required of them in the program. This applies to new and existing employees involved in all stages of production, from sanitation to food handling to record keeping. Individuals that develop or reassess or modify HACCP plans must be trained in accordance with 9 CFR 417.7(b); however it is important that all employees be trained in basic sanitation. An establishment's Listeria training program should include a broad, basic training program for all employees regardless of their job duties, as well as more specialized training programs for employees that handle product and staff involved in cleaning and sanitation. In some cases, employees that may be involved in more than one of these activities should be trained appropriately. The training should be tailored to meet specific needs of the establishment.

NOTE: Establishments producing products that allow greater than 1-log growth of the pathogen during its shelf life will not be eligible to apply for the labeling claim regarding enhanced protection from L<sub>m</sub>.", "FSIS Listeria Guideline January 2014 40 For more information on developing training programs, see Appendix 2.3.

2.6 New Technology and New Ingredient Review FSIS believes that the facilitation of the use of new technology and new ingredients represents an important means of improving the safety of meat, poultry, and egg products. The

Agency defines "new technology" and "new ingredients" as new ingredients or technologies or new applications of equipment, substances, methods, processes, or procedures affecting the slaughter of livestock and poultry, and processing of meat, poultry, and egg products. FSIS evaluates whether new technology and new ingredients affect product safety, inspection procedures, inspection program personnel safety, or if they would require the waiver of a regulation. Substances used as new technology or new ingredients must also meet the requirements for safety and suitability under the Agency's food ingredient approval process. While the Food and Drug Administration (FDA) has the responsibility for determining the safety of food ingredients and additives, as well as prescribing safe use, FSIS has the authority to determine that new ingredients and new uses of ingredients are suitable for use in meat, poultry, and egg products. FDA and FSIS have a Memorandum of Understanding (MOU) regarding the review, approval, and listing of food ingredients and sources of radiation used in the production of meat, poultry, and egg products. This agreement establishes the working relationship to be followed by FSIS and FDA in responding to requests for the sanctioning of the use of food ingredients and sources of radiation subject to regulation by FDA and intended for use in the production of meat, poultry, and egg products. This review is normally done simultaneously by both agencies. The MOU information can be found at: Memorandum of Understanding between FDA and FSIS

The FSIS Innovations (New Technology) Staff within the Risk, Innovations, and Management Division (RIMD) in the Office of Policy and Program Development (OPPD) reviews new technology and new ingredients that can be applied in meat, poultry, and egg processing to facilitate the introduction of the new technology in establishment or plant operations. New technology and new ingredients for use on post-lethality RTE meat, poultry, and egg products to control the growth of Lm should be sent to the New Technology Staff for review. FSIS issued the document "Guidance Procedures for Notification and Protocol Submission of New Technology" to aid in the submission of applications for review of new technology and new technologies by FSIS. Those to which FSIS has "objection" to their use in FSIS establishments are posted on the FSIS website at: New Technology Tables. A listing of ingredients that have been reviewed and approved by FDA and FSIS are available in 9 CFR Part 424, Subpart C, 424.21 "Use of food ingredients and sources of radiation." This regulatory listing of approved ingredients is now updated quarterly through revisions of FSIS Directive 7120.1 "Safe and Suitable Ingredients Used in the Production of Meat, Poultry, and Egg Products" to expedite the posting of new approved substances.

NOTE: A clearly written, fully-implemented training project is critical to the success of any Listeria Control Program. A Listeria Control Program will only be effective if employees understand the project, understand their roles, and are able to perform the duties required of them in the project."

"FSIS Listeria Guideline January 2014 41

The above technology and ingredient reference resources should be used when considering the use of a technology or ingredient.

2.7 Glossary

Antimicrobial Agent (AMA): A substance in or added to an RTE product that has the effect of reducing or eliminating a microorganism, including a pathogen such as Lm, or that has the effect of suppressing or limiting growth of a pathogen, such as Lm, in the product throughout the shelf life of the product. Examples include potassium lactate and sodium diacetate, both of which limit the growth of Lm (9 CFR 430.1).

Antimicrobial Process (AMP): An operation, such as freezing, applied to an RTE product that has the effect of suppressing or limiting the growth of a microorganism, such as Lm, in the product

throughout the shelf life of the product (9CFR 430.1). Antimicrobial agents and processes are referred to together as (AMAP). Log Reduction: A 90% reduction of a pathogen. For example, a 2-log<sub>10</sub> reduction is a 99% reduction of a pathogen. Post-lethality Treatment (PLT): A lethality treatment that is applied or is effective after postlethality exposure. It is applied to the final product or sealed package of product in order to reduce or eliminate the level of pathogens resulting from contamination from post-lethality exposure (9 CFR 430.1). Prerequisite Program: A procedure or set of procedures that is designed to provide basic environmental or operating conditions necessary for the production of safe, wholesome food. It is called \u201cprerequisite\u201d because it is considered by scientific experts to be prerequisite to a HACCP plan (9 CFR 430.1). Rework: Rework is the process of recooking, reprocessing, or repackaging the product. This could also include temporary packaging of the product. FSIS considers any process that removes the product from the package and exposes it to the environment as rework. Sanitation Standard Operating Procedure (Sanitation SOP): Written procedures for sanitation that describe all of the procedures the establishment will perform daily, before, and during operations, sufficient to prevent direct contamination or adulteration of products, according to 9 CFR 416.12(a).

April 26, 2010.Industry Guidelines to Prevent Contamination from Listeria monocytogenes", "FSIS Listeria Guideline January 2014 46 Attachment 2.1: Post-Lethality Treatments NOTE: Mention of trademarks or commercial names does not constitute endorsement by USDA. I. Steam Pasteurization and Hot Water Pasteurization Post processing contamination of RTE meat and poultry is mostly confined to the surface. Pasteurization by steam and hot water acts on the surface microbial contaminants by the action of heat. Studies on surface pasteurization using steam or hot water were shown to be effective in reducing this contamination. Studies by Murphy et al., (2003a) showed that post-cook hot water pasteurization and steam pasteurization resulted in a 7 log<sub>10</sub> reduction of Lm in inoculated vacuum packaged fully cooked sliced chicken. The reduction was effective when single\u2013packaged breast fillets, 227 gm- packaged strips, and 454 gm-packaged strips were heat treated at 90\u00ba C in a continuous steam cooker or hot water cooker for 5, 25, and 35

minutes respectively. These investigators developed a model called ThermoPro that could predict the thermal lethality of pathogens in fully cooked meat and poultry products during post-cook in-package pasteurization (Murphy et al., 2001, 2003b, 2003c). The model was developed using *L. innocua* and verified for *Lm*. Information gathered from the summary or abstract: Post-lethality treatment: hot water pasteurization or steam pasteurization Products: fully cooked chicken breast fillets and strips Procedure: fully cooked products were surface inoculated with *Lm*, vacuum packaged and pasteurized Equipment used for the pasteurization treatment: Steam pasteurization: pilot-scale steam cooker Hot water pasteurization: pilot-scale hot water cooker Temperature of pasteurization: 90\u00b0C Reduction of *Lm*: 7-log reduction Products and time of pasteurization that resulted in 7-log reduction Product Time of pasteurization (min) Single-packaged breast fillets 5 227g-package strips 25 454 g-packaged strips 35 II. Pre-Package Pasteurization and Post-Package Surface Pasteurization Pre-package surface pasteurization treatment of fully cooked meat removed from its packaging wrap and inoculated with *Lm* resulted in a 1.25 to 3.5-log reduction with a treatment time of 60120 sec at 475 to 750\u00ba F air temperature (Gande and Muriana, 2003). Surface pasteurization was applied on cooked whole and split roast beef, whole corned beef, and whole and formed ham using a radiant oven. Pre-package pasteurization (60 sec) combined with post-package submerged water pasteurization using formed ham (60 or 90 sec), turkey bologna (45 or 60 sec), and roast beef (60 or 90 sec), resulted in a 3.2 to 3.9-log reduction for ham, 2.7 to 4.3-log reduction for bologna, or a 2.0 to 3.75-log reduction for roast beef. The level of reduction varied depending on the method of inoculation, type of product used, treatment temperature, and residence time." , "FSIS Listeria Guideline January 2014 47 Muriana et al., (2002) used a stainless steel water bath to submerge cooked RTE deli-style whole or formed turkey, ham and roast beef, removed from their package, inoculated with *Lm* and vacuum packaged. Results show a 2 to 4-log decrease in the levels of *Lm* in inoculated products post-cooked at 195-205\u00ba F for 2-10 min. Treatment of processed foods with acidified sodium chloride (ASC) is another example of prepackaging treatment. ASC is an antimicrobial agent that is approved for use on processed meat food products (unless precluded by standards of identity in 9 CFR 319), prior to packaging of the food for commercial purposes (21 CFR 173.325(f)). It is applied as a dip or spray at levels that result in a sodium chlorite concentration of 500 to 1,200 ppm in combination with any GRAS acid at levels sufficient to achieve a pH of 2.5 to 2.9. It is approved as a secondary direct food additive and considered as a processing aid, with very temporary or short term technical effect (bactericidal antimicrobial activity), after which it rapidly degrades to leave no long term residues or actives remaining (Kemp, Alcide Corp., personal communication, 2003). Because of this, it does not have to be included in the ingredient listing of the label. Marsden et al. (2000, unpublished), evaluated sodium chlorite (1,200 ppm) with 0.9% citric acid for its effectiveness in reducing *Lm* on retail sausages. Results show that a water wash gave a 1.2-log reduction of *Lm*. An ASC dip for 15 sec provided a 1.0-log reduction better compared to water wash. ASC exposure time of 30 sec gave 1.1 and 1.6-log reductions over the water wash control, for spraying and dipping, respectively. Spray wash or dipping was found to be comparable in antibacterial effectiveness against *Lm*. II. High-Pressure Processing High-pressure processing (HPP) is a technology that subjects food to elevated pressures, with or without the addition of heat, to inactivate microorganisms and extend microbiological shelf life. This technology provides a means of ensuring food safety for those products that are difficult to

heat treat due to organoleptic effects. HPP was shown to inactivate pathogens without any thermal or chemical effects and, at the same time, preserve the quality of the product.

Raghubeer and Ting (2003) evaluated the efficacy of HPP in inactivating Lm in retail packaged samples of sliced ham, turkey, and roast beef obtained from a manufacturer, and repackaged in 25-g portions. Results show that an inoculum of about 10<sup>4</sup> Lm cocktail in these 3 products and HPP treatment at 87,000 psi for 3 minutes showed no recovery of Lm after 61 days of storage at 34°F. No pressure-injured cells were detected. No adverse organoleptic effects were detected on the 3 HPP treated products during the 61-day shelf life study. No signs of spoilage were seen on all 3 products after 61 days of storage, and for 100 days for ham and turkey.

According to the investigators, the normal shelf life of these products is 30 days, so the HPP treatment extended the shelf life of the products.," "FSIS Listeria Guideline January 2014 48 Attachment 2.2: Antimicrobial Agents or Processes I. Use of Antimicrobial Ingredients including Bacteriophages, Lactates, Acetates, Diacetates, and Ozone Bacteriophages are viruses that infect bacteria, and cause cell death. Bacteriophage preparations may be sprayed on RTE products to reduce or eliminate Lm. These preparations (a mixture of equal proportions of six different individually purified lytic-type bacteriophages specific against Lm) are applied as a spray at a level not to exceed 1 ml of the additive per 500 cm<sup>2</sup> product surface area.

Guenther et al., (2009) showed that Lm pathogen-specific bacteriophages could reduce bacterial counts by up to 5 logs when applied to the surface of hot dogs (sausages) and sliced turkey breast (cold cuts). Ozone is an antimicrobial gas usually applied in an aqueous solution to products, food contact surfaces as a continuous spray (e.g., belts, moving tables), and non food contact environmental surfaces. Currently, the use of ozone is permitted by FDA and FSIS (21 CFR 173.368, FSIS Directive 7120.1) for use with all meat and poultry products, including RTE meat and poultry products. Buege et al., (2004) showed 1.0 to 2.4 log reductions (average 1.5) of Lm when 0.6 ppm ozone for 30 seconds was applied to ham, salami, meatloaf, natural casing wieners, and skinless wieners. Studies have shown that lactic acid and acetic acid have significant antimicrobial activity in broth and food systems. Sodium and potassium salts of these acids, when added to processed-meat formulations, are also known to potentially inhibit pathogenic bacteria, especially Lm. These antimicrobials inhibit growth of pathogens by inhibiting their metabolic activities. Seman et al., (2002) developed a mathematical model capable of predicting the growth or stasis of Lm in commercial cured meat products using a response surface method. The model can be used by manufacturers in the determination of the appropriate amounts of potassium lactate and sodium diacetate to be added to cured meat products that are organoleptically sensible and will not support the growth of Lm. Thirty products were formulated by using a variety of raw material sources such as pork trimmings, trimmed turkey breast halves, and four-muscle ham. Varying amounts of potassium lactate and sodium diacetate were added to the meat formulation and the meats were processed into different products. After chilling, the products were stripped of their casings, sliced into 25-g slices, placed into pouches, and inoculated with Lm by applying it to the surface of 100g of cured meat (four slices). Sodium chloride content was found to have a negative correlation to growth rate. The investigators provided a final regression equation predicting the growth of Lm in cured RTE meat products stored at 4°C. The investigators used predictive model performance factors and a simple linear regression analysis to evaluate the model generated in this study. They verified the accuracy of the model by comparing it with actual Lm growth data

from an independent challenge study conducted with four different commercial RTE meat products using similar storage conditions. Performance factors calculated and evaluated for control products (those","FSIS Listeria Guideline January 2014 49 not containing potassium lactate and sodium diacetate) indicated that on the average, the predicted growth of Lm exceeded those of the observed values by about 24%. The study also emphasized the importance of moisture content in the application of lactates and diacetates as antimicrobial agents. The article reports that \u201cThe results show that increasing amounts of potassium lactate syrup and sodium diacetate decreased the growth rate of Lm, while increasing finished product moisture increased the growth rate. Sodium chloride content was not significant but was found to have a negative correlation to growth rate. This study provided a useful model in determining the target amounts of potassium lactate and sodium acetate for cured meat product formulations to inhibit the growth of Lm. The calculations would also require knowledge of the finished product sodium chloride and moisture contents.\u201d Table 2 from the study shows that different finished product moisture levels, amount of sodium chloride, and lactate and diacetate result in different levels of Lm growth rate.

% Salt	% Sodium Diacetate	% Potassium Lactate Syrup	% Product Moisture	Lm Growth Rate (wk -1 )
1.50	0.15	7.0	74.0	0.0
1.50	0.05	2.5	74.0	0.0991
2.20	0.20	4.75	64.5	0.0
2.20	0.10	0.25	64.5	0.1338

The investigators advised that this validated model is specific to the products designed for the study and the Lm strains used. Testing of this model in other environments and with other Listeria spp., and to formulations that are outside the model\u2019s limits may result in different maximum growth rates. This study (Seman et. al., 2002) provided a useful model in determining the target amounts of potassium lactate and sodium acetate for cured meat product formulations to inhibit the growth of Lm. The calculations would also require knowledge of the finished product sodium chloride and moisture contents. The investigators advised that this validated model is specific to the products designed for the study and the Lm strains used. Testing of this model in other environments and with other Listeria spp., and to formulations that are outside the model\u2019s limits may result in different maximum growth rates. This study was used as the basis for the Opti.Form Listeria Control Model. The Opti.Form Listeria Control Model is a unique tool used to calculate the levels of lactate and diacetate required to retard the growth of Lm in cured meat and poultry products. The model is based on the study detailed in the paper by Seman et al., 2002, above. The model includes: \u2022 Instructions on how to use the model, \u2022 Explanation on the development of the model, \u2022 Information on the anti-microbial effects of lactate and diacetate, Recall Alert An investigation of a 2007 recall of RTE cooked chicken products contaminated with Lm showed that the establishment failed to maintain sanitation, and antimicrobial agent failed to suppress Lm. The moisture levels were higher in the product than in the establishment\u2019s supporting documentation, which could have allowed Lm growth.", "FSIS Listeria Guideline January 2014 50 \u2022 Lactates and diacetates and use of these products, \u2022 Regulations and labeling, and \u2022 Literature references. The model can be accessed by visiting the Purac website at:  
<http://www.purac.com/EN/Food/Calculators/Listeria-Control-Model.aspx>

Bedie et al., (2001) evaluated the use of antimicrobials, including in frankfurter formulations, on Lm populations during refrigerated storage. Fully cooked and cooled frankfurters were inoculated with 103 to 104 CFU /cm<sup>2</sup> of Lm after peeling and before vacuum packaging. Samples were stored at 4\u00b0C for up to 120 days and sampled for testing on assigned days. Results were

as follows: Antimicrobial Level (%) Lm Growth Inhibition Sodium lactate 3 70 days no pathogen growth Sodium diacetate 0.25 50 days no pathogen growth Sodium acetate 0.25, 0.50 20 days no pathogen growth Sodium lactate 6 120 days no growth and reduced pathogen growth Sodium diacetate 0.5 120 days no growth and reduced pathogen growth Inoc. Control 0.0 Increased to 6 logs in 20 days Note: Sodium acetate is approved as a flavor enhancer, not as an antimicrobial agent. No pathogen growth refers to zero increase in the number of inoculated Lm cells (bacteriostatic), while reduced pathogen growth refers to a decrease in the number of inoculated Lm cells (bactericidal) in the product. In this study, tables showed that the reduction varied with storage days, but was up to 1.0 log on some days. Antimicrobials were found to have no effect on pH, except for sodium diacetate, at 0.5%, which reduced the initial pH. Using the formulations and conditions in the study, establishments can add 3% sodium lactate in the frankfurter formulation and obtain no growth of Lm up to 70 days at refrigerated storage of 4°C. If the lethality treatment is adequate to eliminate Lm, then the only probable source of Lm would be from exposure of the product during peeling and repackaging. However, the establishment's sanitation program may keep the numbers to a very low level, and 3% sodium lactate included in the formulation would inhibit the growth of Lm during the product's refrigerated shelf life. Levels of sodium lactate at 6.0% and sodium diacetate at 0.5% showed a reduction of the pathogens; however, these levels are above the permitted levels. A study by Samelis et al., (2002) used similar treatments, processing, and inoculation procedures and frankfurter formulations as the previous study described above. However, in this study, combinations of antimicrobials were used, and in combination with hot-water treatment. Hot-water treatment involved immersion of frankfurters, with two product links in a package to 75 or 80°C for 60 sec. Storage at 4°C yielded the following results:

Treatment Levels (%)	Lm Growth	Inhibition	Sodium lactate	1.8	35-50 days	no growth	Sodium lactate + sodium acetate	1.8	0.25	120 days	no growth; 35-50 days growth reduction	Sodium lactate + 1.8	120 days	no growth; 35-50 days growth", "FSIS Listeria Guideline January 2014 51		
Sodium diacetate	0.25	reduction	Sodium lactate + Glucuno-deltalactone	1.8	0.25	120 days	no growth, 35-50 days growth reduction	Hot water treatment (80°C, 60 s)	+ Sodium lactate	1.8	Inoc. population reduced by 0.4-0.9 log CFU/cm <sup>2</sup> , and 50-70 days growth reduction by 1.1-1.4 CFU/cm <sup>2</sup>	Hot water treatment (80°C, 60 s)	Increase in growth to about 6-8 logs in 50 days	Inoculated Control, no treatment	Increase in growth to about 6 logs in 20 days and 8 logs thereafter up to 120 days	Note: Sodium lactate was used as a 3% of a 60% (wt/wt) commercial solution. Glucuno-delta lactone is approved as an acidifier and a curing accelerator, but not as antimicrobial. Sodium acetate is approved as a flavor enhancer, not as an antimicrobial agent. Glass et al., (2002) evaluated sodium lactate and sodium diacetate on wieners and cooked bratwurst containing both beef and pork supplied by a commercial manufacturer. Antimicrobial solutions used were sodium lactate and sodium diacetate singly or in combination at varying concentration. Wieners were repackaged in gas-impermeable pouches, then surface-inoculated with Lm mixture on multiple areas of the surface of each link. Packages were vacuum-sealed and stored at 4.5°C for up to 60 days. Two types of cooked bratwurst from a commercial manufacturer were evaluated: bratwurst that was cured and naturally smoked and bratwurst that was uncured and unsmoked. Bratwurst was stored at 3 or 7°C for up to 84 days. The surface treatment, consisting of dipping wieners into solutions containing up to 6% lactate and up to 3% diacetate for 5 seconds, did not delay

pathogen growth, indicating that dipping wieners in the lactate\diacetate solutions is not an efficient way to apply the antimicrobials. However, the inclusion of lactates and diacetates in the formulation was found effective in inhibiting growth of Lm. Results were as follows:

Product	Sodium Lactate (%)	Sodium Diacetate (%)	Lm Levels (CFU\pkg)	Bratwurst uncured, unsmoked
3.4	2.0	0.1	0.0	Growth delayed for 4-12 weeks at 7 and 3\u00b0C storage, respectively.
3.4	0.0	0.1	0.0	Growth inhibited for 12 weeks at 7 and 3\u00b0C
Wieners	3.0	1.0	0.0	Growth inhibited for 60 days at 4.5\u00b0C
				Growth inhibited for 60 days at 4.5\u00b0C

A study by Porto et al., (2002) used freshly processed peeled frankfurters in vacuum sealed packages obtained from a commercial manufacturer. Two formulations of links were used in the study: one with added 2 or 3% potassium lactate and the other without added potassium lactate. Frankfurters were aseptically removed from their original package, repackaged, and inoculated", "FSIS Listeria Guideline January 2014 52 with a mixture of Lm. The packages were vacuum-sealed to 95 kPa and incubated at 4 and 10\u00b0C. Results show that the addition of 2% or 3% potassium lactate in frankfurters can appreciably enhance safety by inhibiting or delaying the growth of Lm during storage at refrigeration or abused temperatures. The viability of the pathogen was influenced by pH and the levels of lactate added, but not by the presence of indigenous lactic acid bacteria.

Potassium Lactate (%)	Inoculum CFU\pkg	Storage Temp. (\u00b0C)	Days	Storage Lm Levels (CFU\package)
2.0	20	4	90	Remained at about 1.6 log 3.0
2.0	20	4	90	Remained at about 1.4 log 3.0
4.0	90	4	90	Remained at about 2.4 log 0.0
4.0	90	4	90	Increased to about 4.6 log 0.0
4.0	90	4	90	Increased to about 5.0 log 2.0
10	60	10	60	Remained at about 1.4 log 3.0
10	60	10	60	Remained at about 1.1 log 0.0
20	60	20	60	Increased to about 6.5 after 28 days, declined to about 5.0 after 60 days
20	60	20	60	Remained at about 2.4 log 0.0
50	20	60	60	Increased to about 6.6 log after 40 days and declined to about 5.5 log after 60 days II.

Growth Inhibitor Packaging Growth-inhibitor packaging is an intervention which delivers an active antibacterial agent to the surface of an encased sausage product. By incorporating this special coating onto the internal surface of cellulose casings, the antilisterial treatment is transferred to the surface of the processed meat\sausage during thermal processing. Upon removal of the casing, the treatment remains active on the meat surface, providing effective protection against inadvertent Listeria contamination during subsequent peeling and packaging processes. Growth-inhibitor packaging, used in conjunction with functional HACCP and Good Manufacturing Practices, provides the industry with one more tool to control the risk of Lm contamination of RTE meat and poultry products. Studies on meat formulations for hotdogs using NOJAX\u00ae AL\u2122 (Viskase Corporation, 2003) showed that the use of the casings provide a lethality hurdle to the growth of Lm, not just an inhibitory effect. The lethality impact is delivered within the first hours\days of the sausage\hotdog package life. This impact is dependent on many variables, but is generally in the range of 1 \u2013 2 log decrease of Lm at high levels of inoculation. This performance has been observed in challenge studies conducted on hotdogs drawn from commercial full-scale trials at a number of commercial processing plants. In high-inoculation trials, NOJAX AL has been combined with conventional growth inhibiting additives, and the lethality impact is obtained and then maintained throughout the product life cycle. In these same trials, without growth inhibiting additives, this casing produces lethality but in several weeks the remaining Lm begin to grow. NOJAX AL is available in the U.S., and has been approved by both FDA and USDA for its key component, nisin. This GRAS

component must be included in the ingredient statement via a label change request to the FSIS Labeling and Program Delivery Division. Because this is a", "FSIS Listeria Guideline January 2014 53 naturally derived polypeptide, there are storage and use-by criteria that will have to be adhered to by the user for maximum benefit. Casing shelf-life is about 60-90 days, with a not to exceed temperature of 85\u00ba F. This technology can be applied to most hotdogs and sausages that are encased in cellulose casing. This casing intervention can be used in any instance where casing is used as a mold for processed meat and poultry during thermal processing. This would include cellulose, plastic, and, possibly, natural casing. As part of a manufacturer\u2019s decision to use this technology, benefits are: 1) no capital costs or new equipment; 2) no change in processing steps or plant reconfigurations; 3) no impact on flavor, texture, or package appearance, and 4) minor labeling change to ingredient statement. Since this is a surface treatment, cost will be proportional to the surface to volume ratio of the product: the larger the sausage diameter, the lower the cost per pound. In general, economic analyses put the cost of this lethality intervention at about 2-3 cents per pound of finished product, with a mid-range target price of 2.5 cents per pound for a traditional 10-to-the-pound retail pack of hotdogs. Janes et al., (2002) investigated the effect of nisin added to zein film coatings (Z) coated onto cooked RTE chicken against Lm. Cooked chicken samples inoculated with Lm were dipped into Z dissolved in propylene glycol or ethanol, with or without added nisin (1,000 IU/g) and/or 1% calcium propionate and stored at 4\u00b0C or 8\u00b0C for 24 days. After 16 days at 4\u00b0C, Lm was suppressed by 4.5 to 5 log CFU/g with zein film coatings with nisin. The most effective treatment in the study for controlling Lm on the surface of RTE chicken was found when using edible zein film coatings containing nisin at a storage temperature of 4\u00b0C. A processing plant would use film coatings by fully processing the meat products, then coating them with the films. Coating can be done by spraying or dipping the processed meat products and then allowing them to dry. Zein coatings on the meat products can be dried by circulating air around the meat product using a fan. Finally, the dried coated meat products can be packaged with the usual plastic film material and refrigerated. The study by Janes et. al. has not been tested in commercial poultry processing conditions. Some general observations from the published studies on antimicrobials: \u2022 Lactates, acetates, and diacetates were found more effective in inhibiting growth of Lm when used in combination than when used singly. \u2022 These antimicrobials (described in the guideline) were found more effective when used to the maximum allowable concentration. However, higher concentrations of antimicrobials used in the formulation may affect the sensory qualities of the product, such as flavor and texture, which would necessitate sensory evaluation of treated products. \u2022 When used in combination, the amount needed to inhibit growth may be reduced. \u2022 These antimicrobials were found to have listeriostatic activity more than listericidal activity, i.e., they prevent growth of the pathogen more than reduce the number of cells of the pathogen, and therefore may not be effective against gross contamination of a product. The establishment\u2019s sanitation program should control gross contamination of", "FSIS Listeria Guideline January 2014 54 the processing environment and equipment. Addition of antimicrobials would be effective only as part of the overall HACCP strategy. \u2022 Including these antimicrobials in the formulation was found to be more effective in inhibiting listerial growth than dipping products in solutions of antimicrobials. \u2022 The antimicrobial activity of lactates and diacetates when used singly or in combination is affected by the level of

contamination of the meat product surface and processing factors such as pH, moisture, water activity, fat, nitrite, salt content, time and temperature of storage, and packaging atmosphere. \u2022 Application of the treatments used in these studies is limited to the formulations, products, and treatments used in the studies. Applying these studies to other products and formulations may result in different rates of growth inhibition. Therefore, the establishment should verify the effectiveness of the antimicrobials used in these studies for other processed meat products and other storage temperatures. \u2022 Antimicrobials used in the formulation should have an effective antilisterial activity throughout the commercial shelf life of the product. Currently, the targeted commercial shelf life of refrigerated cooked meat products in the U.S. is 75 to 90 days. \u2022 Using post-packaging thermal treatments in addition to antimicrobials was found to increase the total antilisterial effects of the antimicrobials. \u2022 These antimicrobials were found to be more effective in smoked products formulated with sodium nitrite or in products stored at strict refrigeration temperatures. \u2022 These antimicrobials may be a cost-effective antilisterial method that very small establishments can use.", "FSIS Listeria Guideline January 2014 55 Appendix 2.1 Validation I. Validation II. Scientific Support 1. Published Processing Guidelines 2. Scientific Articles from a Peer-Reviewed Journal 3. Challenge or Inoculated-Pack Studies 4. Validated Predictive Microbial-Modeling Programs 5. Establishing the Shelf-life of the Product III. In-plant Demonstration IV. Validation Examples I. Validation Validation is the process of demonstrating that the HACCP system as designed can adequately control identified hazards to produce a safe, unadulterated product. There are two distinct elements to validation: 1) The scientific or technical support for the HACCP system (design). This consists of having scientific and technical documentation that demonstrates that the designed process can control the identified hazard. In other words, will the HACCP work in theory? 2) The initial practical in-plant demonstration proving the HACCP system can perform as expected (execution). This consists of having records that demonstrate that the HACCP plan achieves what it is expected to achieve. In other words, does the plan work in practice? Validation encompasses activities that make up the entire HACCP system. Validation is an important component to the development of a HACCP system but has particular importance for products produced under the Listeria Rule. Validation, as it relates to the requirements in the Listeria Rule, will be covered in this Appendix. In particular, considerations for scientific support and in-plant data for AMAPs, and PLTs will be covered. Further recommendations can be found in the FSIS Compliance Guideline: HACCP Systems Validation, May 2013. II. Scientific Support The first element of validation is scientific support (design). There are several types of scientific support that would be considered acceptable for validating an AMAP, PLT, or other treatment. These include: \u2022 Published processing guidelines \u2022 Regulatory performance standards Question: Can establishments use the studies cited in the Compliance Guidelines for validation as they use the Compliance Guidelines in Appendices A and B in the Final Rule for certain meat and poultry products to validate cooking and cooling (stabilization) processes? Answer: Yes, provided the product, processing procedures, and ingredients are equivalent to those in the studies. For example, if the pH and concentration of antimicrobial in the study were both considered critical, then the product must have that pH and contain the antimicrobial in the concentration used in the study.", "FSIS Listeria Guideline January 2014 56 \u2022 A scientific article from a peer-reviewed journal, \u2022 A challenge or inoculated-pack study, \u2022 Unpublished data gathered in-house, and \u2022 Validated predictive microbial-

modeling program. The scientific documentation should identify: \u2022 The purpose, \u2022 The experimental procedure (including microbial testing methodology), \u2022 The hazard studied, \u2022 The product type, size, formulation, and composition (i.e., water activity, pH, fat, moisture level, salt level, and if applicable, antimicrobial level), \u2022 The processing steps that will achieve the specified reduction or prevention of growth of the pathogen, and \u2022 The critical operational parameters (i.e., the factors affecting microbial reduction in the processor\u2019s HACCP system), including: \u2022 The model and type of equipment, \u2022 Concentration, \u2022 Time, \u2022 Temperature, and \u2022 Pressure. \u2022 How the critical operational parameters can be monitored, and \u2022 The level of reduction or prevention achieved by the post-lethality treatment or antimicrobial agent applied. Question: What records would the Agency require for products with formulations that are inherently antilisterial, but that may not be formulated specifically for that purpose (e.g., BBQ and pickled meats, precooked bacon, beef snack sticks)? Would the establishment be required to make changes to the HACCP plan, Sanitation SOP, or prerequisite project to account for the antilisterial benefit of the formulation\process? Answer: FSIS would expect the establishment to have scientific support (e.g., citations to published data) that the product characteristics (e.g. moisture level, pH, or salt levels) result in at least a 1-log decrease of Listeria. Inclusion of the process in the HACCP plan would only be required for a PLT. If the process controls Listeria growth, it could be included in the Sanitation SOP or prerequisite project. Question: Does an establishment need to provide additional validation information beyond what is in the Compliance Guidelines with regard to freezing, pH and water activity to satisfy the first part of validation, scientific support? Answer: No. The establishment needs to validate the process in relation to L<sub>m</sub>, except when these values are below the limit of L<sub>m</sub> growth: pH below 4.39, water activity below 0.92, and temperature below -0.4\u00b0C, as stated in the Compliance Guidelines. However, the establishment must have the supporting documentation on-file and must conduct monitoring and verification activities.", "FSIS Listeria Guideline January 2014 57 Care should be taken to ensure that the scientific support documents are sufficiently related to the process, product, and hazard identified in the hazard analysis. The supporting documentation should be complete and available for review. Failure to take these steps would raise questions about whether the HACCP system has been adequately designed and validated. To be effective, the process procedures should relate and adhere to the critical operational parameters in the supporting documentation. Critical operational parameters are those parameters of an intervention that must be met in order for the intervention to operate effectively and as intended. Critical operational parameters include product type or size, the type of equipment, time, temperature, pressure, and other variables used in the study needed to result in equivalent levels of reduction of L<sub>m</sub>. It is important that the critical operational parameters in the establishment\u2019s actual process match those in the scientific support because such characteristics affect the PLT efficacy; for example: pH, water activity, and the presence of preservatives may all affect the PLT efficacy. If one or more of the parameters are not addressed in the process or if one or more parameters differ from those used in the scientific support, then the establishment should document a justification for the differences. 1. Published Processing Guidelines This guideline (the FSIS Listeria Guideline) is an example of a published processing guideline that can provide adequate supporting documentation for an establishment\u2019s control processes for L<sub>m</sub>. For example, Table 2.1 contains growth limits

for Lm, which can be used by establishments to help support the effectiveness of AMPs. If an AMP achieves conditions that would limit the growth of Lm based on the table, and the establishment meets the other criteria in the guidelines that would limit pathogen growth (e.g., maintaining sanitation), then the establishment can consider that the process has been validated to control growth of Lm. The establishment can place Table 2.1 on file and no further scientific support for the process would be needed. However, the establishment should collect in-plant demonstration data in order to meet the second element of validation (see pages 34-35 for a discussion of in-plant demonstration data). In addition, Attachment 2.1 and Attachment 2.2 contain summaries of journal articles that may be used to support the efficacy of PLTs or AMAPs, respectively. These attachments are not considered adequate support on their own, however, because they do not provide the details of each study that an establishment needs to determine if the study is representative of the actual process. For this reason, if an establishment chooses to use one of the articles provided in Attachment 2.1 or Attachment 2.2., FSIS expects that the establishment will have a full copy of the original article on file. Establishments may also keep Table 3.1 on file to support that they are meeting the requirements of the Listeria Rule related to Alternative 2, Choice 2 (2b) and Alternative 3 processes. Establishments can keep this table on file as part of the supporting documentation needed to explain why the testing frequency they have selected is sufficient to control Lm or an indicator organism according to 9 CFR 430.4(b)(2)(iii) (E) and (3)(i)(E). In addition, both Appendix A and Appendix B of the final rule, "Performance Standards for the Production of Certain Meat and Poultry Products", FSIS Guidance on Safe Cooking of Non-Intact Meat Chops, Roasts, and Steaks, April 2009 and the Time-Temperature Tables for Cooking Ready-to-Eat Poultry Products may be used to support the reprocessing of contaminated products, as described in Section 4.4. Although Appendix A, the FSIS Guidance on Safe Cooking of Non-intact Meat Chops, Roasts, and Steaks, and the Time-Temperature", "FSIS Listeria Guideline January 2014 58 Tables for Cooking Ready-to-Eat Poultry Products are designed to achieve reductions in Salmonella, establishments are not expected to validate that these processes also achieve reductions in Lm because Salmonella is considered an indicator of lethality for Lm. 2. Scientific Data\Information Peer-reviewed scientific data that describes a process and the results of the process can provide adequate supporting documentation for the establishment\u2019s process. This type of support could include journal articles, graduate student theses, or information found in a textbook. All of these types of scientific data go through a process of evaluation involving qualified individuals within the relevant field. In addition to describing the microbiological results of the process, the data may describe the role intrinsic and extrinsic product factors play on the growth of microorganisms. For example, a textbook may contain data on the growth limits of certain pathogens based on a food product\u2019s water activity and pH. For journal articles, the study should relate closely to the establishment\u2019s process with regards to species, product characteristics, and equipment. The establishment should use the critical operational parameters (see Section II above), cited in the journal article, that achieve the required or expected lethality or stabilization. If the establishment uses parameters that differ from those cited in the journal article, it should provide additional support for those parameters. For biological hazards, the scientific article should contain microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis. A lack of microbial data in the

scientific support could raise questions concerning whether the process design has been adequately validated. There are a number of published journal articles, theses, or textbooks available that can be accessed on-line or through a library system. Again, the establishment should ensure that the study closely relates to the establishment's process. An establishment that uses products, treatments or variables other than those used in the referenced studies should perform its own studies (or use another method of scientific support) to ensure effective reduction of L<sub>m</sub>. For example, if a published study uses a ham product, and the establishment produces a turkey product with a different formulation, the establishment should not use the study alone as its scientific support. In order to support the safety of its process, it would need to use a different study, perform its own study, or use another form of scientific support. Likewise, if an establishment uses a process such as drying for 10 days, and the study shows that drying for 20 days is effective, it would not be appropriate for the establishment to use the study, alone, as scientific support. The establishment would need to provide other support demonstrating that 10 days would be effective in controlling L<sub>m</sub> and other pathogens in their particular product type.

3. Challenge or Inoculated-Pack Studies

In the absence of a published processing guideline, published peer-reviewed paper, or predictive microbial-modeling program that would contain information needed for validation, unpublished studies may be used. In order for an unpublished paper to provide sufficient support, the study would need to be well designed, and the results would need to demonstrate that the specific level of application on specified products or range of products is effective to produce a safe product. For more information on design of challenge studies see the article "Parameters for Determining Inoculated Pack\Challenge Study Protocols" published by the National Advisory Committee on Microbiological Criteria for Foods in the Journal of Food Protection in 2010.," "FSIS Listeria Guideline January 2014 59 Examples of the effects of a post-lethality treatment and an antimicrobial process or treatment over time are shown in Figures 1 and 2, respectively: A challenge study is a study that documents the adequacy of control measures in a process. This involves inoculating the target organism (e.g., L<sub>m</sub> or an appropriate surrogate organism) into a product to determine the effect of control measures such as post-lethality treatment or antimicrobial agent or process on the reduction or growth of the organism. Challenge studies should be conducted by a microbiologist trained in performing challenge studies, in a laboratory to avoid the possible spread of contamination in an establishment. The number of organisms 0 1 2 3 4 5 6 0 4 8 12 16 20 24 28 32 36 40 44 48 Log CFU/gm Time (Hours)

Fig. 1: Effects of a Post Lethality Treatment (PLT) on Levels of Listeria monocytogenes (log CFU/gm) in an RTE Product Over Time Log CFU/gm 0 1 2 3 4 5 6 7 8 9 0 20 40 60 80 100 Log CFU/gm Storage Time, Days

Fig. 2: Listeria monocytogenes Counts for Antimicrobial Treatments 1 & 2 Treatment 1 Treatment 2 Control Note: For Treatment 1, shelf life is 80 days For Treatment 2, shelf life is 50 days", "FSIS Listeria Guideline January 2014 60 before and after the application of the control measure is counted to determine the effect of the control measure. The study determines the effect using different processing variables such as time, temperature, pressure, concentration, acidity, pH and others. Challenge studies are performed under laboratory conditions, which means that the scale of the study is adjusted, based on the capacity of the laboratory (i.e., fewer products may be tested, and a water bath may be used rather than a hotwater pasteurizer). The challenge study is often the most definitive means of scientific support. The study should be done on the same product or very

similarly formulated product, closely replicating conditions in the real production environment.

\u2022 For an antimicrobial agent or treatment, the challenge study should be designed to demonstrate that Listeria growth does not occur over the product shelf life. (see establishing a Product\u2019s Shelf-life below). \u2022 For a PLT, the challenge study should demonstrate a specific log reduction of Listeria effective from day 0 to the point before the product leaves the establishment. If challenge studies are used as supporting documentation by the establishment, it is important that they use product that has similar physical characteristics to that being produced by the establishment (i.e., pH, Aw, etc.) and processing (and intervention) steps that are similar to those utilized by the establishment. For example: \u2022 If a challenge study examines the effect of steam pasteurization or hot-water pasteurization, the time and temperature of treatment may be critical components of the study. In order for the study to be used as supporting documentation, the establishment would need to apply the same or similar time and temperature treatment. \u2022 For high pressure pasteurization, pressure is a critical variable. The establishment would need to apply the same pressure as specified in the study.

\u2022 For the use of chemical additives as antimicrobial agents, pH, acidity, and concentration may be additional critical variables. The establishment would need to demonstrate that they are applying the same levels as specified in the study. All challenge studies should be based on a sound statistical design and should also employ positive and negative controls. Listeria innocua strains are usually employed as a nonpathogenic surrogate for Lm. The inoculum level should be at least two logs greater (if possible) than the log reduction to be demonstrated. The inoculum should be composed of a cocktail of 3-5 Listeria strains, including some strains known to be relatively resistant to the Question: Many dried meat products do not support the growth of Lm, and Lm present on the product will die. If challenge studies are conducted to demonstrate the death of some identified amount of Lm, will FSIS consider the products to fall under Alt. 1? Answer: When challenge or inoculation studies incorporated into the establishment\u2019s HACCP plan demonstrate both elimination of Lm before product leaves the establishment and that Lm growth is not supported during the shelf life, those products likely will fall under Alt. 1.", "FSIS Listeria Guideline January 2014 61 treatment. The levels of Listeria should be measured at day 0 (initial level) and remaining levels measured daily or at regular intervals (Day 1, 2, 3) to the end of the shelf life (or until the point when product would leave the establishment). Listeria isolates used in challenge studies should relate to the type of meat or poultry product. They could be from foodborne illness outbreaks or from meat or poultry processing environments. If possible, one of the strains should be from a product as similar as possible to the product to be challenged, e.g., a strain isolated from a specific luncheon meat should be included in challenge studies for luncheon meats. A single strain of L. innocua may be used if the strain is known to be particularly resistant to the treatment (~2 fold more resistant) being tested (e.g., L. innocua M1 for studies evaluating heat treatments). One way of obtaining isolates is to purchase strains from culture repositories. These include the American Type Culture Collection (ATCC), the National Collection of Type Cultures (NCTC). Cornell University hosts the ILSI Lm strains collection, which provides researchers with a standard set of Lm isolates, thus allowing for comparison of data on Listeria physiological and genetic characteristics generated in different laboratories. These isolates are grouped into two separate sets, including one diversity subset (25 isolates) and one matched human and food isolate subset (17 isolates, 2 of which are also included in the diversity subset) representing

isolates from human listeriosis outbreaks and cases. More information on the ILSI Listeria strain collection, including a list of all isolates in the collection, source information, year of isolation, serotype, and ribotype information is available on Dr. Wiedmann's website at:

<http://foodscience.cornell.edu/cals/foodsci/research/labs/wiedmann/ilsi-na-strain.cfm>.

4. Validated Predictive Microbial-Modeling Programs Establishments may use the results of modeling programs to satisfy the first part of validation, scientific support. If the establishment: \u2022 Inputs accurate values into the modeling program, and \u2022 The modeling program has been validated for the type of product in question, and \u2022 The results of the modeling program show adequate control of Lm, then the establishment does not need additional scientific support such as a challenge study. If the pathogen modeling program was developed from the manufacturer of an antimicrobial agent, the establishment can contact the manufacturer to determine whether the model has been validated for their particular product and process. The following are some key points regarding the use of microbial pathogen modeling programs: \u2022 Modeling programs can be obtained from published studies or from the manufacturer of an antimicrobial agent. Information and guidance on the application of the antimicrobial agent may be obtained from the manufacturer. \u2022 Establishments can also seek guidance from University Extension Service specialists or authors of the modeling programs on how to use a modeling program. \u2022 If using a modeling program to determine the amount of antimicrobial agent to use, follow the directions with regards to salt content, moisture level of the finished products, and other information needed. For example, a modeling program may ask to confirm that the product is a cured product because the model is only valid for cured products. It will", "FSIS Listeria Guideline January 2014 62 ask for the following: Shelf life of product in days, product specification, salt content (%) and finished product moisture content (%). The program will calculate the amount of lactate\diacetate to be used and the log suppression of Lm based on the information provided. \u2022 Growth models on the use of antimicrobial agents are available mostly for cured products. For uncured products where there are no growth models, validation studies need to be conducted per product. \u2022 Verify the effectiveness of the antimicrobial agent\process used by testing for Lm growth during the shelf life of the product, at a certain frequency. \u2022 Maintain and monitor records of validation, verification, and corrective actions for deviations from the effective application of antimicrobial agents\processes.

5. Establishing the Shelf-life of the Product As stated in Section 2.2, the AMAP must be effective throughout the shelf life of the product (9 CFR 430.1). The shelf life of the product is defined as the amount of time the product can be stored under specified conditions and still remain safe with acceptable quality. In order to demonstrate effectiveness of control measures over the shelf life of the product, the establishment would need to establish their expected shelf life through a challenge study, shelflife study, or other supporting documentation such as predictive microbial modeling. This study or other supporting documentation should demonstrate that the AMAP is effective in controlling growth over the product's shelf life. Although establishments are not required to label their product with a use-by date, or other information indicating the shelf life of the product, a prudent establishment would use this labeling to help ensure that the product is not consumed after the shelf life is complete. An establishment may perform the shelf-life study or provide other supporting documentation establishing the shelf life of the product. A microbial shelf-life study is one that measures the increase or decrease in

the number of the target organism or pathogen during storage. For an AMAP, a shelf-life study is important to perform as part of the challenge study, because it determines the time (in days) the growth of Lm is controlled. Both refrigeration temperatures (e.g., 40°F) and a slightly abusive temperature (e.g., 45°F) should be used in the shelf-life study in order to ensure that if Lm is present and viable, growth will occur and can be measured throughout shelf life. This slightly abusive temperature also represents the worse-case conditions that could occur during cold-chain storage and handling. Some of the factors that should be considered in the shelf life study of a product with an added AMAP to determine that the agent or process is effective in limiting or suppressing growth of Lm are: 1. Suppression of Lm growth in product during shelf life growth should be lower in the product with added antimicrobial than growth in the untreated control. Although the Compliance Guidelines set a maximum of less than 2 log growth of Lm during the shelf life of product with added antimicrobials for the purposes of the challenge study, it is best to target a lower amount of growth than this. 2. The rate of growth of Lm in product-- the Lm growth-rate in product with added antimicrobial should be slower than the growth rate in product without added antimicrobial.", "FSIS Listeria Guideline January 2014 63 3. Temperature for holding product during the shelf life study Most studies use the temperature that the product is normally held during storage as the temperature during shelf life studies e.g., refrigerated temperature of 38-40 °F. Shelf life studies can also use or include a temperature of 45 °F to hold product since this reflects consumer handling. A resource article for conducting challenge studies for validation of antimicrobial agents is the Considerations for Establishing Safety-based Consume-by Date Labels for Refrigerated Ready-to-eat Foods(NACMCF, 2004).This article gives guidance on how to determine the shelf-life of a RTE product containing an added antimicrobial agent that is supposed to suppress Lm growth during the refrigerated shelf-life. Most studies use the temperature which the product is normally held during storage as the temperature during shelf life studies, e.g., refrigerated temperature of 38-40°F. As described above, shelf-life studies also should use or include a temperature of 45°F which reflects consumer handling. The NACMCF document recommended to using a higher temperature for shelf-life studies because foods can encounter a range of temperatures below and above 45°F, with higher temperatures more likely in grocery store cases and during consumer handling. Therefore these temperatures more accurately reflect reality. In addition, establishments should extend the time period of their study (e.g., 2.5 times the shelf-life) to determine the safety if consumers hold the product longer. NOTE: A product with an added antimicrobial agent demonstrating Lm growth of <2 log at a storage temperature of 38-40°F and at 45°F or above would be viewed by FSIS as more protective of public health than another product showing the same growth only when stored at 38-40°F.

III. In-Plant Demonstration Data The second element of HACCP systems validation is initial in-plant validation which may include in-plant observations, measurements, microbiological test results, or other information demonstrating that the Lm control measures, as written into a HACCP system, can be executed within a particular establishment to achieve the process intended result. In cases where the process specifications described in the supporting documentation are implemented in the same or similar enough way (see box below) in the establishment process, and when the scientific supporting documentation used contains microbiological data specifying the level of pathogen reduction achieved by the

intervention strategy for the target pathogen identified in the hazard analysis, the establishment should: \u2022 Identify the critical operating parameters in the scientific support, AND \u2022 Translate them in the HACCP system, AND As of the date of this guideline, FSIS realizes that some establishments may not have kept their initial in-plant demonstration documents from when HACCP was originally implemented. Those establishments that have not will be allowed the time to assemble their in-plant demonstration documents. The Agency will describe and explain these documents in a future Federal Register Notice that it intends to issue when it finalizes the Compliance Guideline on HACCP systems validation. Until the Federal Register Notice issues and further instructions are given to FSIS personnel, FSIS will not cite the lack of in-plant validation data as the only reason for the documentation of noncompliance.", "FSIS Listeria Guideline January 2014 64 \u2022 Demonstrate that the critical operating parameters are being met by gathering 90 days of execution data. By demonstrating that the critical operating parameters are being met through the collection of execution data, the establishment will have addressed the second element of validation \u2013 inplant demonstration data without the need for further microbiological data. In cases where the process specifications described in the supporting documentation are not implemented in the same or similar enough way in the establishment\u2019s process, or when the scientific supporting documentation used does not contain microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, the establishment should: \u2022 Validate that the intervention as modified actually achieves the effect documented in the scientific supporting documentation (Element 1), AND \u2022 Validate that the modified critical operating parameters are being met, AND \u2022 Validate the intervention\u2019s effectiveness under actual in-plant conditions. The establishment should develop the appropriate execution data during the initial 90 days of implementing a new HACCP system, or whenever a new or modified food safety hazard control is introduced into an existing HACCP system as identified during a reassessment. During these 90 calendar days, an establishment gathers the necessary execution data to demonstrate critical operating parameters are being achieved. In essence, the establishment would repeatedly test the adequacy of the process steps in the HACCP system to establish that the HACCP system meets the designed parameters and achieves the intended result as described in the HACCP Final Rule. These execution data become part of the validation supporting documentation along with the scientific support used to design the HACCP system.

NOTE: Microbiological data (e.g., challenge studies or in-plant data) is encouraged but not required to comply with the minimum initial validation requirements provided the establishment has adequate scientific supporting documentation (e.g., journal articles) to meet the first element of validation. In addition the establishment would need to follow the parameters in the scientific support, and demonstrate that it can meet the critical parameters during operation (the second element of validation). In order to meet the second element of validation (in-plant demonstration data) the establishment would need to gather data (such as monitoring records of water temperature for a hot water pasteurization process or of water activity resulting from a drying process) over the initial 90 days demonstrating the critical operational parameters are being achieved. Generally, establishments should use the same critical operational parameters as those in the support documents. In some circumstances, establishments may be able to support using critical operational parameters that are different

from those in the support documents (e.g., higher concentrations of antimicrobials or higher thermal processing temperatures). In these cases, establishments should provide justification supporting that the levels chosen are at least as effective as those in the support documents. In addition to ensuring that the levels chosen are at least equally as effective, establishments should also ensure the levels are also safe and suitable per FSIS Directive 7120.1.","FSIS Listeria Guideline January 2014 65 For examples of the type of scientific support and in-plant demonstration data that would be expected for different types of Lm controls, please see the validation examples taken from the FSIS Compliance Guideline on HACCP Systems Validation on the following pages.","FSIS Listeria Guideline January 2014 66 IV. Validation Examples NOTE: Establishments may also collect environmental swab samples on different processing dates and at different times during the 90-day initial validation period to potentially find hard-to-control areas and niches within the establishment. In plant monitoring records for 90 day period in which temperature of water is mapped and measured at increased frequencies to support monitoring procedures and

frequencies.", "FSIS Listeria Guideline January 2014 68 Appendix 2.2: Sanitation I. Introduction II. Pre Operational Sanitation Procedures III. Operational Sanitation Procedures 1. Controlling Temperature and Air Handling Units 2. Equipment Design 3. Traffic Control 4. Employee Hygiene 5. Controlling Cross Contamination IV. Sanitation During Construction V. Intensified Sanitation in Response to Positives VI. Determining the Effectiveness of the Sanitation Program I. Introduction The cornerstone of the Listeria Rule is sanitation within the post-lethality environment. All other layers of antimicrobial interventions (antimicrobial agents, post-lethality treatments, antimicrobial processes) are built upon the effective design of the establishment's sanitation program to control Lm and will not be effective if the sanitation program is poorly designed. Understanding the growth/survival characteristics is critical to the success of controlling the pathogen. Lm is more heat-resistant than most foodborne pathogens. It can survive freezing and drying. Lm resists high salt levels, nitrite, and acid and can grow in vacuum packaged products. Most importantly, the pathogen can grow in a damp, cool environment. Once the bacteria attaches to a surface it can form a biofilm and establish a niche, or harborage site, which can become more resistant to superficial cleaning regimens. Bacteria can then spread from the niches to food-contact surfaces and product. The critical components of an effective sanitation program to control Lm can be divided into the following major categories. These include: Pre-operational cleaning and sanitizing procedures that are effective in preventing Lm from forming niches or harborage sites in the processing environment. Operational sanitation procedures to prevent cross-contamination in the RTE processing environment. Intensified cleaning and sanitizing procedures in response to positive sampling results. Documentation and verification of cleaning and sanitizing procedures. Establishments are required to develop and implement the Sanitation SOP regulatory requirements, 9 CFR 416.12 through 416.16. Proper and effective sanitation involves both cleaning and sanitizing, and verifying that the cleaning and sanitizing were effective. This involves developing and implementing written sanitation standard operating procedures (Sanitation SOPs). Sanitation SOPs could be viewed as the first step to designing a total system, including the HACCP plan that will prevent, eliminate, or reduce the likelihood of pathogenic bacteria from entering and harboring in the plant environment.", "FSIS Listeria Guideline January 2014 69 Sources, Harborage, and Control of Lm Contamination An effective sanitation program should prevent contamination of food contact surfaces and prevent the formation and growth of Lm in a niche, especially in areas where the product is post-lethality exposed. A niche is an area where Listeria has grown to high numbers, such as a harborage site within the plant. Harborage sites provide an ideal place for Lm to establish and multiply. Factors that may affect the formation of niches include: equipment design, construction activities, operational conditions that move product debris into difficult to clean locations, mid-shift cleanup, high pressure during cleaning, and product characteristics that require excessive rinsing. Certain strains can become established in a processing environment for months or years. Lm can be spread from these sites and re-contaminate food or food contact surfaces between the lethality step and packaging. Therefore, the sanitation procedures should target the known reservoirs and harborage sites within the RTE processing environment. Examples of reservoirs and harborage sites of Lm in RTE processing environment Drains, hollow rollers on conveyors, on-off valves and switches, worn or cracked rubber seals around doors, vacuum/air pressure pumps, lines,

cracked tubular rods on equipment, air filters, condensate from refrigeration units, floors, standing water, open or gulley drains, ceilings and over head pipes, overhead rails and trolleys, chiller and passageway walls and doors, chiller shelving, roller guards, door handles, boots, ice makers, saturated insulation (wet or moldy), trolley and forklifts, compressed air, in-line air filters, trash cans, cracked hoses, wet, rusting or hollow framework, walls that are cracked, pitted, or covered with inadequately sealed surface panels, maintenance and cleaning tools, space between close fitting metal-to-plastic parts, and space between close fitting metal-to-metal parts. \u2022 Filling or packaging equipment, packaging film or wrappers, solutions (e.g., brine) used in chilling food, \u2022 Peelers, slicers, shredders, blenders, brine chillers, casing removal system, scales, or other equipment used after heating and before packaging, Spiral or blast freezers, conveyors, \u2022 Bins, tubs, wagons, totes, or other containers used to hold exposed product.

II. Pre-operational Cleaning and Sanitation Procedures

Typically, effective sanitation can be distilled down to the nine following steps. This is an example outline. Cleaning should be intensified during periods of construction and if repetitive positives are found.", "FSIS Listeria Guideline January 2014 70

- 1) Perform dry cleaning of the equipment, floors, conveyor belts, and tables to remove meat particles and other solid debris. Some equipment, such as slicers and dicers, will require disassembly so that parts can be cleaned thoroughly.
- 2) Wash and rinse floor.
- 3) Pre-rinse equipment (rinse in same direction as product flow). Pre-rinse with warm or cold water \u2013 less than 140\u00b0F (hot water may coagulate proteins or \u201cset soils\u201d).
- 4) Clean, foam, and scrub equipment. Always use at least the minimum contact time for the detergent\foam. Guidance should be provided concerning the location of possible niches and written instructions provided concerning the cleaning method. NOTE: Live steam for cleaning is not acceptable at this step since it may bake organic matter on the equipment.
- 5) Rinse equipment (rinse in same direction as product flow).
- 6) Visually inspect equipment to identify minute pieces of meat and biological residues.
- 7) Sanitize floor and then equipment to avoid contaminating equipment with aerosols from floor cleaning. Care should be taken in using high pressure hoses in cleaning the floor so that water won\u2019t splash on the already cleaned equipment. Use hot water, at least 180\u00b0F, for about 10 seconds to sanitize equipment. Sanitizers (e.g., acidic quaternary ammonia) may be more effective than steam for Lm control.
- 8) Rotate sanitizers periodically. Alternating between alkaline-based and acid-based detergents helps to avoid \u201csoapstone\u201d and biofilms. This also helps change the pH to prevent adaptation of bacteria to a particular environment. Portable highpressure, low volume cleaning equipment (131\u00b0F (55\u00b0C) with 20-85 kg/cm<sup>2</sup> pressure and 6- 16 liters\minute) can also be used.
- 9) Dry. Removing excess moisture can be done most safely and efficiently by air drying. Reduced relative humidity can speed the process. Avoid any possible crosscontamination from aerosol or splash if a method other than air drying (e.g., using a squeegee or towel) is used.

Recommended Frequencies for Cleaning and Sanitizing Procedures

Area Recommended Cleaning Frequency

All processing equipment, floors and drains, waste containers, totes, wagons, RTE storage areas Daily

Walls, condensation drips pans, RTE coolers Weekly

Freezers Semi-annually", "FSIS Listeria Guideline January 2014 71

Sanitizers

Cleaning and sanitizing are vital to any effective sanitation program. Thorough cleaning should be followed by sanitizing. Generally, the cleaning step is to remove all waste materials and soils, and the sanitizing step is to destroy all microorganisms. Careful consideration should be given to selecting both cleaning and sanitizing solutions. It is important

to use solutions that are compatible with the equipment materials, such as stainless steel or heavy plastics, and solutions that are effective in destroying the type of bacteria commonly associated with the type of products produced in the establishment. Rather than relying on a single sanitizer, rotating sanitizers will help prevent the development of microorganisms resistant to a particular sanitizer. The concentration and application processes for all sanitizers approved for use in meat and poultry establishments are referenced in Title 21 Code of Federal Regulations (21 CFR), Part 178, section 178.1010. All cleaners and sanitizers commercially available should have, at the minimum, the following information either on the label or available on a specification sheet that must accompany the product: Product Description \u2022 \*\* Instructions on how to use the product (concentration, method of application, contact time, temperature) \u2022 Properties \u2022 Safety Information Additional information that is sometimes available includes: \u2022 Benefits \u2022 Quality Assurance Statements \*\*Effectiveness against Listeria. Some manufacturers provide labeling in both English and Spanish, which makes the products more user friendly in various environments. At least one manufacturer also has commercially available color coded products that are easy to associate with a particular cleaning or sanitizing task. Recommendations for sanitizers inactivating Lm in biofilms on stainless and plastic conveyor belts: \u2022 Chlorine and iodophors are not effective inactivating Lm in biofilms on stainless steel. \u2022 The most effective sanitizers are acidic (not neutral) quaternary ammonium compounds, peracetic acid, and chlorine dioxide. \u2022 The less effective are the mixed halogens and acid anionics sanitizers, which were less effective than the sanitizers listed in the 2nd bullet above. \u2022 And the least effective sanitizers were chlorine, iodophors, and neutral quaternary ammonium compounds.", "FSIS Listeria Guideline January 2014 72 III. Operational Sanitation Procedures to Prevent Cross Contamination Between Raw and RTE Post-Lethality Environment 1. Controlling Temperature and air handling units \u2022 Maintain temperature in processing areas and packaging rooms as stated in the HACCP plan, Sanitation SOPs, or Prerequisite Programs. \u2022 Maintain cold temperature (<50\u00ba F) in packaging room for products that are to be refrigerated or frozen, as stated in the HACCP plan, Sanitation SOPs, or Prerequisite Programs to prevent Lm growth in the RTE processing environment. \u2022 Monitor temperatures as stated in the HACCP plan, Sanitation SOPs, or Prerequisite Programs. \u2022 Establish positive air pressure movement out of the RTE room into the raw processing areas. \u2022 Clean cooling units and air handling units at some specific frequency. \u2022 Immediately address and correct problems of dripping condensation and standing water. Production of RTE products should be stopped during repairs and corrective actions for these problems. The equipment and processing area should be cleaned and sanitized after all the repairs and corrective actions are finished. 2. Equipment Design \u2022 Evaluate the equipment to ensure that it can be easily dismantled for cleaning and is durable. \u2022 Investigate for potential Lm harborage sites, such as hollow rollers. \u2022 If new equipment is purchased, select equipment designed to enhance cleaning \u2022 All areas and parts should be accessible for manual cleaning and inspection or be readily disassembled. \u2022 Closed conveyor designs are more difficult to clean. Equipment on the processing line should be as easy to clean as possible. \u2022 Avoid hollow conveyor rollers and hollow framing. If hollow material is used, have a continuous weld seal instead of caulk. \u2022 Select food contact surfaces that are inert, smooth, and non-porous. \u2022 Equipment should be self-draining or self-emptying. \u2022 Maintain

equipment and machinery by adopting a regular preventive maintenance schedule (QA should verify performance)", "FSIS Listeria Guideline January 2014 73 \u2022 Damaged, pitted, corroded, and cracked equipment should be repaired or replaced. \u2022 Repair parts or machinery in a manner that prevents food deposits that are not easily removed with normal cleaning. \u2022 Use separate tools for RTE equipment only. Sanitize them before and after each use. \u2022 If compressed air is used, maintain and replace in-line filters regularly. \u2022 Use lubricants that contain listericidal additives, such as sodium benzoate. Lm can grow in lubricants that are contaminated with food particles. \u2022 Clean maintenance tools (including wrenches, screws, and tool boxes) on a regular basis. Consider designating certain tools for raw and RTE areas.

3. Traffic Control One critical component of an effective sanitation program is control of the movement of personnel and raw product to prevent cross-contamination of RTE finished product and FCSs within the post-lethality environment. Establishments should examine product routes from heat treatment or other antimicrobial control steps to eliminate Lm, to final packaging. The following are steps that can be used to develop control procedures. Establish traffic patterns to eliminate movement of personnel, meat containers, meat, ingredients, pallets, and refuse containers between raw and finished product areas. If possible, employees should not work in both raw and RTE areas. If they must work in both areas, they must change outer and other soiled clothing, wash and sanitize hands, and clean and sanitize footwear. \u2022 If possible, use air locks or vestibules between raw and RTE areas. \u2022 Use foam sanitizing spray systems on either side of the RTE room door on a timed system or triggered by entry\exit. \u2022 Clean, dry floors are preferable to foot baths at the point of entry because effective concentrations of disinfectant are difficult to maintain and may become a source of contamination. \u2022 If foot baths are absolutely necessary: \u2022 Wear rubber or other non-porous boots. \u2022 Maintain them properly, so that they are clean and maintain effective levels of sanitizer. \u2022 Solutions should contain stronger concentrations of sanitizer than normally used on equipment (e.g., 200 ppm iodophor, 400-800 ppm quaternary ammonia compound). \u2022 Use a minimum depth of 2 inches.", "FSIS Listeria Guideline January 2014 74 NOTE: Chlorine is NOT recommended for foot baths because of rapid inactivation, especially if cleated boots are used. The accumulation of biological material adhering to the cleats inactivates (or reduces) the bioavailability of chlorine, making it less effective. Monitor and maintain the strength of the chlorine solution, if used.

4. Employee Hygiene Development of employee hygiene procedures to prevent the contamination of FCSs should be the responsibility of management. The employee should be responsible for preventing contamination of food products and the management should be responsible for ensuring that the employee is properly trained and maintains good practices. \u2022 Employee responsibilities and actions should include:

- \u2022 Using a 20 second hand wash, allowing the soap suds to be in contact with the hands for this period of time, after using restroom facilities.
- \u2022 Washing hands before entering the work area, when leaving work area, and before handling product.
- \u2022 If gloves are worn: \u2022 Gloves that handle RTE product should be disposable. \u2022 Dispose immediately and replace if anything other than product and FCS is touched. \u2022 Dispose of gloves when leaving the processing line. \u2022 Remove coats, gloves, sleeves and other outer clothing when leaving RTE areas. \u2022 Do not wear coats, gloves, sleeves or other outer clothing inside restrooms or cafeterias. \u2022 Do not store soiled garments in lockers. \u2022 Do not eat in the locker room or store food in lockers

because food may attract insects and vermin. \u2022 Do not store operator hand tools in personal lockers. This equipment must remain in the RTE area at all times. \u2022 Do not allow employees who clean utensils and equipment for raw materials to clean RTE utensils and equipment, if possible. \u2022 The tools to clean utensils and equipment for raw materials must be different than those used to clean RTE utensils and equipment. In either case, the intent is to prevent cross contamination of finished product. \u2022 Management responsibilities should include:" "FSIS Listeria Guideline January 2014 75 \u2022 Providing hand washing facilities at proper locations. \u2022 Ensuring that the employee receives proper hygiene instruction before starting \u2013 use of hand soaps and sanitizers, no-touch dispensing systems, and boot and doorway sanitizing systems. \u2022 Developing a system for monitoring employee hygiene practices. \u2022 Developing a system for tracking the training, testing, and certification. \u2022 Retraining employees before placing them back into production if they are absent from the job or have failed to follow acceptable hygiene practices. This will help ensure that the employees are following current, acceptable hygiene habits. \u2022 Do not permit maintenance employees in RTE areas during operations if possible, primarily because they may cause direct product contamination or adulteration if they touch or lay their \u201cdirty\u201d equipment hands onto food contact surfaces. If this is not possible: \u2022 Consider the need to cease operations until a full cleaning and sanitizing is done, or, \u2022 Require maintenance personnel to change outer clothing and any other soiled clothing, use separate tools for raw and RTE areas (or wash and sanitize tools and hands prior to entering RTE areas) and wear only freshly cleaned\sanitized footwear in such areas. \u2022 Use separate equipment, maintenance tools and utensils for the RTE and raw areas. If not possible, there should be a time separation between raw processing\handling and RTE processing in order prevent cross contamination of finished product.

5. Controlling Cross Contamination

\u2022 For establishments processing RTE products, establish procedures to ensure that other non-meat or non-poultry RTE ingredients do not cause cross-contamination with Listeria.

\u2022 Maintain an effective rodent and insect infestation preventive and Control Program.

Rats, mice, and insects are sources of Listeria and other microbial contamination. \u2022 Eliminate standing water which can facilitate the spread of Lm into other areas of the plant. Sanitizer boluses can be used to sanitize standing water on a continuing basis. \u2022 Discard products that touch environmental surfaces, such as products falling on the floor, if the product cannot be properly re-conditioned (e.g., by washing). \u2022 Pallets can serve as a source of cross-contamination \u2013 pallets for raw materials should not be used in RTE areas or used for finished product. \u2022 Do not allow condensation to build up or drip over exposed RTE product." "FSIS Listeria Guideline January 2014 76 \u2022 Do not spray high pressure hoses near exposed product. Aerosols could develop that could contaminate the product. \u2022 Do not allow employees to store knives, gloves, or equipment in their lockers. Provide designated storage areas for these items. \u2022 Employees should not wear gloves, coats, or aprons in the restroom or break areas. \u2022 Drains from the \u201cdirty\u201d or \u201craw\u201d side should not be connected to those on the \u201cclean\u201d or \u201ccooked\u201d side.

Dual Jurisdiction Establishments Because FSIS-regulated products are susceptible to Lm outgrowth: It is advisable, due to the food safety nature of FSIS-regulated product, to separate processing areas for FSIS-regulated products and FDA-regulated products by time or space, such as scheduling processing on different days. If that is not possible, schedule FSIS product

processing first, then FDA product processing. If FDA product is produced first, a complete clean-up and sanitizing before starting FSIS product processing is recommended. Because of the risk for cross contamination, consider assigning different personnel for FSIS and FDA products and processing areas, if possible, especially if both are conducted on the same day. If not possible, have personnel clean hands thoroughly, and use unused, clean coats, new gloves and hairnets, and sanitized boots for FSIS and FDA processing.

**IV. Sanitation During Construction**

Dust generated by construction activities can move throughout the plant on air currents or be transferred by people or equipment traveling through the construction area into other areas of the establishment. A study by De Roin et al., (2003) showed that Lm in dust can survive and grow, once in contact with meat surfaces. Construction or maintenance activities that can result in Lm contamination of RTE product of FCS include removal of drains, removal of floor coatings, removal of a wall or ceiling that has absorbed moisture, movement of potentially contaminated materials through RTE areas or areas that directly connect with RTE processing areas, and exposure of areas typically not accessible for cleaning. Tompkin (2002) considers the potential of introduction of Lm into the RTE processing environment from an outside source or through disturbance of a harborage site (e.g., the process of replacing floor drains, walls, or cooling units) as a great concern.

**Control of the Environment during Construction**

If possible, suspend operations during construction. Otherwise:

- \u2022 Dust from construction can be difficult to detect and control. Therefore, increased monitoring of product, food-contact surfaces, and the environment is recommended during and after these disruptive events.
- \u2022 Establish negative air pressure in the construction area in order to ensure that air does not flow from the construction area into the plant.", "FSIS Listeria Guideline January 2014 77

- \u2022 Temporary partitions can be established to protect the undisturbed areas of the plant from construction dust and debris.
- \u2022 Cover any construction debris when moving out of the construction area.
- \u2022 Do not move debris through RTE processing areas or areas that directly connect to RTE processing areas, if possible.
- \u2022 Schedule construction during non-processing hours.
- \u2022 Conduct intensified cleaning and monitoring of food contact and environmental surfaces after construction is complete.
- Control of the Environment after Construction**
- \u2022 Schedule removal of all construction equipment, barriers, and final debris after production hours.
- \u2022 Perform a thorough clean-up and increased sanitation sampling at pre-operational inspection.
- Continue intensified cleaning and monitoring of food contact and environmental surfaces until food contact surfaces test negative for 3 consecutive days.", "FSIS Listeria Guideline January 2014 78

**V. Intensified Cleaning and Sanitation Following a Positive Listeria Sample**

The following are actions that can be taken during intensified cleaning. Not all steps may be necessary to address contamination. Actions should be escalated to address consecutive positives. If positives occur, consider:

- \u2022 Thoroughly cleaning and scrubbing sites where positives were found.
- \u2022 Identifying all possible harborage sites and cross contamination pathways.
- Clean and sanitize harborage points and address cross contamination.
- \u2022 Removing equipment parts and soaking overnight.
- \u2022 Increasing the frequency of all less than daily sanitation procedures (e.g., walls and ceilings).
- \u2022 Scrubbing surfaces where product residue accumulates. Pay special attention to gaps, cracks, rough welds, and crevices in equipment.
- If positives continue to occur, consider:
- \u2022 Disassembling equipment and soaking of parts in quaternary ammonia overnight.
- \u2022 After cleaning and sanitizing of larger pieces of equipment, applying steam heat via an oven at 160\u2070F and

holding for 20-30 minutes. Fogging the room with a sanitizer solution. Replacing rusty, pitted, peeling tools or parts of equipment with new, smoothsurfaced ones. These rusty, pitted tools and equipment parts serve as ideal harborage places for Lm to grow and multiply. If positives still continue to occur, consider: Identifying harborage points in equipment, such as spiral freezers and slicers, and repairing or replacing. Thoroughly cleaning all areas of the establishment, including raw and non postlethality exposed areas, to address possible harborage sites leading to contamination of RTE areas. Repairing or replacing leaky roofs, broken and cracked equipment, floors, overhead pipes, and cooling units, fans, doors, and windows. Suspend operations during repairs or replacement. FSIS recommends testing the environment for Listeria spp. after repairs are finished. Constructing new walls to separate raw and RTE areas. If drains or air handling units lead to raw areas or outside, consider rerouting.", "FSIS Listeria Guideline January 2014 79 VI. Determining the Effectiveness of the Sanitation Program Establishments can verify the effectiveness of their sanitation program through monitoring the implementation of their pre-operational and operational procedures in their Sanitation SOP. The most basic level of daily verification occurs within the post-lethality environment by monitoring the effective implementation of cleaning\sanitizing of FCSs and observing whether operational sanitation procedures are implemented to prevent cross-contamination (9 CFR 416.13(c)). Maintaining daily records to document the implementation and monitoring of the Sanitation SOP procedures targeted to the RTE environment is also a regulatory requirement to track the effectiveness of the sanitation program (9 CFR 416.16(a)). In addition, observation of employee hygiene practices within the RTE area is required to verify compliance with the Sanitation Performance Standard and prevent cross-contamination (9 CFR 416.5(c)). There are also requirements in the Listeria Rule for sampling for Lm or an indicator organism to verify sanitation. These are discussed in the main body of the Listeria Guideline. It is also important that establishments take steps to prevent future contamination events. This can include reassessing and modifying the Sanitation SOP for specific pieces of equipment or areas of the establishment, increasing cleaning and sanitation frequency, and repairing or replacing equipment or areas of the establishment that may represent harborage sites for Lm. Non-regulatory methods to verify the effectiveness of the Sanitation SOP include the use of total plate counts and ATP bioluminescence, as well as organoleptic inspection. It is important to note that these methods can not be used to replace testing performed for Lm or an indicator organism to meet the requirements of the Listeria Rule. Total Plate Counts (TPC) Visual verification combined with Total Plate Counts (TPCs) can determine both observable contamination and the level of bacterial contamination. Since TPC results are available in about 24 hours, and cannot be obtained at the time of inspection, their value lies in the measurement of the level of contamination. The level of contamination on cleaned and sanitized equipment should be very low (e.g., less than 100 CFU/in<sup>2</sup>). The level of contamination may assist the establishment in determining the source of Listeria contamination and the effectiveness of the Sanitation SOP. Establishments may be able to use the results from TPC monitoring to indicate areas where Listeria spp. testing should be performed. ATP Bioluminescence Testing \u201cLightning\u201d The use of adenosine triphosphate (ATP) bioluminescence swab testing on FCSs can also be a measurement tool to verify sanitary conditions. Most food residue and all microbes are rich in ATP and detecting microorganisms through ATP bioluminescence analysis is one method to test for sanitation

effectiveness. The more ATP present, the greater the amount of bioluminescent light emitted. A microprocessor transforms the data into a digital readout for the luminometer's display and quantifies the light output into a 2 digit zone. The product manufacturer specifies the acceptable and unacceptable zone. The ATP test can detect contamination that is not observable, is a rapid test, and results are available immediately prior to the start of operations. It is important for the establishment to verify that the cleaning and sanitizing procedures are effective. In addition, the recordkeeping should be used for data analysis and the establishment should evaluate the monitoring records for trends. 9 CFR 416.14 requires that each official", "FSIS Listeria Guideline January 2014 80 establishment routinely evaluate the effectiveness of the Sanitation SOP and the procedures therein. Therefore, trend analysis, evaluation, and appropriate revision of the Sanitation SOP, should be conducted, as necessary, to remain effective and current with respect to changes in facilities, operations, equipment, utensils, personnel, and equipment within the post-lethality environment. Records of Sanitation Procedures The following sanitation records are required by 9 CFR 416.16: \u2022 Keep records of the implementation of Sanitation SOPs. \u2022 Maintain monitoring records of Sanitation SOPs. \u2022 Maintain records of corrective actions taken if adulterated product or a direct FCS noncompliance occurs. Ensure appropriate disposition of products, restore sanitary conditions to prevent recurrence, and record the date of the noncompliance and the initials of the plant employee conducting the corrective action. \u2022 Records must be maintained for 6 months, and may be stored electronically. Introduction II. Suggested Training Programs a. Hand washing b. Cross contamination c. Cleaning and sanitizing d. Equipment maintenance e. Sampling f. Facilities III. General Guidance on Training Programs IV. Reference Materials I. Introduction Basic training for all staff should include an overview that defines Lm, the differences between Listeria spp. and Lm, and an explanation of why Lm is a public health concern in post-lethality exposed ready-to-eat products. Training should also include a discussion about locations where Listeria can be found in a processing facility, with an emphasis on common harborage sites. Employees should understand why they should be concerned about Listeria, considering the perspective of both the health of the consumer and the interests of the company. Providing employees with a broad knowledge base regarding Listeria will be beneficial to any Listeria Control Program. For example, the very simple but relevant principle that employees can unknowingly bring Listeria into a ready-to-eat processing facility on their shoes may not be clear to all employees if training does not address that Listeria is ubiquitous in the environment. II. Suggested Training Programs Specific company-wide policies affecting Listeria control should be discussed in a basic training course, such as rules requiring protective smocks of a certain color to be worn in certain areas of the establishment or rules about traffic patterns in the plant. Tailoring your training program to your establishment, your products, and your needs is crucial. a. Hand Washing All personnel should be instructed in proper hand washing techniques. Adopt a descriptive hand washing policy and display clear instructions in all restrooms and at all sinks. Instructions may be for a 20-second hand wash, for example, or to wash hands as long as it

takes to sing "Happy Birthday." A thorough hand washing policy should also include instructions as to when employees should wash their hands, such as after breaks, or before gloving. b. Cross Contamination Although a basic Listeria overview training course for all employees may address cross contamination principles, a more focused cross contamination training course should be directed at employees handling product. Encouraging all employees to be aware and identifying potential harborage sites can limit lost product and reduce risk. Areas for discussion within this course should include the importance of keeping ready-to-eat and raw products separated, from receiving to storage, including food preparation, packaging, and display. General hygiene practices should be discussed, including specific requirements for outer garments, gloves, and", "FSIS Listeria Guideline January 2014 82 shoes. Training should also include common practices that can result in cross contamination, such as an employee sneezing into his or her hand and not washing his or her hands immediately afterwards. The take home message for cross contamination training is that employees must always be aware of how their actions may impact food safety. c. Cleaning and Sanitizing Just as the importance of cleaning and sanitizing cannot be overemphasized, so too is the case for an employee training program that addresses proper cleaning and sanitizing. Employees must not only be shown how to do their job, but they should understand why they are cleaning and sanitizing equipment and utensils and non-food contact surfaces, as well as understand the public health implications of improper cleaning and sanitizing. In addition to the principles of cleaning and sanitizing, the importance of following instructions as to the proper concentration and temperature when preparing chemicals, and the importance of cleaning before sanitizing should also be discussed. Employees need to know specifically what equipment and utensils to sanitize, with special emphasis placed on known harborage sites. The cleaning and sanitation training program should also include a discussion of the importance of disassembling equipment completely when cleaning, as well as instructions as to how often to clean. d. Equipment Maintenance Personnel using equipment and utensils, cleaning and sanitizing equipment and utensils, or involved in the maintenance of equipment and utensils should all be made aware of the importance of a thorough examination for cracks, rust, or pitting which result in non-smooth surfaces. While management may be aware of the importance of looking, for example, for cracks in knives or imperfections in gaskets, the employees that actually handle that equipment may not be aware of these potential Listeria harborage sites. Maintenance personnel should also have training that discusses common improper practices, such as the use of duct tape for equipment repair, which can be a source of contamination and a harborage site for Listeria. e. Sampling Every Listeria control training program should include training targeting personnel involved in the establishment's sampling program. Employees should be thoroughly trained in the "when", "where" and "how" to sample, as well as the "why". For example, the employee should understand that the environmental swabs he or she takes may lead to the identification and elimination of harborage sites. It is also critical that any employee taking samples should be trained in proper aseptic technique procedures. f. Facilities Facilities maintenance personnel should be informed that Listeria thrives in moisture and that it is important that they vigilantly look for leaking roofs, drips, standing water, and condensation. Personnel should be instructed in the procedures to follow if they observe facilities issues that can result in the presence of excessive moisture or water, such as who to notify and what action to take.

III. General Guidance on

Training Programs Training may be delivered in a variety of formats, including handouts, demonstrations, PowerPoint presentations, and on-the-job training, and should be "hands-on whenever", "FSIS Listeria Guideline January 2014 83 possible. It should be delivered in the most appropriate language or languages to meet the needs of its employees so that all employees can fully understand it. For example, training in company sanitation procedures should include a description and demonstration of the procedure to be performed, monitoring procedures, and how to respond to problems. The frequency of training is also very important: all new employees should be trained upon hiring as part of the establishment's new employee orientation prior to starting work. A refresher training course for current employees should be conducted at least once a year to ensure that each employee is properly trained for the job position held. Additional training may be necessary for employees whose duties change. Adequate time for training should be allocated, rather than attempting to fit in training during down time. It is important that all employees clearly understand their roles in the production of safe products upon completion of the training. All aspects of training should be documented, including course contents, who received the training, and when training was given. Even after training is completed, the establishment still maintains the responsibility for ensuring that the training has been implemented correctly. Establishments should verify that employees are implementing the training, as instructed, on the job. This can be accomplished by performing periodic in-house audits where employees are observed to see if they are implementing what they have been trained to do. A review of in-plant records to verify that, for example, equipment has been cleaned at the proper frequency, or that sanitizers have been mixed according to directions, will also indicate if training was effective. The establishment should also have a process in place to address employee training deficiencies, such as retraining. A final suggestion on implementing a successful Listeria training program is to identify a way to get employees involved and vested in the importance of Listeria control and the protection of public health. One way to do this is to have a rewards program where employee incentives, such as a "Food Safety Employee of the Month," are established to recognize outstanding effort in promoting the establishment's overall mission of producing a safe, wholesome product. Opening up Listeria training or the Control Program to employee suggestions may yield some very interesting and useable findings. Employees can be very insightful sources of information for improvements to your Listeria Control Program since they are often able to observe situations that managers do not.

FSIS RTE Sampling Program 3.2 FSIS Sampling Procedure 3.3 Sample Collection and Laboratory  
Testing Methods This chapter provides information on sampling and testing for Lm or an  
indicator organism and design of the Listeria Control Program. It also provides information on  
sampling frequency and other routine sampling. 3.1 Sampling for Lm or an Indicator Organism  
According to the Listeria Rule, establishments in all three alternatives may use verification  
testing for Lm or an indicator organism (e.g., Listeria spp.) to verify sanitation in their  
postlethality processing environment (9 CFR 430.4(c)(1)). Establishments in Alt. 2b and 3 are  
required to test their food contact surfaces (FCS) in order to verify sanitation in the  
environment (9 CFR 430.4(b)(2)(iii)(A) and (3)(i)(A)). Testing FCSs is encouraged for  
establishments in Alt. 1 and Alt. 2a. If a product or FCS tests positive for Lm, then the product  
will be considered adulterated and the product must be reworked or destroyed Establishments  
are required to hold or maintain control of RTE products that FSIS has tested for Lm or RTE  
products that have passed over food contact surfaces that FSIS has tested for Lm.  
Establishments may move such products off-site provided they maintain control of them (e.g.,  
through company seals). 3.2 Design of the Listeria Control Program Establishments may control  
Lm through their HACCP plan, Sanitation SOP, or prerequisite program. Establishments that  
choose to control Lm through their Sanitation SOP or prerequisite program may do so through  
the use of a Listeria Control Program. The Listeria Control Program can be incorporated as part  
of the Sanitation SOP or designed to work with the Sanitation SOP NOTE: A finding of Listeria  
spp. on a FCS indicates conditions where Lm may be present, but the product is not considered  
adulterated. However, establishments are expected to take corrective action, according to their  
control alternative, to address Listeria spp. positives so that product does not become  
adulterated.", "FSIS Listeria Guideline January 2014 86 Question: My establishment tests FCS for  
Listeria spp. and found a positive result. Are we required to further analyze the sample to  
determine if it\u2019s positive for Lm? Answer: No. There is no requirement that  
establishments further analyze Listeria spp. positives on FCS to determine if they are positive  
for Lm. However, the establishment is required to take corrective actions, depending on their  
control alternative (see Chapter 4 for more information), and HACCP plan as a prerequisite  
program. It is expected that the Listeria Control Program will be designed based on the relative  
risk of the product, depending on the alternative. It is also recommended that establishments  
take corrective and preventive actions and perform enhanced sampling in response to positives  
(see Chapter 4). If the establishment chooses to use a prerequisite program for controlling Lm  
in the environment, it must be included as part of the documentation the establishment  
maintains under 9 CFR 417.5 (see 9 CFR 430.4(c)(6)). Establishments may use the results from  
their Listeria Control Program or other prerequisite program as support for the decision in their  
hazard analysis that Lm is not a hazard reasonably likely to occur in their product. The Listeria  
Control Program should be designed to meet the requirements of the Listeria Rule. For  
establishments in Alt. 2b and 3, the Listeria Rule (9 CFR 430.4(b)(2)(iii) and (3)(i)) requires that  
establishments: \u2022 Provide for testing of FCS sites, \u2022 Identify conditions under which

the establishment will hold and test product, \u2022 State the frequency that testing will be done, \u2022 Identify the size and location of the sites that will be sampled, and \u2022 Provide an explanation of why the testing frequency is sufficient to control Lm. In addition, Alt. 3 deli and hotdog processors are required to perform follow-up sampling and hold and test product after a second positive (9 CFR 430.4(b)(3)(ii)(B)). The Listeria Control Program should also include information about the sampling and testing methods that are used to analyze the samples, and actions taken in response to positive test results, including disposition of contaminated product. Also, although not required, if non food-contact surfaces (NFCS) and product samples are collected as part of the establishment\u2019s routine sampling program, they should be described in the Listeria Control Program (Sections 3.3-3.6 and 4.1-4.3). Listeria Control Program Considerations \u2022 Listeria monocytogenes (Lm) is the foodborne pathogenic species of the bacterial genus Listeria. Most establishments choose to test for Listeria spp. (i.e., Genus Listeria) because they are indicators for Lm. \u2022 Establishments are expected to have Routine and Enhanced Sampling Programs. \u2022 Step-by-step sample collection and laboratory methods should be included. \u2022 The establishment should list all of the food contact surface (FCS) samples they will collect as part of their Listeria Control Program. \u2022 The establishment\u2019s Hold and Test program should be included as part of the Listeria Control Program. NOTE: If the establishment does decide to use its Listeria Control Program as a basis for decisions in the hazard analysis, the establishment should follow the project. If the establishment deviates from the project then FSIS may find that the establishment can no longer support its decision that Lm is not reasonably likely to occur in the product. The establishment would need to provide further justification as to why the product is unlikely to be contaminated with Lm." , "FSIS Listeria Guideline January 2014 87 Parts of the Listeria Control Program The following outline provides considerations that should be taken into account by establishments when designing a Listeria Control Program. Establishments are encouraged to include any additional considerations in designing a Listeria Control Program that are unique to its specific process. \uf0fc Types of products produced (HACCP programs considered under the Listeria Control Program). \uf0fc Listeria Control Alternative(s) used for each product. \uf0fc Organism to be sampled (Lm, Listeria spp., or Listeria-like organisms). \uf0fc Routine Sampling Program (Section 3.3). o List of sites that will be sampled (all possible food contact sites should be identified for Alt.2b and 3 establishments, see page 3-5). o Number and frequency of samples collected and explanation for this frequency (Section 3.4). o Size of each site that will be sampled. o Sampling and testing method (Section 3.5). \uf0a7 Step by step collection method. \uf0a7 Type of analysis performed (detailed laboratory analysis methods should be maintained by the lab). o Sampling for non FCS and product (if performed). See Section 3.6. \uf0a7 Number and frequency of samples collected. \uf0a7 Response to positive results. \uf0fc Enhanced Sampling Program (Chapter 4) o Follow-up testing (Section 4.1) \uf0a7 Timeframe for follow-up sampling (e.g., after the 1st FCS positive). \uf0a7 Number of samples collected. \uf0a7 Response to positive results (corrective and preventive actions (details should be included in the establishment\u2019s Sanitation SOP)). o Intensified testing (Section 4.2) \uf0a7 Timeframe for intensified testing (e.g., after the 2nd FCS positive). \uf0a7 Number of samples collected. \uf0a7 Response to positive results. \uf0a7 Intensified sanitation (details should be included in the establishment\u2019s Sanitation SOP). \uf0a7 Number of consecutive negatives to demonstrate that the process is back in control or that sanitary conditions have

been restored. \uf0a7 Conditions for re assessment of the establishment\u2019s HACCP plan in response to positives. \uf0fc Hold and Test Program for product (Section 4.3) o Conditions for hold and test. o Organism to be sampled. o Type of analysis performed. o Number and type of products to be sampled (statistically based program required for Alt. 3 deli and hotdog producers). o Product disposition in case of a positive result. NOTE: Recommended timeframes for performing follow-up sampling and intensified sampling are included in Table 4.1." , "FSIS Listeria Guideline January 2014 88 Question: Would product racks, sticks, and screens that RTE products are cooked on need to be included as product contact surfaces for Listeria sampling? Answer: Yes, the racks, sticks, and screens that are used for RTE product would be considered food contact surfaces, after the product has been cooked. Even though the racks, sticks, and screens are subjected to high temperatures along with the product, they may be handled when being removed from the oven and may be placed in a cooler as the product is cooled, so it is possible they could become contaminated after cooking.

### 3.3 Routine Sampling Program

As part of their Listeria Control Program, establishments are expected to have both routine and enhanced sampling programs. The routine sampling program should include all of the procedures the establishment will follow when collecting routine samples. As part of the routine sampling program, the establishment should identify the sites they will sample, the frequency of sampling, the number of samples they will collect, the size of the sampling sites, the sampling method, and procedures for sampling NFCS and product (if performed).

Establishments should collect samples on first and second shift if RTE post-lethality exposed product is produced on both shifts. In the routine sampling program, establishments can test for Lm or an indicator organism (e.g., Listeria spp.). For more information on testing methods, see Section 3.5. As previously stated, if a product or FCS tests positive for Lm, then the product will be considered adulterated and the product must be reworked or destroyed. A finding of Listeria spp. on a FCS indicates conditions where Lm may be present and grow, but the product is not considered adulterated. There is no requirement that establishments perform a confirmation test on samples that test positive for Listeria spp. to determine if the sample is positive for Lm. However, because many tests for Listeria spp. are screening tests for Lm, a positive result could mean that Lm is present, just not confirmed by the test. Therefore, establishments are expected to take corrective actions and to follow up on Listeria spp. positives according to their control alternative, so that product does not become adulterated.

#### Food Contact Surface (FCS) Sampling

As stated previously, according to the Listeria Rule, establishments in Alt. 2b and 3 are required to provide for testing of FCSs in the post-lethality processing environment to ensure that the surfaces are sanitary and free of Lm or an indicator organism (9 CFR 430.4(b)(2)(iii)(A) and (3)(i)(A)). Establishments are also required to identify the size and location of the sampling sites (9 CFR 430.4(b)(2)(iii)(D) and (3)(i)(D)). FSIS recommends that establishments in Alt. 1 and 2a also test their food contact surfaces. The sites that the establishment will test can be included in the Listeria Control Program. The expectation for establishments in Alt. 2b and 3 is that all possible FCSs in the post-lethality processing area will be identified. This includes surfaces which may come into contact with food on a regular basis as well as those that may come into contact on an intermittent basis. FSIS recommends that the establishment list all possible FCS in their Listeria Control Program. This means that the establishment should identify items that the product touches (e.g., NOTE: The Listeria Rule requires establishments in Alt. 2b or 3 to test their FCS for Lm or an indicator organism. Testing

product alone would not be sufficient to meet the requirements of the Listeria Rule.", "FSIS Listeria Guideline January 2014 89 equipment, utensils, and gloves). For example, it is not necessary to list each individual glove, but \u201cgloves\u201d should be listed as a sampling site. This will assist the establishment in identifying all areas that could harbor bacterial pathogens such as Lm. By including all possible FCS, the establishment could decrease the likelihood that FSIS would find the food safety system inadequate. NOTE: It would not be sufficient for establishments to collect product samples in lieu of food contact surface samples to meet the requirements for Alternative 2b or 3. The Listeria Rule requires establishments to collect food contact surface samples to meet the requirements for those alternatives (9 CFR 430.4(b)(2)(iii)(A) and (b)(3 )(i)(A)). Sample Collection Considerations Establishments should design their sampling programs so that they collect a combination of random and discretionary samples. Initially, samples should be collected at random, to ensure that all FCS have an equal probability of being sampled. Random sampling should be used after an establishment has started production or begins processing a new product to verify that their system is effective. The establishment should have plans in place so that representative samples of all FCS will be sampled over a specified period of time. Once the establishment has generated data demonstrating that their control system is effective, the establishment should adopt a more risk-based sampling program. The risk-based sampling should include discretionary samples that are collected along with the random samples. These samples can be collected at the discretion of the sample collector based on positive results or other conditions as observed at the establishment. For example, if the establishment is collecting 3-5 samples per line as part of the routine sampling program, 1-2 of the samples should be discretionary while the others should be collected randomly. Discretionary samples should be collected if the sample collector observes conditions that could lead to harborage or cross contamination in the postprocessing environment (e.g., backed-up drains, sanitation issues, and condensation dripping over equipment). Establishments should also sample more frequently in areas where sanitation issues have been identified, and use the results of their sanitation monitoring testing (e.g., APC or bioluminescence) to identify sampling sites. Discretionary samples can also be collected to demonstrate the effectiveness of the establishment\u2019s corrective actions. The results from the discretionary samples can be linked to the sample collector\u2019s Question: Each piece of equipment may have multiple sampling sites. Does the establishment need to identify every site it will sample on the equipment, or just identify the piece of equipment as a sampling site? Answer: The establishment just needs to identify the piece of equipment. However, the establishment should recognize that the equipment may have both food contact and non food contact sites, and should sample these according to their Listeria Control Program. Question: An establishment produces both FDA-regulated and USDAregulated product using the same food contact surfaces on different days. Can the establishment collect food contact surface samples as required by the Listeria Rule when FDA product is being produced? Answer: No. Collecting the samples when FDA product is being produced would not meet the requirements of the Listeria Rule, because the surfaces do not come into direct contact with FSIS product that day. However, collecting food contact surface samples when FDA product is being produced would provide the establishment with useful information regarding its overall sanitary practices.", "FSIS Listeria Guideline January 2014 90 observations, providing more information about sources of harborage or cross contamination in the establishment. If positive samples are

found, the establishment should take corrective actions and collect follow-up samples according to their alternative. In addition, the establishment should target the sites during future routine discretionary sampling, to ensure that the contamination has been addressed. For more information on follow-up sampling see Chapter 4. Examples of FCSs may include: \u2022 Conveyor belts, \u2022 Slicers, \u2022 Utensils, \u2022 Tubs, \u2022 Trays, and \u2022 Racks. A table of other possible FCSs and NFCSSs is provided in Attachment 3.1. As indicated in the table, depending on the establishment\u2019s process some surfaces that would normally be NFCSSs may be considered FCSs if they come into direct contact with the product. For example, employees\u2019 gloves should be identified as FCSs if employees directly handle the product with their gloves. Also, some NFCSSs are adjacent to products (e.g., equipment sides) and are more likely to contaminate product (see Section 3.6 for more information on sampling NFCSSs). Size of the Sampling Sites FSIS recommends that establishments sample a 12\u201dx12\u201d area, when possible. If the sampling site (e.g., tool or control button) is smaller than 12\u201dx12\u201d then a smaller size can be sampled. This sampling size is recommended to provide a representative sample of the equipment and is the same as the sample size FSIS uses when collecting samples (see Appendix 3.2). Therefore, it should help provide similar opportunity for detecting contamination as the FSIS sampling method, when used in conjunction with sampling and analysis methods meeting FSIS expectations (see Section 3.5).

3.4 Frequency of Sampling and Explanation of this Frequency According to the Listeria Rule, establishments in Alt. 2b and 3 are required to state the frequency of testing and include an explanation of why the testing frequency is sufficient to maintain control of Lm or an indicator organism (9 CFR 430.4(b)(2)(iii)(C) and (E) and (3)(i)(C) and (E)). Specifying the sampling frequency is also recommended for establishments in Alt.1 and 2a. The sampling frequency should be based on the following criteria: a) Alternative, b) Establishment size or volume (large, small, very small)<sup>4</sup>, c) Whether or not the establishment produces deli meats and hotdogs, and d) Past history and observed patterns of contamination.

4 Large establishment are those with 500 or more employees, small establishment are those with 10 or more employees, but fewer than 500 employees, and very small establishments are those with fewer than 10 employees or annual sales of less than \$2.5 million.", "FSIS Listeria Guideline January 2014 91 Other factors to consider are type of product, how often product is produced, production volume, product flow, traffic patterns, age of the processing facility, and whether raw product is produced in the same room as RTE products (or produced using the same equipment). Establishments can use the minimum sampling frequencies in Table 3.1 below to meet the requirements of the Listeria Rule. Establishments may prefer to increase their testing frequency in response to positives or Listeria trends (see Section 4.5).

Table 3.1 Minimum Routine Sampling Frequencies for Testing of Food Contact Surfaces (FCS) for Alternatives 1, 2, and 3.

Alternative	Daily Production Volume Ranges (lbs)**	Food Contact Surface (FCS) Testing Minimum Frequency*
Alternative 1	2 times/year/line (every 6 months)	2 times/year/line (every 6 months)
Alternative 2a and 2b	4 times/year/line (quarterly)	4 times/year/line (quarterly)
Alternative 3 Non-deli, non- hotdogs	1 time/month/line (monthly)	1 time/month/line (monthly)
Alternative 3 Deli, hotdogs	HACCP Size: Very small 1-6,000 1 times/month/line (monthly)	HACCP Size: Very small 1-6,000 1 times/month/line (monthly)
	Small 6,001 \u2013 50,000 2 times/month/line (every 2 weeks)	Small 6,001 \u2013 50,000 2 times/month/line (every 2 weeks)
	Large 50,001->600,000 4 times/month/line (weekly)	Large 50,001->600,000 4 times/month/line (weekly)

\*At least 3-5 samples per production line should be sampled each time (every 6 months, quarterly, monthly, biweekly or weekly). \*\*Establishments producing deli or hotdogs under Alt. 3 may decide to collect samples based on HACCP size or

production volume. Frequency Determinations: How to use Table 3.1 The table lists FSIS expectations for minimal sampling frequencies to meet the Listeria Rule. Establishments should consider these frequencies when determining their sampling frequency for their routine sampling program. Establishments can keep this table on file as part of the supporting documentation needed to explain why the testing frequency they have selected is sufficient to control Lm or an indicator organism according to 9 CFR 430.4(b)(2)(iii) (E) and (3)(i)(E). The table has been updated to provide Alt. 3 deli and hot dog Question: Can the food contact surface samples be composited (combined) at the laboratory, so that one result is obtained from all 5 samples? Answer: Yes. Establishments may request that laboratories composite food contact surface samples in order to decrease costs. However, establishments should collect the samples individually to avoid cross contamination and take corrective actions for all sites that are part of a composited sample if a positive result occurs, as described on page 95." , "FSIS Listeria Guideline January 2014 92 producers with the option of using daily production volume ranges or establishment HACCP size to determine sampling frequencies. Basing the sampling frequency on the production volume provides more risk-based sampling frequencies and is similar to FSIS sampling programs. If the establishment chooses to follow the testing frequency based on daily production volume, it is important that it modifies the documentation associated with its sampling programs. It would not be sufficient for the establishment to make modifications to its testing frequency without changing its programs and supporting documentation. When the establishment is using the sampling frequencies specified in the table, at least 3-5 FCS samples per production line should be sampled each time (every 6 months, quarterly, monthly, biweekly, or weekly). The samples should be taken at different days throughout the year, quarter, month, or week, and on different shifts (e.g., 1st and 2nd shift) to ensure that the samples are truly representative of processing conditions. The frequencies listed in the table are based on a typical processing schedule (5 days a week). Establishments that produce intermittently may be able to support sampling less frequently depending on the production schedule. Establishments operating under multiple alternatives that use the same FCS during a production day (clean-up to clean-up) should use the testing frequency for the highest risk product. For example, if an establishment produces hotdog products under Alt. 1 and deli products under Alt. 3 using the same equipment on the same processing day, they should sample at the frequency listed for Alt. 3. As stated previously, the sampling frequencies for FCS testing suggested in the Table 3.1 are recommended minimum frequencies. These sampling frequencies should be increased, or additional intensified samples should be added, based on a change in risk including the following: a) Construction activities, b) Change in the HACCP plan or addition of a new HACCP plan, c) Addition of a new product, d) Roof leaks, condensation, equipment breakdowns, or other events that could change or increase the probability of product contamination, e) Increased positives from routine sampling, or Sample Frequency Considerations \u2022 Intermittent Production: Establishments that produce RTE product intermittently may be able to justify sampling at a lower frequency, based on the number of days they produce. For example, assuming that if there are 20 production days in a typical production month (excluding weekends), and an establishment produces RTE product 1-2 days a week, then it may be able to justify sampling quarterly rather than monthly. \u2022 Representative: Samples should be representative of conditions at the establishment and collected over different shifts and seasons. \u2022 Sampling Frequency: Establishments are

expected to increase their sampling frequency in the event of a positive or other event (e.g., construction) in the establishment. NOTE: Once an establishment has identified a sampling frequency, it should follow the frequency it has selected. If sampling is not performed at the stated frequency, the establishment would need to provide support that their surfaces are sanitary and free of Lm." , "FSIS Listeria Guideline January 2014 93 f) Increased aerobic plate count (APC) or bioluminescence counts indicating sanitation issues. NOTE: Establishments operating under multiple alternatives that use the same FCS during a production day (clean-up to clean-up) should use the testing frequency for the highest risk product. For example, if an establishment produces hotdog products under Alt. 1 and deli products under Alt. 3 using the same equipment on the same processing day, they should sample at the frequency listed for Alt. 3. Question: Our establishment produces a tamale product (meat and cheese filling wrapped in a corn husk). Would this product be considered post-lethality exposed? Answer: Yes. The corn husk is not considered a sealed package. Therefore the tamale would be considered a post-lethality exposed product and FCSs that come in direct contact with the product should be sampled. Question: Our establishment produces a product that is cooked in a casing that is clipped on the ends. The product is not removed from the casing until it reaches the consumer. Would this product be considered cook-in bag, and therefore not post-lethality exposed? Answer: It depends. If the establishment can provide documentation from the manufacturer of the casing material demonstrating that it is not permeable to microorganisms and microorganisms cannot penetrate the packaging at the clip, then the product would be considered non post-lethality exposed (or cook-in bag). If the casing is considered semi-permeable (permeable to microorganisms) then the product would be considered post-lethality exposed. Question: Our establishment produces pickled pig's feet. Would this product be considered post-lethality exposed? Answer: No, pickled pig's feet are typically not considered post-lethality exposed because the product is packaged in a jar with a brine and pickle solution that causes reduction of Lm and does not allow growth. As long as the establishment can provide supporting documentation that at least a 5-log decrease of Lm is achieved by the pickle solution, the product would not be considered post-lethality exposed. Question: Our establishment uses brine to cool post-lethality exposed RTE product. Should we sample the brine? Answer: Yes. If the brine comes in direct contact with RTE product, it should be sampled as a FCS. If the product is packaged in an impermeable membrane, the brine should be sampled as a NFCs. , "FSIS Listeria Guideline January 2014 94 3.5 Sample Collection and Laboratory Testing Methods Sampling using proper collection technique is important to ensure that low levels of Lm or Listeria spp. are detected in the post-lethality processing environment. It is also important that results are accurate and reliable, so they can be used to support the decision made in the hazard analysis that Lm is not reasonably likely to occur in the product. The establishment should provide written instructions for collecting food contact, environmental surface or product samples, and the samples should be collected using aseptic techniques (see box below). The instructions can be included as part of the establishment's Listeria Control Program. In Appendix 3.2, the sampling procedures used by FSIS during IVT and RLm sampling to sample FCSs, NFCs, and brine used to chill RTE product are provided. Establishments may use these methods, or adjust the methods based on the needs of the establishment. FSIS expectations for sampling and testing methods are provided below. Further sampling and testing considerations are included in Appendix 3.3. See the box

on the next page for FSIS expectations for sampling methods." , "FSIS Listeria Guideline January 2014 95 Sampling Methods Aseptic Technique: Sampling should be performed by a person trained in aseptic technique and samples should be collected using sterile sponges or other sampling devices. Sample size: A 12\u00d712 area should be sampled, when possible, for FCS and NFCS surfaces. If the surface area is smaller than 12\u00d712, then the entire surface should be sampled. NOTE: Cotton-tip swabs and other smaller sampling devices are not recommended for sampling large areas (12\u00d712) because they may become easily saturated with microorganisms. If these devices are used, FSIS recommends collecting a smaller sampling size according to the manufacturer's instructions to equal a 12\u00d712 area. Sample collection: The sponge or sampling device should be hydrated with sterile neutralizing buffer, Dey Engley (DE) broth, or another sterile broth that contains components that can neutralize the effects of sanitizers that may be present in the sample. When to collect samples: Some samples can be collected at pre op, but most samples should be collected at least 3 hours into operations, if possible, to allow Lm to work its way out of the equipment. If the establishment typically produces RTE product for less than 3 hours then the samples can be collected less than 3 hours into operations. Sample integrity: Samples should be stored under refrigeration before analysis. Samples should be properly labeled to avoid confusion regarding testing results. Brine sampling: Some establishments use brine to cool or inject into RTE product. Depending on whether the finished product surface is directly exposed to brine after the lethality step, the brine solutions could be considered either as food contact or environmental samples. Sample compositing: FCS samples may be composited (combined) in order to conserve establishment's resources. If compositing is performed, FSIS recommends that no more than 5 samples be composited, and separate sponges (or other sampling device) be used to collect each sample, to avoid possible cross contamination. One laboratory test can then be performed on the 5 separate samples, decreasing the cost to the establishment. In addition, individual locations for the composite sample should be noted to assist in determining the site of contamination to facilitate follow-up testing. If a composited sample tests positive, the establishment should consider all the sites represented by the sample as positive and take corrective actions accordingly. During follow-up sampling of FCSs, the sites should be re-sampled individually, along with additional swabs in the area. For more information on compositing, see Appendix 3.3. Handling and shipping of samples: If the samples will be analyzed by an in-house lab, testing should be initiated immediately after collection. If not tested by an in-house lab, the testing should be initiated within 2-3 days of collection. If this is not possible, the establishment should provide evidence that another strategy does not compromise the sensitivity of the method. The samples should be stored under refrigerated conditions (33 \u00b0C to 45 \u00b0F), and in no case be allowed to freeze, which could kill organisms captured on the sampling device. Samples should be placed into insulated shipping containers and sent refrigerated to the laboratory. Lastly, the identity of the sample should be maintained during testing to ensure that sites are correctly identified." , "FSIS Listeria Guideline January 2014 96 Testing Methods Establishments may test for Lm, Listeria spp., or LLO. Testing can be performed either in-house or at a third-party laboratory (see Appendix 3.3). However, if the testing is performed at a third-party laboratory, the establishment should be familiar with the method used by the lab, have the method on file at the establishment, and know whether it meets FSIS expectations for testing methods. If an

establishment uses the testing results to support the decision made in its hazard analysis that Lm is not reasonably likely to occur in its product, then it is important that the results are reliable and accurate. Further information on testing methods can be found in Appendix 3.3. The following are FSIS\u2019s expectations for testing methods: 1) An enrichment step is used to allow for recovery of injured organisms and growth of Listeria to levels that can be detected by most testing methods. Many commonly used testing methods are unable to detect levels below 100 cells\sample. Therefore, it is important that the enrichment step be designed to allow low levels of cells that may be present in the sample to grow to detectable levels. It is also important to allow injured cells time to recover so that they can be detected by the testing method. In most cases, at least an 8-hour enrichment is needed to achieve adequate levels of Lm growth for detection. A one-hour resuscitation step is not an enrichment step, and would likely not be sufficient to detect low levels of Listeria spp. or Lm. 2) The entire sponge or sampling device is analyzed. Some methods involve testing just a small part of the broth or other diluent used to hydrate the sponge or sampling device. Studies have shown that bacteria are likely to be trapped on or in the interior of the sponge or other sampling device. Therefore, FSIS suggests that the whole sponge or sampling device be included in the enrichment step. Analyzing the entire sampling device will help ensure that cells that are present will be detected. 3) The method has been validated. All screening methods should either be used by a regulatory body (e.g., FDA Bacterial Analytical Manual (BAM)), or validated by a recognized independent body (e.g., AOAC, AFNOR, ISO, NordVal, Microval). A validated method from a scientifically robust study using the FSIS Lm qualitative method as a reference method, or other validated cultural methods is also acceptable, but would be subject to FSIS review.<sup>5</sup> In addition to guidance provided by the recognized independent bodies mentioned above, FSIS has provided guidance on the design of validation studies for pathogen testing methods in the FSIS Guidance for Test Kit Manufacturers, Laboratories: Evaluating the Performance of Pathogen Test Kit Methods. <sup>5</sup> Submit request for review of methods to AskFSIS. NOTE: Direct plating methods (e.g., media that is added directly to an agar plate or dehydrated media) that do not include an 8-hour enrichment step would be unlikely to detect low levels of Listeria spp. or Lm. NOTE: It is not sufficient for methods to be AOAC or ISO validated alone. To meet FSIS expectations for testing methods, the method should also include an enrichment step and analyze the entire sponge or sampling device." , "FSIS Listeria Guideline January 2014 97 FSIS Review of Sampling and Testing Methods As part of FSIS Food Safety Assessments (FSA), Enforcement, Investigations, and Analysis Officers (EIAs) will review the sampling and testing methods used by the establishment to determine if they meet FSIS expectations. If an establishment chooses not to use a validated methodology for food-contact and other environmental-surface testing, or if the quality of the testing results provided by the laboratory is in question, the establishment may be assuming a greater risk of allowing adulterated product into commerce. Should FSIS question the sampling or testing methodology, it may choose to review the establishment\u2019s scientific basis for using these methods. In such a circumstance, the establishment could be subject to focused verification checks, including a review of recordkeeping, observation of production, and the collection of product and environmental sampling by FSIS. 3.6 Other Routine Sampling Although not required by the Listeria Rule, establishments may choose to include sampling for indirect and NFCS and product as part of their Listeria Control Program. Sampling indirect and NFCS and product can give the

establishment more information about possible harborage and cross contamination pathways in their environment. For more information on harborage and cross contamination, see Chapter 4. Testing Indirect and Non Food Contact Surfaces (NFCS) As previously stated, establishments may choose to test indirect and NFCS samples as part of their Listeria Control Program, although they are not required by the Listeria Rule. FSIS samples indirect and NFCSs during RLm and IVT sampling, so by sampling these areas, the establishment can find harborage points before they are found by FSIS. Some examples of indirect and NFCS sites are included below. Other examples are included in Appendix 3.1. Indirect FCS sites include the following: The sides of conveyor belts, Equipment frame-work, and Table legs or other areas that are near or adjacent to food processing sites. NFCS sites include the following: Drains, Floors, Walls, and Ceilings. NOTE: If an NFCS tests positive for Lm, the product is not considered adulterated, however a positive finding could indicate insanitary conditions in the environment. Likewise, if a NFCS tests positive for Listeria spp., the product is not considered adulterated, however the establishment should address positive results to ensure that harborage and cross contamination to FCSs and product does not occur.", "FSIS Listeria Guideline January 2014 98 Establishments can set their own frequency for NFCS sampling (e.g., weekly or monthly) based on their processing schedule or past history of positives. While there is no requirement that establishments perform follow-up testing in response to indirect or NFCS samples, it is important that establishments address the source of positives (e.g., by cleaning and sanitation) to ensure that harborage and cross contamination of product does not occur. Product Testing Although product testing is not required by the Listeria Rule (except under hold and test conditions for Alt. 2b or 3), establishments may decide to test product as part of their Listeria Control Program. Product testing can be used as a verification of the effectiveness of establishments' PLTs, AMAPs, and sanitation control measures. Also, as most of FSIS testing is of product (RTEPROD\_RAND and RTEPROD\_RISK project codes), testing by the establishment can help to detect product contamination before it is found through FSIS testing. Many establishments choose to test product quarterly as part of their Listeria Control Programs. However, product testing is not a substitution for the food contact surface testing required by the Listeria Rule. Establishments that test products still need to test food contact surfaces to meet the requirements for Alternatives 2b and 3 (9 CFR 430.4(b)(2)(iii)(A) and (b)(3)(i)(A)). Product testing protocols are typically designed and validated for a 25-gram analytical portion (i.e., the portion of the collected sample that is actually tested). Before testing larger analytical portions from single or multiple composited samples, ensure that the testing method has been validated for use with the larger portion. FSIS has begun compositing 5x25 gram samples collected during RLm sampling into a 125 gram portion. The FSIS Microbiology Laboratory Guidebook (MLG) Chapter 8 methods have been updated to include validated methods for the larger sample size and may be used by establishments to analyze a 125 gram test portion. However, establishments may continue to analyze a 25 gram sample, as 25 grams is the size of the sample FSIS analyzes for the RTEPROD\_RAND and RTEPROD\_RISK project codes. Establishments can set their own frequency for product testing (e.g., quarterly or twice yearly), based on the establishment's processing schedule or past history of positive results (except in hold and test conditions). Product that tests positive for Lm would be considered adulterated and the establishment would be expected to destroy or rework the product with a process that is destructive of Lm. If

a product tests positive for Listeria spp., the establishment should provide the following documentation to demonstrate that the product is not positive for Lm: NOTE: NFCS samples may be collected anywhere in the establishment where RTE products are stored or held (e.g., coolers, freezers, loading docks, and trucks). NFCSS may also be collected in areas associated with post-lethality processing, such as equipment storage and wash rooms, spice rooms, and ingredient rooms. NOTE: The establishment should hold all product lots until its test results are received. This will prevent exposure of the consumer to a potential food hazard. Retaining the product being tested also will eliminate the cost of a recall to the establishment.", "FSIS Listeria Guideline January 2014 99 \u2022 Testing data demonstrating that the original isolate is not positive for Lm, \u2022 A sampling plan that provides a level of statistical confidence that each product is not contaminated with Lm (e.g., testing for Lm using a sampling plan recommended by the ICMSF, see Section 4.3), or \u2022 Documentation showing that the product has been reprocessed using a process validated to achieve at least a 5-log reduction of Lm. A finding of Listeria spp. in the product can indicate insanitary conditions where the product could become contaminated with Lm. Therefore, the establishment should review its Sanitation SOP and HACCP plan to ensure that Lm is controlled in its environment, and that cross contamination of the product is unlikely to occur. FSIS will review the establishment\u2019s sanitation records, observations of sanitation, and sanitation NRs, and if it finds that the establishment\u2019s Sanitation SOP is inadequate or its corrective actions are ineffective, an NR will be issued (according to 9 CFR 416.12 or 416.15), or an IVT may be scheduled at the establishment. If the establishment does not provide compelling documentation that the product is not contaminated with Lm (as described above), FSIS may not be able to determine that the product is not adulterated, and it may take a regulatory control action, under 9 CFR 500.2(a)(3). If the agency determines that product is adulterated by being produced under insanitary conditions, and the product is in commerce, the agency may request a recall.", "FSIS Listeria Guideline January 2014 100 3.7 Glossary Aseptic Technique: A sample-collection procedure performed under sterile conditions. The samples are collected using sterile sampling swabs, buffer, gloves, and other sampling supplies. Aseptic technique should be used to avoid cross contaminating samples, and keep contamination from spreading between sampling sites during sampling. Confirmation Test: A series of tests, often following a positive screening test, used to definitively identify the target organism. Food Contact Surface (FCS): An area in the post-lethality processing environment that comes in direct contact with post-lethality exposed RTE product. Production lot A production lot is the amount of product that may be impacted by a product or FCS positive test result. As previously stated, establishments are required to hold or maintain control of RTE products that FSIS has tested for Lm or RTE products that have passed over food contact surfaces that FSIS has tested for Lm. Establishments may move such products offsite provided that they maintain control of them (e.g., through company seals). A production lot is typically defined as all product produced from clean-up to clean-up unless the establishment can support a smaller lot size. If the establishment performs a complete cleaning and sanitizing (following the procedures in its Sanitation SOP) between lots, the lot size could be reduced. Factors that should be taken into account when determining lot size include RTE source materials used, frequency of cleaning and sanitizing, and processing steps. NOTE: An establishment may reduce its lot size on a day when FSIS collects a sample, in order to facilitate holding the product, as long as the change does not interfere with FSIS\u2019s ability to collect

a representative sample. Products produced in the same room could be considered part of the same or different processing lots, depending on how the lots are separated. If the processing lines can be considered microbiologically and physically independent of one another (i.e. equipment, personnel, utensils, and RTE source materials are not shared among the lines), then they can be considered different lots. An example of a common source material could be chicken in a chicken salad that is taken from the same package over multiple lots. If a FCS tests positive on one line, and the establishment has supporting documentation that there is not cross contamination among the lines, then lots produced on the other lines may not be implicated. Likewise, products produced on the same line could be considered different processing lots, if they are separated by a complete cleaning and sanitization, as well as the other factors described above. NOTE: Products stored in a common cooler would not necessarily be considered part of the same lot. However, the establishments Sanitation SOP should address possible cross contamination, especially if RTE and raw products are held in the same cooler.", "FSIS Listeria Guideline January 2014 101 Indirect Food Contact Surface: An area in the post-lethality processing environment that is adjacent to a FCS, but does not come in direct contact with the product. *Listeria monocytogenes* (Lm): A foodborne bacterial pathogen that can cause the disease listeriosis in humans. *Listeria* spp.: Members of the genus *Listeria*, which includes both pathogenic (Lm) and non pathogenic strains. The presence of *Listeria* spp. indicates conditions where Lm could be present or grow. Further confirmation tests would be needed to determine if *Listeria* spp. positive tests are also positive for Lm. *Listeria*-like organism (LLO): An indicator for Lm. LLO tests usually employ traditional *Listeria* culture enrichment and isolation media to screen for bacteria that have biochemical characteristics typical for but not necessarily exclusive to *Listeria* spp. Many LLO methods are based on the ability of *Listeria* species to hydrolyze esculin or other compounds, resulting in a color change to the broth or solid media (usually to dark brown or black). LLO could include *Enterococcus* spp. and *Lactobacillus* spp., among others. Non Food Contact Surface (NFCS): An area that does not contact product. NFCS samples may be collected from any area where RTE product is held in the establishment (e.g., coolers, freezers, loading docks, and trucks). NFCS samples may also be collected in areas associated with post-lethality processing, such as equipment storage and wash rooms, spice rooms, and ingredient rooms. Production Line: A line refers to the flow of product during production. This includes all of the equipment, personnel, and utensils that contact the RTE product. Multiple individual product lines can meet at a piece of equipment (e.g., packaging machine), but they are still considered to be different lines. Pulsed-field gel electrophoresis (PFGE): a laboratory method used for subtyping bacterial isolates below the level of species using bacterial deoxyribonucleic acid (DNA). PFGE patterns consist of DNA fragments of varying sizes resolved by passage through an agarose gel. PFGE patterns can be compared to determine their degree of relatedness. Screen test: A preliminary test to determine if a sample contains organisms that share certain characteristics (growth parameters, sensitivity to antibiotics, similar genetic make-up) as the target organism. Many tests for *Listeria* spp. are screening tests for Lm. In order to definitively define the organism as Lm, further confirmatory tests would be needed. 3.8 References Tompkin, R.B. 2002. The RTEPROD sampling project uses two project codes: RTEPROD_RAND for product samples selected randomly, and RTEPROD_RISK for post-lethality-exposed product samples selected based on risk. The RTEPROD sampling project is expected to increase response rates and conserve laboratory resources. Under the RTEPROD_RAND project code, both postlethality exposed and non-post-lethality exposed products are tested, and samples are randomly selected by FSIS. FSIS conducts testing on non post-lethality exposed products (e.g., cook-in bag products) to verify that adequate lethality has been achieved in the products, and that they are not contaminated with Lm and Salmonella, in accordance with 9 CFR 417.8(g). Samples are scheduled for the RTEPROD_RAND project code so that all RTE establishments, regardless of plant size, production volume, or process design, have an equal chance of being sampled each fiscal year. The RTEPROD_RISK project code is used primarily to verify that establishments producing post-lethality exposed RTE meat and poultry products are controlling Lm and are in compliance with the requirements of the Listeria Rule. Establishments are identified for sampling based on a risk-ranking algorithm, which takes into account the control alternative,6 the production volume, the type of product produced, and the sampling history. Under both project codes (RTEPROD_RAND and RTEPROD_RISK), a two pound sample of the product in its final finished package is collected, and the sample is tested for Lm and Salmonella spp. Regulations and directives specific to the RTEPROD sampling program include the following: 9 CFR 430.4 \u201cControl of Listeria monocytogenes in post-lethality exposed ready-to-eat products\u201d published on June 6, 2003 (68 FR 34207); FSIS Directive 10,240.4, Revision 3, \u201cVerification Activities for 6 For Alternative 1, the establishment uses a post-lethality treatment for its product and an antimicrobial agent or process that suppresses or limits of growth of Lm. For Alternative 2, the establishment uses a post-lethality treatment for product

or an antimicrobial agent or process that suppresses or limits the growth of Lm. For Alternative 3, the establishment uses a sanitation project that controls Lm contamination in the processing environment and on the product. Question: Why does FSIS require a 2 pound sample of jerky and other RTE products? Answer: The amount of product requested depends on the type and number of tests that are performed. The Agency tests for more than one pathogen in a sample and enumerates the samples. Therefore, at least 2 pounds of product are required for most analyses. One pound of product is required for the RLm project, because only Lm is analyzed. Question: If an establishment delivered product from a sampled lot to a customer but retrieved all of it before the report of the FSIS sample result, will the product be deemed to have been shipped? Answer: Yes, once an establishment completes its pre-shipment record review, the product is considered \u201celigible for shipment\u201d or \u201cshipped.\u201d Upon report of a positive result, establishments are expected to prevent product from entering commerce in accordance with paragraphs 9 CFR 417.3(a)(4) or (b)(3) of the regulations and to process it in a manner that will make it no longer adulterated.", "FSIS Listeria Guideline January 2014 104 the Listeria monocytogenes (Lm) Regulation and Ready-to-Eat (RTE) Sampling Program,\u201d (January 10, 2014). RLm The RLm sampling project, implemented in April 2006, is a routine risk-based sampling project which consists of food contact, environmental and product samples that are taken during the production of RTE meat and poultry products that are exposed to the post-lethality environment. All samples are analyzed for Lm and are to be taken during the same day of production. In conducting the RLm project, it is anticipated that FSIS will be able to assess the compliance of establishments with regulation 9 CFR 430.1 regarding the control of Lm in postlethality exposed RTE production areas and to help ensure that RTE products are safe for consumption at the end of the production process. RLm samples are scheduled using a Food Safety Assessment (FSA) prioritization model which takes into account levels of inspection (LOI),<sup>7</sup> control alternative, and type of product produced. Starting in August 2009, RLms sampling was increased so that establishments producing post-lethality exposed RTE product are sampled at least once every four years under this project. For the RLm project, FSIS collects 3 sample units from large establishments (500 or more employees), 2 sample units from small establishments (10-499 employees) and 1 sample unit from very small establishments (< 10 employees). A sample unit consists of 10 food contact surface swabs, 5 environmental swabs (which are composited), and 5 intact product samples. FSIS laboratories composite the 5 product samples per unit. In establishments that use brine chillers, the EIAO is to collect a sample of brine from each line using a brine chiller. RLm sampling is performed in conjunction with a routine FSA, which provides an in-depth evaluation of the effectiveness of the food-safety practices employed by an establishment. The ability to use the product, contact and environmental sampling information collected from the establishments, can help identify possible risk factors that could be associated with positive results. Regulations and directives specific to the RLm sampling project include the following: 9 CFR 430.4 \u201cControl of Listeria monocytogenes in post-lethality exposed ready-toeat products\u201d published on June 6, 2003 (68 FR 34207) [includes definitions for RTE Alternatives 1, 2, and 3]; and 7 The three LOI are defined as follows: LOI 3\u2014Establishments with strong indications that they are not maintaining effective food safety process controls. LOI 2\u2014Establishments with some indication that they may not be maintaining effective food safety process controls. LOI 1\u2014Establishments that consistently demonstrate they are maintaining effective food

safety process controls. Question: If a product or food contact surface sample tests positive for a pathogen, what is the status of product(s) produced on days subsequent to the day the sample was collected? Answer: In general, FSIS does not consider product that is produced on days subsequent to the day of sampling and that is coded differently from the sampled lot to be represented by the sample. Under most circumstances, the product is not subject to retention, detention, or voluntary recall. A positive sample does call into question the adequacy of an establishment's process for producing safe product, and the establishment should take corrective actions to address the positive result.", "FSIS Listeria Guideline January 2014 105 FSIS Directive 10,240.5, Revision 3, Verification Procedures for Enforcement, Investigations, and Analysis Officers (EIAOs) for the Listeria monocytogenes (Lm) Regulation and Routine Risk-Based Listeria monocytogenes (RLm) Sampling Project published on March 28, 2013. IVT In the IVT sampling project, FSIS tests product, food contact surfaces, and environmental surfaces for Lm. An IVT is initiated after an establishment has a positive Lm result, in either finished product or on a food contact surface. An IVT can also be initiated at the discretion of the District Manager, in response to continuing sanitation non-compliances at the establishments. The IVT is performed after the establishment has taken its corrective and preventive measures in response to FSIS findings. In an IVT, FSIS collects samples in units. A unit consists of 10 food contact surface samples, 5 environmental samples, and 5 product samples per post-lethality exposed RTE processing line in operation on the day of sampling. . If the establishment uses a brine chiller, FSIS will also collect 1 brine sample per line from the brine chiller. IVTs are performed with a cause Food Safety Assessment (FSA) to provide an in-depth evaluation of food safety systems at the establishment. IVTs are scheduled according to the FSA prioritization model, with all establishments with Lm positives receiving an IVT. IVTs may also be performed in response to repetitive occurrences of non compliances because of sanitation issues or to verify corrective actions before closingout an enforcement action. The districts have 30 days in which to schedule the IVT after a product or FCS Lm positive. Regulations and directives specific to IVT include the following: 9 CFR 430.4 \Control of Listeria monocytogenes in post-lethality exposed ready-to-eat products published on June 6, 2003 (68 FR 34207) [includes definitions for RTE Alternatives 1, 2, and 3]; FSIS Directive 10,300.1, Revision 1, \Intensified Verification Testing (IVT) Protocol for Sampling of Product, Food Contact Surfaces and Environmental Surfaces for Listeria monocytogenes, published on March 28, 2013; and FSIS Directive 10,210.1, \Unified Sampling Form published on October 14, 1997." , "FSIS Listeria Guideline January 2014 106 Question: If a RTE product tested by FSIS is found positive for Lm, is the HACCP system automatically considered inadequate? Answer: According to 417.6, the HACCP system may be found inadequate if among other things, the establishment fails to take corrective actions. In determining whether the HACCP plan is inadequate, the Agency will consider whether: 1) some or all products produced under the same or a substantially similar HACCP plan are affected, 2) there have been other incidents of product contamination with the pathogen, 3) if corrective actions have been effective, and 4) if incidents of product contamination have been persistent or recurring. FSIS will review all of this information and consider the entire situation before making a determination of HACCP plan inadequacy. Question: Can an establishment use the results of FSIS verification sampling instead of taking their own product or FCS sample if an FSIS sample is taken at the time the company is

scheduled to take their own sample? Answer: Yes, if FSIS verification sampling occurs within the same time frame as that defined in the establishment's Listeria Control Program, and the same types of samples are collected. For example, if an establishment samples its product once a quarter as part of the verification activities in their HACCP plan and FSIS takes a product sample in that same quarter, then the company can use the FSIS results as part of the verification for their HACCP plan. Likewise, if an establishment samples FCSs once a month, and FSIS samples FCSs during that month, the establishment can use the results from the FCS sampling as part of their own project. However, establishments may not use the results of FSIS product samples in lieu of taking their own FCS samples, because the sample types are different, and the FCSs samples are used to verify the sanitation in the establishment's environment. Question: If a RTE product tested by FSIS is found positive for Lm, is the establishment required to take corrective actions and reassess their HACCP plan? Answer: If Lm control is addressed as a CCP in the HACCP plan (e.g. PLT) the establishment must meet the requirements of 9 CFR 417.3(a), which requires that corrective actions are taken but does not require reassessment of the HACCP plan. If Lm is addressed in the Sanitation SOPs, then the establishment must implement the corrective actions in 9 CFR 417.3(b), which includes reassessment of the HACCP plan. In addition, they must implement the corrective action requirements for the Sanitation SOPs in 9 CFR 416.15, which includes appropriate re-evaluation or modification of the Sanitation SOP. If Lm is addressed in a prerequisite project (e.g., Listeria Control Program) that is used to support the decision that Lm is not a hazard reasonably likely to occur in the product, then the establishment must implement the corrective actions in 9 CFR 417.3(b) and comply with 417.4(a)(3). These regulations state that when there is a change in the process (e.g., a positive result) that could impact the hazard analysis, a reassessment must be performed.", "FSIS Listeria Guideline January 2014 107 Appendix 3.2: FSIS Sampling Procedure I. Sampling Using SpongeSicles" For Food Contact and Non-Food Contact Surface Sampling Equipment needed: Sterile gloves SpongeSicles 10 ml tubes of Dey Engley or other neutralizing broth Marker to label the sample bag 1. Wash and sanitize hands to the mid-forearm. 2. Using ungloved hands open the bag containing the SpongeSicle by pulling off the clear perforated strip at the top of the bag; 3. Pull apart the white tabs to open the mouth of the bag; 4. Aseptically pour 9-10 ml of sterile Dey-Engley (D/E) broth into the bag to hydrate the SpongeSicle, being careful not to contaminate the broth or sponge during the transfer. If the D/E broth is not purple, discard the tube; 5. Press the mouth of the bag back together; 6. Evenly moisten the SpongeSicle by using hand pressure on the outside of the bag to massage the sponge; 7. Position the SpongeSicle so that the handle is sticking out of the bag. Press the top of the bag back together around the handle; 8. Through the bag, squeeze the excess broth gently out of the sponge. Do not let your hand go past the thumb stop on the handle; 9. Aseptically place a sterile glove on the hand used for swabbing by: a. Positioning the glove package so that the L and R (L=left, R=right) are facing the sample collector. When the package is open, the gloves are folded, forming a cuff on the sleeve and lying palm up. Leave them in the package until ready for use; b. Holding the glove for the hand that will be used for swabbing by the inside cuff area. Inserting hand into the glove, palm side up, and lifting the glove from the package. c. Pulling the glove completely on, touching only the fold cuff with your ungloved hand. Do not touch the sterile outside surface of the glove with your ungloved hand. Unroll the fold of the glove. Do not touch any non-sterile surface (clothes, counter tops, or the

outside of the bag containing the SpongeSicle® with the sterile glove. The other hand can be left ungloved for the manipulation of non-sterile surfaces and materials. 10. Using the gloved hand, carefully take the SpongeSicle® out of the bag by grasping the handle and swab the area selected. Be careful to maintain sanitary conditions when;" , "FSIS Listeria Guideline January 2014 108 sampling and collect the samples aseptically. Do not let your hand go past the thumb stop on the handle 11. Swab at least a 1" X 1" square of food contact or environmental surface area, if possible; 12. Swab the chosen area using firm and even pressure: a. Vertically (approximately 10 times); then b. Flip the sponge and use the other side to swab horizontally (approximately 10 times); then c. Swab diagonally, using the same surface side as you used for horizontal (approximately 10 times). 13. Open the bag using the ungloved hand, and insert the sponge portion of the SpongeSicle® back into the bag; 14. Grip the SpongeSicle® through the bag and bend the handle of the SpongeSicle® back and forth with slight force, while gripping the sponge through the bag. The stick should break easily within the sponge (do not break the handle at the thumb stop). Discard the broken handle. If the handle is sticking out above the sponge, discard the sample. Take a new sample following steps 2-13. 15. Squeeze as much air out of the bag as possible and fold the top of the bag down at least 3 times. Fold in the tabs to lock the fold in place; 16. Label the bag with the date and location of the sample. 17. Ship the sample or deliver it to the laboratory as soon as possible for analysis. II. Liquid Sampling for Brine Equipment needed: Sterile gloves 500 ml sterile pitcher or other sample collection device 1000 ml sterile bottle 90 ml D/E broth Marker to label the sample 1. Wash and sanitize hands to the mid forearm. Wear sterile gloves on both hands when collecting a sample; 2. Aseptically pull a 500 ml sterile pitcher (beaker with a handle) from its packaging, being careful not to let the pitcher touch any non-sterile surface, including the exterior of the packaging; 3. Open a collection bottle and with the pitcher aseptically transfer 500 ml of the chill water or brine using the gradations on the side of the collection bottle to ensure the proper volume;" , "FSIS Listeria Guideline January 2014 109 4. Aseptically add 90 ml of D/E to each sample collected to neutralize chlorine and other disinfectants; 5. Tightly cap the collection bottle and gently mix by rotating back and forth; 6. Label the bottle with the date and sample location 7. Send or deliver to the laboratory as soon as possible." , "FSIS Listeria Guideline January 2014 110 Appendix 3.3 Sample Collection and Testing Methods According to the Listeria Rule, establishments in all three alternatives may use verification testing to verify the effectiveness of their sanitation programs (9 CFR 430.4(c)(1)). Using proper sample collection technique is important to ensure that samples provide the best measure of sanitary conditions at the establishment. It is also important that results are accurate and reliable so they can be used to support the decision made in the hazard analysis that Lm is not reasonably likely to occur in the product. Sample Collection Methods As part of its Listeria Control Program, the establishment should provide written instructions for collecting FCS samples, and product and NFCS samples (if performed). The sampling procedure used by FSIS to sample FCSs, NFCSs, and brines during IVT or RLm sampling is provided in Appendix 3.2. Establishments may use this method to sample their FCSs, or adjust the method based on the needs of the establishment. Some establishments use sentinel site programs to collect samples of FCS, NFCS, and product. An example can be requested at the following link: <http://www.tysonfoods.com/Safe-Food/Sentinel-Site-Program.aspx> The box on in Section 3.5 describes FSIS recommendations for establishment sampling methods. As stated in the box,

establishments may choose to composite food contact surface and environmental samples to save laboratory resources. Although compositing food contact surface samples is permissible, establishments should be aware that some loss of information occurs when the samples are composited. For example, if the sample tests positive, the establishment will no longer know what particular site tested positive and would be expected to take corrective actions in all of the sites represented by the composited sample. Therefore, FSIS recommends that establishments collect samples from like areas (e.g., drains in a processing room) in one set of composited samples. Likewise, all of the samples in a composited group could be from the same production line. In that case, a positive result would indicate contamination in a particular area, and establishments could tailor their corrective actions accordingly.

**Laboratory Methods**

Laboratory methods should be fit for the intended purpose, meaning that the test should effectively detect low levels of potentially injured Lm or indicator organisms on food contact or environmental surfaces, including brines, if appropriate. Testing can be performed either inhouse or by a third party laboratory, but the methods used should be reliable and accurate. In either case, it is important that the testing protocol be validated for the purpose, that the procedure is carefully followed (including time and temperature of enrichment and incubation steps), and fresh (non expired) media and testing kits be used. If a third-party laboratory is used, the establishment should be familiar with the method used by the laboratory, have the method on file at the establishment, and know whether it meets FSIS expectations for testing methods. FSIS will ultimately hold the establishment responsible for any 3rd party laboratory results; therefore, if an establishment is unsure whether a testing methodology meets FSIS expectations, it can submit a question through AskFSIS. Guidance for laboratory methods can be found in Section 3.5. Information on selecting a third-party lab can be found in the FSIS Establishment Guidance for the Selection of a Commercial or Private Microbiological Testing Laboratory.", "FSIS Listeria Guideline January 2014 111 Testing for Lm, Listeria spp., or Listeria-like organisms Establishments may choose to test for Lm, Listeria species (Listeria spp.), or Listeria-like organisms (LLO). While Listeria spp. and LLO are appropriate indicators for Lm, most establishments choose to test for Listeria spp., because it is more closely related to Lm. Establishments that test for LLO should take the same actions specified in this guideline for Listeria spp. In many cases, laboratory tests for Listeria spp. are the same initial tests that are used to screen for Lm. \u2022 Tests for Listeria spp. include immunoassays (e.g., lateral flow immunoassays, enzyme linked assay) and nucleic acid based assays (e.g., polymerase chain reaction (PCR), reverse-transcriptase PCR, DNA hybridization). \u2022 LLO tests usually employ traditional Listeria culture enrichment and isolation media to screen for bacteria that have biochemical characteristics typical for but not necessarily exclusive to Listeria spp. Many LLO methods are based on the ability of Listeria species to hydrolyze esculin or other compounds, resulting in a color change to the broth or solid media (usually to dark brown or black). \u2022 If the establishment tests for Aerobic Plate Count (APC), Total Plate Counts (TPC), Total Viable Count (TVC) or bioluminescence-based testing for organic contamination as an indicator for sanitation, they may use the results to indicate where increased Listeria testing may be needed. However, these tests cannot be used to meet sampling requirements for Lm, Listeria spp. or LLO. For more information on use of these tests to verify sanitation see Appendix 2.2.

**Compositing Samples and Pooling Enrichments**

A composited sample is defined as combining sponges from multiple sample sites into a single enrichment media for outgrowth prior to

analysis. This practice saves on the cost of media and analytic testing supplies. FSIS recommendations for compositing samples can be found on page 95. Pooling enrichments is when individual sampling sponges (or other sampling devices) are enriched separately and are combined into a single pool after incubation for analysis. Pooling can save on the cost of analytic testing supplies. However both of these practices can reduce the establishment's ability to quickly identify the source of a Listeria positive result. Pooling enrichments can make it difficult to isolate the source of the positive from the original enrichments. Typically if the result from an analysis of pooled enrichments is positive, the original enrichments are tested to identify the source of the Listeria. FSIS does not recommend going back to the original enrichments after a positive result in a pooled sample unless the follow criteria are met: NOTE: In house labs or third-party labs can be used to analyze the samples, but the sampling methods should be reliable and accurate. NOTE: If an establishment testing FCS for Listeria spp. or LLO receives a positive test result, there is no requirement that the positives are confirmed for Lm. However, establishments are required to take corrective actions according to their Alternative.", "FSIS Listeria Guideline January 2014 112 1) The enrichment times and temperatures are sufficient for the outgrowth of Listeria to levels that would ensure that pooling does not dilute the single sample to levels below the limit of detection of the test. Additional validation of the test method may be required to support this. 2) The time between taking the original enrichment for pooling and taking the individual enrichments for 'isolation' is within validated test kit specifications or can be validated not to significantly affect the detection of the analyte. 3) The enrichments have been handled appropriately during the intervening period (e.g. refrigerated and kept sterile), or a validated re-enrichment procedure is used for subsequent analyses. Re-enrichment is defined as the transfer of an older enrichment to a new enrichment broth with subsequent incubation to ensure sufficient levels of bacteria are present for analysis. Test kit manufacturers may supply guidance on this issue otherwise, a validation study may be needed to demonstrate the effectiveness of the reenrichment procedure. If the screening of the original enrichments returns negative results for all samples, then all the original samples should be considered positive since the original positive result cannot be localized to a single enrichment. Additionally the establishment may want to review the SOP for handling enrichments that may have contributed to a lack of a positive result. Similarly, as described in Section 3.5, if a composited sample tests positive, the establishment should consider all sites represented by the sample as positive. It would not be appropriate to retest individual sites and consider those sites negative, unless the retesting is being performed as a separate, follow-up sampling activity to evaluate the effectiveness of corrective actions. If these criteria are met, then FSIS recommends that no more than 5 enrichments be pooled, and that enrichments from like or similar surfaces are pooled (e.g., cutting board samples with cutting board samples). The individual locations for the pooled sample should be selected and documented to assist in determining the site of contamination to facilitate follow-up testing.

**Confirmation Methods** As stated previously, establishments are not required to confirm samples that are positive for Listeria spp. or LLO. However, if they do choose to confirm the samples, the establishment should follow the recommendations below:

- 1) Culture-based Confirmation Cultural methodology involves enrichment in one or more culture broths, subsequent isolation of a pure culture on solid media, and finally confirmation of culture identity through multiple interdependent and sequential biochemical and genetic tests. The

cultural method should always be performed on the same sample and enrichment broth as the screening test. Common appropriate enrichment-based culture isolation and confirmation methods include the FSIS Microbiology Laboratory Guidebook (MLG) Chapter 8 methods, the FDA BAM culture method and ISO 11290-1. Non-enrichment-based \u201cdirect plating\u201d methods intended for detection of higher levels of Lm, including ISO 11290-2, are not appropriate for detecting low levels of Lm contamination. The cultural method should detect", "FSIS Listeria Guideline January 2014 113 the same group of organisms as the FSIS MLG method. The laboratory procedure should indicate the specific steps taken to confirm the presence of the target microorganism. 2) Non-Culture-based Confirmation Non-cultural methodology does not involve a cultural isolation step, and consists of a single test (e.g., a PCR-based test). This type of confirmatory test is always performed on the same sample and enrichment broth as the screening test. The non-cultural test should identify a different set of characteristics than the screening test (in other words, the same test used for screening, or a similar test, may not be re-used to \"confirm\" the screening result). The non-cultural confirmation test should provide high sensitivity and enhanced specificity (ability to detect true negative results) compared to the screening test and it should be demonstrated and documented to perform acceptably under the conditions of use, which includes the enrichment conditions for the screening test (e.g., enrichment time, temperature, enrichment broth). Acceptable performance is determined by validation, preferably through an independent organization (e.g., the Association of Analytical Chemists (AOAC), Association Fran\u00e7aise de Normalization (AFNOR), ISO, or NordVal). Recording Testing Results Establishments are expected to maintain records of FCS sampling results and other sampling they may perform (product and NFCS) testing. According to the Listeria Rule, establishments must make the verification results that demonstrate the effectiveness of the measures it employs, whether under its HACCP plan, Sanitation SOP, or other prerequisite program, available on request to FSIS (9 CFR 430(c)(7)). The records should include the following: 1) Sample collection and analysis date, 2) Testing result (positive or negative), 3) Analysis that was performed (Lm, Listeria spp., or LLO), 4) Testing method (AOAC number or method name), 5) Technician or laboratory who performed the analysis, 6) Sampling site or product type analyzed. Records can be in electronic or paper format and should be maintained as described in 9 CFR 417.5. NOTE: It would not be appropriate for an establishment to rely on an \u201cinconclusive\u201d or \u201cincorrect\u201d laboratory result. If possible, further analysis should be performed on the original sample or enrichment to determine the testing result. In the absence of further information, the establishment should consider the sample to be positive. Use of Pulsed Field Gel Electrophoresis (PFGE) Data by FSIS When a sample collected by FSIS tests positive for Lm, the isolate is analyzed using Pulsed Field Gel Electrophoresis (PFGE). FSIS plans to start providing PFGE data to establishments on a routine basis, so that they can determine if harborage or cross contamination is occurring in the environment or if there are matches to clinical isolates (see below). PFGE is a laboratory method used for subtyping bacterial isolates below the level of species using bacterial deoxyribonucleic acid (DNA). PFGE patterns consist of DNA fragments of varying sizes resolved by passage through an agarose gel. PFGE patterns are compared to determine their", "FSIS Listeria Guideline January 2014 114 degree of relatedness. Establishments that test for Lm may consider using PFGE to analyze their own testing data to determine whether harborage or cross contamination is occurring in their environment.

Electronic images of PFGE patterns from FSIS and other public health organizations like the Food and Drug Administration (FDA) are uploaded to a central database (PulseNet database) maintained by the Centers for Disease Control and Prevention (CDC), where database managers evaluate and assign IDs to uploaded patterns. FSIS compares the pattern to others from the same establishment (plant comparison), to recently uploaded patterns from listeriosis cases (hotlist comparison), and to all PFGE patterns uploaded to PulseNet (pattern comparison). Because PFGE can't detect small changes in DNA, investigators focus on patterns that are indistinguishable or closely similar (1 or 2 band difference). Isolates with indistinguishable or closely similar PFGE patterns may have shared a recent ancestor and may have originated from a common source, such as a contaminated food product. PFGE data is used to supplement information gathered from other sources (epidemiological investigation, observations at an establishment) and should not be used by itself to demonstrate a definitive link between the product and the illness during outbreak investigations. Lm PFGE pattern data can be interpreted in the following way: 1. Cross contamination is suggested if an identical or highly similar PFGE pattern is found in product and surface samples collected during the same production day. If an identical pattern is found on product and a surface, the surface is more likely to be the source, unless under-processing of RTE product is suspected. 2. Harborage or ongoing contamination of the post-lethality environment is suggested if an identical or highly similar pattern is found in product and surface samples collected over multiple days, weeks, or months. 3. Food-borne exposure is suggested if the identical PFGE pattern is found in FSIS and case-patient samples, especially if the pattern is rare. Information associated with samples with indistinguishable PFGE patterns is reviewed by the FSIS Office of Public Health and Science (OPHS) staff, and may be shared with Agency staff conducting establishment-based investigations (IVT or FSA) and food-borne illnesses investigations. The PFGE data is used to supplement concurrent investigations and does not alter the regulatory implications of microbiological test results.", "FSIS Listeria Guideline January 2014 115 Chapter 4 FSIS Listeria Guideline: Enhanced Sampling Program 4.1 Follow-up Sampling Table 4.1: Timeframe for Follow-up Sampling, Intensified Sampling, and Hold and Test Performed in Response to Positive Food Contact Surface Results 4.2 Intensified Sampling 4.3 Hold and Test 4.4 Reprocessing Lm Contaminated Product 4.5 Determining Listeria Trends 4.6 Glossary 4.7 References Appendices 4.1 Sampling Scenarios by Alternative 4.2 Hold and Test Scenario 4.3 Listeria Trends Examples 4.4 Findings from Food Safety Assessments (FSAs) This chapter provides information on developing an Enhanced Sampling Program as part of the Listeria Control Program. The Enhanced Sampling Program includes follow-up and intensified sampling performed in response to a food-contact surface (FCS) result from the routine-sampling program. Sections on developing Hold and Test Programs and determining Listeria trends are also included in this chapter. 4.1 Follow-up Sampling According to the Listeria Rule, establishments in Alt. 3 (deli and hotdog producers) are required to conduct follow-up testing (sampling) in response to FCS positive sampling results (9 CFR 430.4(b)(3)(ii)(A)). If follow-up testing (sampling) yields a second FCS positive result, then products must be held and tested using a sampling plan that will ensure that products are not adulterated with Lm before they are released into commerce (9 CFR 430.4(b)(3)(ii)(B)). In response to a positive FCS result, establishments in Alt. 1, 2, and 3 (non-deli or hotdog producers) are required to perform corrective actions (9 CFR 416.15(a) and (b) and 417.3(a) and (b)). FSIS recommends that they also perform follow-up sampling in

response to a positive FCS result. By making efforts to find and address the source of contamination in the environment, establishments can take proactive steps to avoid Lm contamination of products. Appendix 4.1 Question: An establishment produces hotdog and deli products using Alt.3 and has 3 production lines in the post-lethality processing area. The establishment receives a positive result for Lm or indicator organism on line 1 FCS. Does the establishment need to sample FCSs only from line 1 or from all the 3 lines for the follow-up testing? Answer: The follow-up sampling is verification that the corrective actions taken by the establishment are effective. If the establishment can support that line 1 is using equipment, personnel and processing area that is separate and independent of the other lines (i.e., not used by other lines) and has supporting documentation that there is no history of cross-contamination among the three lines, then follow-up testing and corrective actions should be conducted on line 1.,"FSIS Listeria Guideline January 2014 116 provides step-by-step guidance for sampling in each Alternative. The establishment\u2019s follow-up testing program can be included as part of its Listeria Control Program in its Enhanced Sampling Program. In the Listeria Control Program, the establishment should specify the number of samples it will collect during follow-up sampling. FSIS recommends that 3-5 samples are collected from the site of the original FCS positive and the surrounding area. According to the Listeria Rule, establishments in Alt.3 deli and hotdog producers must conduct follow-up sampling that includes the specific FCS site that tested positive, as well as such additional tests in the FCS area as are necessary to ensure the effectiveness of the corrective actions. These may include other FCSs that are upstream from the original positive. It would be useful for the establishment to record the rationale for selecting follow-up sampling sites. For example, if a slicer tests positive, the establishment may choose to sample the conveyor or other equipment leading up to the slicer. Follow-up sampling could also include other FCSs on the same piece of equipment that were not previously tested (e.g., slicer blade or plate) or employees\u2019 gloves that come in contact with the product as it is placed on the slicer. The establishment should also include a brief description of corrective and preventive actions that will be taken in response to positive results (details can be included in the Sanitation SOP) and response to positive results (next steps). As stated previously, establishments in Alt. 3 (deli and hotdog producers) are required to hold and test product in response to a second positive test (obtained during follow-up testing) for Lm or an indicator organism. After the 2nd consecutive positive, the establishment should also enter into intensified sampling mode to find the source of positives (see Section 4.2). It is also recommended that establishments in the other alternatives enter into intensified sampling mode after the 2nd positive (although hold and test is not required at this point).

Recommendations for follow-up testing, intensified testing, and hold and test are provided in Table 4.1. Sampling scenarios by alternative can also be found in Appendix 4.1. Table 4.1 Timeframe for Follow-up Sampling, Intensified Sampling, and Hold and Test Performed in Response to Positive Food Contact Surface Results Alternative After the 1st positive After the 2nd positive After the 3rd Positive After Multiple Positives Alternative 1 Follow-up sampling Intensified sampling Hold and test recommended Alternative 2 , Choice 1 (2a) Follow-up sampling Intensified sampling Hold and test recommended Alternative 2, Choice 2 (2b) Follow-up sampling Intensified sampling Hold and test required\* (recommended after 3rd positive) Alternative 3 Follow-up sampling Intensified sampling Hold and test required\* (recommended after 3rd positive) Alternative 3 (deli or hotdog) Follow-up sampling required Intensified

sampling Hold and test required after 2nd positive. \*Establishments in Alt. 2b and 3 (non-deli or hotdog producers) are required to identify when they will hold and test product. FSIS recommends that they do so after the 3rd consecutive", "FSIS Listeria Guideline January 2014 117 positive. Establishments in Alt 3 (deli and hotdog producers) are required to hold and test product after the 2nd consecutive positive. 4.2 Intensified Sampling FSIS recommends that all establishments enter into intensified sampling mode after a 2nd FCS positive. Intensified sampling mode includes: \u2022 Intensified samples collected from FCSs, indirect and NFCSSs, and product, and \u2022 Escalated intensified cleaning and sanitation (details included in the establishment\u2019s Sanitation SOP). Intensified sampling may include the collection of FCS, NFCS, and product samples, and is performed to find sources of harborage and cross contamination in the post-lethality processing environment. Harborage is defined as the persistence of Lm in the establishment over time. Once a harborage point is formed, Lm may transfer through cross contamination onto FCSs or the product. Examples of conditions that may lead to cross contamination include condensation dripping onto product or FCSs, aerosolization from the drains, splashing from the floors, or product brushing against doors, walls, or pallets. For more examples of cross contamination and harborage, see Appendix 2.2.). Procedures for intensified sampling can be included in the establishment\u2019s Listeria Control Program. During intensified sampling, at least 3-5 samples should be collected per site that was found positive during follow-up sampling. Efforts should also be taken to find and address sources of harborage, track cross contamination in the establishment, and to find and address Listeria trends (for more information on Listeria trends, see Section 4.5). As part of its Listeria Control Program, the establishment should also include a response to positive results found during intensified testing. The finding of three consecutive positive samples for Listeria spp. from the same sampling site indicates a serious contamination issue, and increases the risk that product could be contaminated with Lm. The establishment should be taking preventive steps such as: \u2022 Increasing its routine sampling for Listeria, \u2022 Collecting intensified samples to find sources of harborage and cross contamination, \u2022 Holding and testing product (Alt. 2b and 3 non-deli or hotdog producers), \u2022 Reassessing its Sanitation SOPs to determine if sanitation issues could be leading to positive results, \u2022 Assessing the effectiveness of its PLT or AMAPs to address the increased likelihood of positives, Intensified sanitation efforts should be used in conjunction with intensified sampling after the 1st positive result to address sources of contamination. Intensified sanitation includes sanitation measures that are performed in addition to normal sanitation procedures and are escalated in response to continuing findings of positives. Intensified sanitation can include increasing the frequency of cleaning and sanitizing for certain pieces of equipment, breaking down the equipment into its parts for further cleaning, repairing or replacing broken equipment, and construction, if needed. For more descriptions of intensified sanitation, see Appendix 2.2.", "FSIS Listeria Guideline January 2014 118 \u2022 Determining whether Listeria trends exist (see Section 4.5), and \u2022 Reassessing its HACCP plan,8 to determine if the actions it is taking are effective in controlling Listeria. 4.3 Hold and Test According to the Listeria Rule, establishments in Alt. 3 (deli and hotdog producers) are required to hold product after a 2nd consecutive food contact surface positive for Lm or an indicator organism until the establishment corrects the problem indicated by the test result (9 CFR 430.4(b)(3)(ii)(B)). Further, in order to release product into commerce, the establishment must sample and test the lots of product using a method that will

provide a level of statistical confidence that the product is not adulterated (for more information see International Commission on Microbiological Specifications for Foods (ICMSF) Sampling Plans for Lm below). Alternatively, the establishment may rework or condemn the product (9 CFR 430.4(b)(3)(ii)(C)). Establishments in Alt. 3 (non-deli or hotdog producers) and Alt. 2b are required to identify when they will hold and test product ((9 CFR 430.4(b)(2)(iii)(B) and (3)(i)(B)) and FSIS recommends that they do so after the 3rd positive (see Table 4.1). As stated in the note above, the finding of three consecutive positive samples increases the risk that the product could be contaminated with Lm. If the establishment does not hold and test the product after the 3rd positive, it should provide other support demonstrating that the product is not likely to be contaminated. In addition, FSIS recommends that establishments in Alt. 1 and 2a hold and test product after multiple positives for Lm or an indicator organism. Establishments can include their hold and test procedures in their Listeria Control Program. Products can be tested for either Lm or Listeria spp.; however, if a product tests positive for Listeria spp. an establishment may be asked to provide further evidence (such as confirmatory testing results) to demonstrate that the product is not contaminated with Lm (see Section 3.6). Establishments should hold the entire product lot (and subsequent day\u2019s lots) until control is regained. For more information on defining product lots, see Section 3.5. Control is considered regained after 3 consecutive days of negative FCS results are obtained, and all other NFCS and product samples are negative. If product tests positive for Lm during hold and test (see Appendix 4.2), then the product lot represented by the sample is considered adulterated. A hold and test scenario is provided in Appendix 4.2 that provides a day-by-day description of hold and test procedures. Establishments should also describe product disposition in response to positives (procedures for reworked or condemning the product). Hold and test can only be used as a means to release product in situations where an FCS tests positive for Listeria spp. If FCSs or product tests positive for Lm the product is 8 Reassessment of the SSOP or HACCP plan is required in response to an FSIS Lm positive according to 9 CFR 417.3(b) and 416.15 (b) (see the Q&As in Appendix 3.1 for more information). NOTE: The finding of three consecutive positive samples from the same sampling site indicates a serious contamination issue, and increases the risk that product could be contaminated with Lm. NOTE: Control is regained after 3 consecutive days of negative FCS results are obtained, demonstrating that corrective actions are sufficient to address the contamination issue.", "FSIS Listeria Guideline January 2014 119 considered adulterated. In that case, testing product would not be an appropriate means of determining product safety, because even the best-designed testing program cannot detect all Lm that may be present. Therefore, product testing cannot be used as a means for the establishment to release adulterated product into the marketplace. International Commission on Microbiological Specifications for Foods (ICMSF) Sampling Plans for Lm According to the Listeria Rule, establishments in Alt. 3 producing deli or hotdog products must sample and test lots for Lm or an indicator organism using a sampling method and frequency that will provide a statistical level of confidence that ensures that each lot is not adulterated with Lm (9 CFR 430.4(b)(3)(ii)(C)). In order to meet this requirement, FSIS recommends that establishments use the International Commission on Microbiological Specifications for Foods (ICMSF) Tables. Additionally, FSIS recommends that establishments in other alternatives use these tables if they hold and test product. ICMSF categorizes microbial hazards according to risk: 1) Moderate 2) Serious 3) Severe ICMSF describes 15 different cases of sampling plans, with sampling plan

stringency based on degree of risk and the effect on risk of the conditions of use. Cases 10, 11, and 12 would apply to the serious category and cases 13, 14, or 15 would apply to the severe category of microbial hazards. ICMSF considers cases 13, 14, and 15 to apply to foods intended specifically for highly susceptible individuals (e.g., patients in hospitals and nursing homes) because a large proportion of the individuals would be potentially susceptible to foodborne illness; thus, increasing the stringency of the sampling plans is appropriate. FSIS also expects establishments that produce product for the school lunch program to use cases intended specifically for high-risk populations, because of the potential for increased risk in that population. NOTE: If a FCS or product tests positive for Lm, the product is considered adulterated. Product testing can't be used as a means to demonstrate that the product is safe. The product must be reworked or condemned, and FSIS would typically request that establishments recall such products if they have been released into the marketplace. NOTE: ICMSF ranks Lm as either a serious hazard in foods for the general population or a severe hazard in foods for restricted populations (high risk groups e.g., hospital and nursing home patients). Question: Should the ICMSF sampling plan be used for regular sampling or only for hold and test sampling? Answer: For routine sampling, the establishment can use whatever sampling plan it justifies as appropriate to demonstrate that the product is safe. For hold and test sampling for Lm, a statistically-based sampling plan should be used. The ICMSF table provides examples of statisticallybased sampling plans that are commonly used for demonstrating lot acceptance." , "FSIS Listeria Guideline January 2014 120 For cases 10 or 13, conditions of use reduce risk (e.g., the numbers of Lm will decrease). For cases 11 and 14, conditions cause no change in the hazard (e.g., the organism cannot grow), and for cases 12 and 15, conditions may increase the risk (e.g., foods in which Lm can grow are subjected to conditions that allow growth). Sampling plans for the cases are given in the table below, where n is the number of samples and c=0 means that none of the n samples can be positive for Lm. The table also provides the sampling plan performance, assuming a log-normal distribution with a standard deviation of 0.8; lots having the calculated mean concentrations or greater will be rejected with at least 95% confidence. Each of these plans achieves assurance that Lm is present at <1 CFU in the sample size. FSIS recommends analyzing a 25 g sample. If the risk of the population is unknown, FSIS recommends that establishments use cases 13-15. Conditions reduce concern Conditions cause no change in concern Conditions increase concern Case 10 n=5, c=0 Mean Concentration 1 cfu/32g Case 11 n=10, c=0 Mean Concentration 1 cfu/83g Case 12 n=20, c=0 Mean Concentration 1 cfu/185g Case 13 n=15, c=0 Mean Concentration 1 cfu/135g Case 14 n=30, c=0 Mean Concentration 1 cfu/278g Case 15 n=60, c=0 Mean Concentration 1 cfu/526g When RTE products must be sampled (hold and test) under the Listeria Rule, the number of samples (randomly selected) would be as specified for these cases based on the risk of the product and the intended consumers. Since deli and hotdog products are ranked as the top causes of foodborne illness, the establishment producing these products should select these products to be sampled first. Sampling starts after the establishment has conducted corrective actions that are specifically designed to find the most likely cause of the contamination and controls are put in place to prevent recurrence. Case 10 n=5, c=0 Case 11 n=10, c=0 Case 12 n=20, c=0 Products with continued decline in population due to antimicrobial or other formulation considerations such as pH and Aw. Products in Alternative 1 Products that limit growth (< 1 log) due to antimicrobial or other formulation

considerations such as pH and Aw. Products in Alternative 2 Products that support growth and that will be stored refrigerated for an extended period of time. Products in Alternative 3 Case 13 n=15, c=0 Case 14 n=30, c=0 Case 15 n=60, c=0 NOTE: Product samples should be analyzed separately and not composited. However, if compositing is to be done, composites of 25-g portions should not exceed a total of 125 g in order to maintain the sensitivity of the method of analysis, and a validated method should be used.", "FSIS Listeria Guideline January 2014 121 As for case 10, but where products are produced for a hospital or nursing home or for another higher risk population Products in Alternative 1 intended for a hospital, nursing home or for another higher risk population As for case 11, but where products are produced for a hospital or nursing home or for another higher risk population Products in Alternative 2 intended for a hospital, nursing home or for another higher risk population As for case 12, but where products are produced for a hospital or nursing home or for another higher risk population Products in Alternative 3 intended for a hospital, nursing home or for another higher risk population. The number of samples recommended should be collected in one day and all affected products should be held during the testing period. Testing can be for Listeria spp. or Lm. Any positive results from this follow-up testing (using the ICMSF approach) should lead to more significant investigations of the cause of the contamination. 3. Products that test positive for Listeria spp. may be considered adulterated if the establishment cannot support that the product is not adulterated, or if insanitary conditions exist, see Section 3.6. The establishment should conduct rigorous corrective and preventive actions and other sanitation activities. Establishments may send a letter or certification when they ship tested products to nursing homes, hospital, and other institutions with susceptible populations. Such a letter should indicate that product has been sampled and tested according to ICMSF recommendations. Establishments supplying nursing homes, hospitals and other institutions with susceptible populations are expected to implement whatever additional controls and verification procedures are necessary to ensure that product is not adulterated. 4.4 Reprocessing Lm Contaminated Product Product that tests positive for Lm or an indicator organism, or passes over an FCS that tests positive for Lm, or is suspected to be positive because of sanitation or processing issues at the establishment, may be reprocessed. A process that has been validated to achieve at least a 5log Lm reduction would be accepted by FSIS to reprocess the product. In order to reprocess the product, the establishment may use a processing treatment such as re-cooking and re-cooling the product (see below), applying a PLT (as described in Section 2.1), or other supportable process. An example of a PLT which has been found to achieve a 5-log Lm reduction is HPP. If an establishment chooses to use HPP to reprocess Lm-positive product, then the establishment should have scientific support that demonstrates that the process achieves at least a 5-log reduction of Lm in their particular product (see Appendix 2.1 for more information on validation). In addition, establishments may use both Appendix A and Appendix B of the final rule, \u201cPerformance Standards for the Production of Certain Meat and Poultry Products\u201d FSIS Guidance on Safe Cooking of Non-Intact Meat Chops, Roasts, and Steaks and the TimeTemperature Tables for Cooking Ready-to-Eat Poultry Products, or other supportable processes to reprocess Lm-positive product. When using these guidance documents, establishments should ensure that adequate humidity is maintained during heating according to Appendix A and that C. perfringens and C. botulinum growth is controlled according to Appendix B, or other NOTE: FSIS will consider PLTs achieving at least a 5-log

reduction of Lm sufficient for reprocessing contaminated product.", "FSIS Listeria Guideline January 2014 122 scientific support. Although Appendix A and B, the FSIS Guidance on Safe Cooking of Nonintact Meat Chops, Roasts, and Steaks, and the Time-Temperature Tables for Cooking Ready-to-Eat Poultry Products, are designed to achieve reductions in Salmonella, establishments are not expected to validate that these processes also achieve reductions in Lm because Salmonella is considered an indicator of lethality for Lm (see Appendix 2.1). 4.5 Determining Listeria Trends As described previously, establishments are expected to take corrective and preventive actions in response to positives based on their alternative. One way that establishments can ensure that their corrective actions are effective is to track sampling results. Repeated Listeria spp. positives on FCSs, NFCSSs, or product indicate positive Listeria trends in the establishment. The finding of Listeria trends could indicate that the establishment's Listeria Control Program is not effective in controlling the presence of Lm in the establishment's post-lethality processing environment. In response to a finding of Listeria trends, the establishment should perform intensified testing and sanitation, and conduct a comprehensive investigation to determine the source and the cause of the contamination (the steps in a comprehensive investigation can be found below the section on identifying and addressing Listeria trends). One way to track and address Listeria trends is through a sentinel site program. Identifying and Addressing Listeria Trends Establishments should track their sampling results over time, to identify Listeria trends. Listeria trends can consist of increases in positive samples over a particular time period (e.g., weekly, biweekly, monthly, quarterly, or 6 months) or increases in positives in particular sites or areas (see Appendix 4.3 for specific examples). By tracking their percent positive sampling results, establishments can determine if the percentage of positives in the establishments is increasing, indicating that changes in their cleaning protocols or sanitation procedures should be made. Listeria trends may also exist if positives are seen in a particular area over time. In the example provided in the tracking sheet in Appendix 4.3, positives were found on a freezer fan, wall, floor, and conveyor belt over a six month period. Although the establishment addressed each individual positive by routine cleaning and sanitizing (and the sampling site subsequently tested negative), positives still continued to occur in other areas of the freezer. The Listeria trend was not addressed until cleaning and sanitizing were escalated and repairs made to the freezer. Although every finding of Listeria trends may not require extreme steps such as equipment repairs or replacement, it is important for establishments to track their results in order to address harborage points. For more information on cleaning and sanitizing steps that can be taken to address positive results, see Appendix 2.2. Positive product results for either Listeria spp. or Lm over time could also indicate a Listeria trend. FSIS uses results from its product and RLm and IVT sampling to track trends over time, by comparing pulsed-field gel electrophoresis (PFGE) patterns. These results can be used to demonstrate possible harborage and cross contamination in the establishment (see Appendix 3.3). FSIS may use this data to take regulatory action against the establishment. By NOTE: Repeated Listeria spp. positives on FCS, NFCSS, or product (Listeria trends) could indicate that the establishment's Listeria Control Program is not effective in controlling the presence of Lm in the establishment's processing environment.", "FSIS Listeria Guideline January 2014 123 monitoring and addressing Listeria trends, establishments can take a proactive role in demonstrating that they have controlled contamination in their processing environment. When Listeria trends are identified,

establishments should take corrective actions to address the trend. Corrective actions should include intensified sampling (as described in Section 4.2) and intensified sanitation. Along with intensified sampling and sanitation, establishments should perform a comprehensive investigation to find the source of the problem (see explanation below). Preventive actions, such as increasing sanitation frequency, intensified sanitation in particular areas or equipment, repairing or replacing equipment, increasing testing frequency, and reassessing the Sanitation SOP and HACCP program, should be taken. NOTE: Continued findings of Lm in an establishment's products or contact surfaces could lead to foodborne illness and regulatory action (including suspension of inspection by FSIS). Therefore, it is important to ensure that trends are addressed before the product becomes contaminated.

**Parts of a Comprehensive Investigation** In response to findings of Listeria trends, establishments should conduct a comprehensive investigation into the source of positives, which includes:

- a. Review the cleaning and sanitizing procedures, including the types of cleaning agents.
- b. Review traffic control patterns, equipment layout and adherence to employee hygiene procedures.
- c. Locate possible niches that may represent harborage sites.

- i. Repeated, non-consecutive positives usually indicate the presence of a niche or harborage site for Lm.
- ii. Increase testing of the positive site including individual pieces of equipment to locate the source of the contamination.
- iii. Test upstream in the production area from the initial positives to find the source of contamination.
- iv. Collect at least 3-5 samples per sampling event until negatives are found.

In conjunction with the comprehensive investigation, the establishment should take preventive actions, including examining and reviewing the HACCP plan, Sanitation SOP, or prerequisite project where the sanitation and testing projects are included. As part of this review, the establishment should evaluate these projects to determine if there are any design or execution flaws, and modify them as necessary.", "FSIS Listeria Guideline January 2014 124 4.6 Glossary

**Comprehensive Investigation:** An investigation performed by the establishment to address Listeria trends. As part of this investigation, the establishment should review cleaning and sanitizing procedures, traffic control patterns, and identify sources of harborage.

**Corrective Actions:** Procedures to be followed when a deviation occurs. These include actions the establishment will take to ensure that the cause of the deviation is identified and eliminated, the critical control point (CCP) will be under control after the corrective action is taken, measures to prevent recurrence are established; and no product that is injurious to health or otherwise adulterated enters commerce (9 CFR 417.3(a)).

**Cross Contamination:** Movement of a microorganism (e.g., Lm) from one site to another. Cross contamination may occur in the post-lethality processing area when Lm moves from a harborage area, such as a drain, onto equipment and product.

**Enhanced Sampling Program:** Includes follow-up and intensified sampling, performed in response to a positive FCS result from routine sampling program. Samples should be collected in addition to those collected as part of the routine sampling program.

**Follow-up Sampling:** Collection of a 2nd FCS sample performed in response to a 1st FCS positive result. Follow-up samples should be collected from the specific site of the original positive sample, as well as additional samples of the surrounding FCS areas as necessary to ensure the effectiveness of corrective actions (required for Alt. 3 deli and hotdog processors).

**Harborage:** Persistence of Lm in a processing establishment over time. Harborage areas are areas where bacteria may survive and multiply, and are often NFCSSs that may be cleaned less frequently than FCSs.

**Hold and test:** Product samples that are held and tested by the establishment in response to a 2nd FCS

positive result (required for Alt. 3 deli and hotdog producers), according to the Listeria Rule. In addition, establishments are required to hold or maintain control of RTE products that FSIS has tested for Lm, and RTE products that have passed over food contact surfaces that FSIS has tested for Lm. Establishments may move such products off-site provided they maintain control of them (e.g., through company seals). Intensified Sampling: Sampling performed in response to a 2nd FCS positive testing result. Intensified sampling may include the collection of FCS, NFCS, and product samples, and is performed in order to find sources of harborage and cross contamination in the post-lethality processing environment. Intensified Sanitation: Intensified sanitation includes sanitation measures that are performed in addition to normal sanitation procedures and are escalated in response to continuing findings of positives. Listeria Trends: Repetitive positive FCS, NFCS, or product samples that are not addressed by routine cleaning and sanitation. Listeria trends should be addressed by intensified sanitation and investigative sampling to find sources of harborage and cross contamination. Preventive Actions: Actions taken in response to positive results to prevent further positives from occurring. These may include increased sanitation in particular areas or equipment,","FSIS Listeria Guideline January 2014 125 increased testing frequency, and review and revision of the HACCP program and Sanitation SOPs. 4.7 References International Commission on Microbiological Specifications for Foods (ICMSF). Microorganisms in Foods 7: Microbiological Testing in Food Safety Management. Kluwer Academic\Plenum Publishers, NY. 2002).","FSIS Listeria Guideline January 2014 126 Appendix 4.1: Sampling Scenarios by Alternative The following sections provide steps that establishments can take, depending on their alternative, once a positive is found. For a description of requirements by alternative, see Attachment 1.1. a) Alternative 1 i) Recommended: Conduct tests of food contact surfaces (FCS) for Lm or Listeria spp.) at least twice a year. ii) Sample at least a 12\u201dx12\u201d area for each surface, if possible. iii) Record the test results. iv) If the test results are positive for Lm or Listeria spp.: (1) Take corrective action (as specified in the HACCP plan, Sanitation SOP, or prerequisite program), which should include intensified cleaning and sanitizing. (2) If the FCS test is positive for Lm, the product is considered adulterated. If the FCS is positive for Listeria spp., the product is not summarily considered adulterated, but corrective actions should be taken. (3) Record the corrective actions taken. (4) Collect follow-up samples from the FCS and surrounding areas (recommended). (5) Repeat corrective action and testing until samples are negative for Lm or Listeria spp. (6) Initiate intensified sampling after the 2nd consecutive positive. (7) If FCSs continue to test positive, hold and test product (recommended). v) If the product tests positive for Lm, (1) Recall the product, if already shipped, and (2) Destroy the product, or (3) Re-work the product with a process that is destructive of Lm. b) Alternative 2, choice 1 (Alt. 2a) i) Recommended: Conduct tests of FCSs for Lm or. Listeria spp. at least quarterly. ii) Sample at least a 12\u201dx12\u201d area for each surface, if possible. iii) Record the test results. iv) If the test results are positive for Lm or Listeria spp.: (1) Take corrective action (as specified in the HACCP plan, Sanitation SOP, or prerequisite program) (2) If the FCS test is positive for Lm, the product would be considered adulterated. If the FCS is positive for Listeria spp., the product is not summarily considered adulterated, but corrective actions should be taken. (3) Record the corrective actions taken. (4) Collect follow-up samples from the FCS and surrounding areas (recommended). (5) Repeat corrective action and testing until samples are negative for Lm or Listeria spp. (6) Initiate intensified sampling after the 2nd consecutive positive. (7) If FCSs

continue to test positive, hold and test product (recommended). v) If the product tests positive for Lm, (1) Recall the product, if already shipped, and (2) Destroy the product, or (3) Re-work the product with a process that is destructive of Lm.", "FSIS Listeria Guideline January 2014 127 c) Alternative 2, choice 2 (Alt. 2b) i) Required: Conduct tests of FCSs for Lm or Listeria spp. recommended frequency: at least quarterly. ii) Sample at least a 12\u201dx12\u201d area, if possible. iii) Record the test results. iv) If the test results are positive for Lm or Listeria spp: (1) Take corrective action (as specified in the HACCP plan, Sanitation SOP, or prerequisite program). (2) If the FCS test is positive for Lm, the product is considered adulterated. If the FCS is positive for Listeria spp., the product is not summarily considered adulterated, but corrective actions should be taken. (3) Record the corrective actions taken. (a) Collect follow-up samples from the FCS and surrounding areas (recommended). (4) Repeat corrective action and testing until samples are negative for Lm or Listeria spp. (5) Initiate intensified sampling after the 2nd consecutive positive. v) Holding and testing of product is required\* (recommended after the 3rd positive). vi) If the product tests positive for Lm, (1) Recall the product, if already shipped, and (2) Destroy the product, or (3) Re-work the product with a process that is destructive of Lm.

\*The establishment is required to identify when they will hold and test product. FSIS recommends that it hold and test product after the third consecutive positive result. d) Alternative 3 (non-deli or hotdog products) i) Required: Conduct tests of FCS for Lm or Listeria spp. Recommended frequency: once a month ii) Sample at least a 12\u201dx12\u201d area for each surface, if possible. iii) Record the test results. iv) If the test results are positive for Lm or Listeria spp.: (1) Take corrective action (as specified in the HACCP plan, Sanitation SOP or prerequisite program). (2) If the FCS test is positive for Lm, the product is considered adulterated. If the FCS is positive for Listeria spp., the product is not summarily considered adulterated, but corrective actions should be taken. (3) Record the corrective actions taken. (4) Collect follow-up samples from the FCS and surrounding areas (recommended). (5) Repeat corrective action and testing until samples are negative for Lm or Listeria spp. v) Initiate intensified sampling after the 2nd consecutive positive. vi) Hold and test of product is required\* (recommended after the 3rd positive). vii) If the product tests positive for Lm, (1) Recall the product, if already shipped, and (2) Destroy the product, or (3) Re-work the product with a process that is destructive of Lm.

\*The establishment is required to identify when they will hold and test product. FSIS recommends that it hold and test product after the 3rd consecutive positive result.", "FSIS Listeria Guideline January 2014 128 e) Alternative 3 (deli and hotdog products) i) Required: Conduct tests of FCSs for Lm or Listeria spp. Recommended frequency: (1) Large Establishments: four times per month per line (2) Small Establishments: two times per month per line (3) Very Small Establishments: once per month per line ii) Sample at least a 12\u201dx12\u201d area, if possible. iii) Record the test results. iv) If the test results are positive for Lm or Listeria spp.: (1) Take corrective action (as specified in the HACCP plan, Sanitation SOP, or prerequisite program), which should include intensified cleaning and sanitizing. If the FCS test is positive for Lm, the product is considered adulterated. If the FCS is positive for Listeria spp., the product is not summarily considered adulterated, but corrective actions should be taken. (2) Record the corrective actions taken. (3) Collect follow-up samples from the FCS and the surrounding area (required). (4) Repeat corrective action and testing until samples are negative for Lm or Listeria spp. v) Initiate intensified sampling after the 2nd consecutive positive. (1) Take corrective action (as specified in the HACCP plan, Sanitation SOP

or prerequisite program), which should include intensified cleaning and sanitizing. (2) If the FCS test is positive for Lm, the product in the sampled lot would be considered adulterated. If the FCS is positive for Listeria spp., the product is not summarily considered adulterated, but corrective actions should be taken. (3) Record the corrective actions taken. (4) Hold the product (see hold-and-test scenario below in Appendix 4.2). (5) Test product for Lm at a rate that provides a level of statistical confidence that the product is not adulterated (required after the 2nd consecutive positive result). (6) Conduct follow-up testing of the FCS each day until there are 3 consecutive negative test results for Lm or Listeria spp. (7) At the same time, continue to hold each day's production lot until the test results for the FCS are negative. (8) If the test results for the product are positive for Lm, (a) Destroy the product, or (b) Re-work the product with a process that is destructive to Lm.","FSIS Listeria Guideline January 2014 129 Appendix 4.2: Hold and Test Scenario Hold-and-Test Scenario for Deli and Hotdog Products in Alternative 3 Assuming it takes to 3 days to obtain a test result for Listeria spp.: Day 1 \u2013 Take food contact surface (FCS) samples Day 4 \u2013 If FCS samples (from Day 1) are negative for Listeria spp. \uf0fc Continue production, as the corrective action appears to have resolved the problem and test FCSs as scheduled. If the FCS samples are positive (from Day 1) for Listeria spp.: \uf0fc Take corrective action (as specified in the HACCP plan, Sanitation SOP, or prerequisite program), which should include an intensified cleaning and sanitizing. \uf0fc Collect follow-up samples of FCS\u2014target the most likely source of contamination, and also perform additional tests in the surrounding FCS area. \uf0fc Continue production. Day 7 \u2013 If the follow-up FCS sample (from Day 4) is negative for Listeria spp.: \uf0fc Continue production, as the corrective action appears to have resolved the problem and test the FCSs as scheduled. If the follow-up FCS sample (from Day 4) is positive for Listeria spp.: \uf0fc Take Corrective Action (as specified in the HACCP plan, Sanitation SOP or prerequisite program), which should include an intensified cleaning and sanitizing. \uf0fc Test the FCS-- target most likely source of contamination, and also take additional tests in the surrounding FCS area. \uf0fc Collect intensified samples of FCS, NFCS, and product. \uf0fc Hold and test Day 7 product lot (for Lm). \uf0fc Continue production, hold product from the day\u2019s production. Day 8 \u2013 \uf0fc Test the FCS\u2014target the most likely source of contamination, and also perform additional tests in the surrounding FCS area. \uf0fc Continue intensified sampling of FCS, NFCS, and product. \uf0fc Hold product from this day\u2019s production. Day 9 \u2013 \uf0fc Test the FCSs-- target the most likely source of contamination, and also perform additional tests in the surrounding FCS area. \uf0fc Continue intensified sampling of FCS, NFCS, and product. \uf0fc Hold product from this day\u2019s production. Day 10 \u2013 If the FCS sample (day 7 sample) is negative for Listeria spp.:","FSIS Listeria Guideline January 2014 130 \uf0fc Continue production and hold product from days 7, 8, 9 and 10 until the results from Day 7 product testing and Days 8, 9, and 10 FCS testing are available and found to be negative, unless there is compelling justification that affected products are not adulterated. \uf0fc Resume the FCS testing according to the frequency stated in the HACCP plan, Sanitation SOP, or prerequisite program. If the FCS sample (day 7 sample) is positive for Listeria spp.: \uf0fc Hold and test product from day 10 production. \uf0fc Test product from days 7, 8, 9, and 10 for Lm. \uf0fc Take corrective action. \uf0fc Intensive cleaning and sanitizing. \uf0fc Take FCS sample--target the most likely source of contamination, and also perform additional tests in the surrounding FCS area. Day 14 \u2013 If the Day 7 product is positive for Lm, destroy product, or

rework product with a process that is destructive of Lm. Recall product if already in commerce. If product is positive for Listeria spp., verify by testing that products (Days 7, 8, 9, 10), which may have been exposed to insanitary conditions are not adulterated. Product that is positive for Listeria spp. may be considered adulterated if it was produced under insanitary conditions, see Section 3.6. Question: An establishment that produces Alt. 3 deli and hotdog products tests FCSs on a Monday. The test comes back positive on Thursday. How would this affect the product produced on Monday, Tuesday, Wednesday, and Thursday? Answer: If the test is positive for Listeria spp., the result would not affect product produced on Monday through Thursday. However, on Thursday, the establishment must initiate corrective actions, intensified cleaning and sanitizing, and verify the effectiveness of the corrective actions by follow-up testing of the FCSs. If the test is positive for Lm, product that comes into direct contact with a FCS that tests positive for Lm is considered adulterated and FSIS would typically request that establishments recall such products if they have been released into the marketplace. That product must be destroyed or reworked with a process that is destructive of Lm. The establishment must have supporting documentation explaining why products produced on Tuesday, Wednesday and Thursday would not be contaminated with Lm. On Thursday, when it receives the positive result, the establishment must take corrective actions, conduct intensified cleaning and sanitizing, and test FCSs for Lm or indicator organisms to verify the effectiveness of the corrective actions.", "FSIS Listeria Guideline January 2014 131 Hold-And-Test Scenario Flowchart for Alt.3 (deli or hotdog producers) Test Food Contact Surface (FCS) (Day1) 1st FCS Listeria spp. (+) (Day4) Corrective Action Intensified Cleaning and Sanitizing Continue Production Collect Follow-up Test for FCS 2nd FCS Listeria spp. (+) FCS Listeria spp. (\u2013) (Day 7) Continue Production Test according to frequency in the Sanitation SOP. FCS: food contact surface Listeria spp.: Listeria species (test results available after 2 or 3 days). Lm: Listeria monocytogenes (test results available after 6 or 7 days)", "FSIS Listeria Guideline January 2014 132 Enforcement Strategy for Alternative 3 Deli and Hotdog Products Under the Listeria Rule, an establishment with deli and hotdog products in Alternative 3 must provide for testing of FCSs. If a FCS tests positive for Lm or Listeria spp., the establishment must conduct follow-up testing to verify that its corrective actions are effective. If during the follow-up testing another positive FCS occurs for Listeria spp., the establishment must hold the applicable product lot. If the product is positive for Lm, destroy or rework with a process destructive of Lm, and test the FCS until the establishment corrects the problem as indicated by the test result. In addition, the establishment must test held product lots for Lm using a sampling plan that will provide a statistical level of confidence. The flowchart above shows a hold and test scenario that establishments under hold and test can use. The days described are approximate, depending on the typical amount of time needed to obtain a positive test result (see key at bottom of the

flowchart). Establishments can adjust the flowchart based on their own process and time frame for sample results. The following section describes the likely action and reaction of inspection personnel during a hold and test situation. Day 1 and 4 The testing program and the test results for FCSs and NFCSSs should be made available to inspection program personnel (IPP). In case of a FCS testing positive for Listeria spp., IPP will verify that the establishment is performing the corrective actions as specified in the HACCP plan, Sanitation SOP or prerequisite programs, including any intensified cleaning and sanitizing. For deli and hotdog products in Alternative 3, IPP will verify that the establishment is conducting follow-up testing for FCSs to determine the effectiveness of the corrective actions, targeting the most likely source of contamination, performing additional tests in surrounding FCS area, and recording the results of all these. Day 7 Results of the follow-up FCS tests are available on this day. If the FCS tests are negative, then the establishment continues with its normal production and Sanitation SOP. If the follow-up FCS tests are positive for Listeria spp., , IPP will verify that the establishment is following its corrective action for a second FCS positive, including intensified cleaning and sanitizing. For deli and hotdog products in Alt. 3, inspection personnel will verify whether the establishment is holding the product produced that day and testing the product lot for Lm, and whether the establishment is conducting follow-up testing of FCS during each production day, and holding all products until a negative follow-up FCS test is obtained. Products produced on days 8, 9, and 10 are held until the follow-up FCS test available after about 3 days is found negative. The Listeria Rule states that products must be held until the problem is corrected, as indicated by testing. For establishments in Alt. 3 producing deli and hotdog products, inspection personnel can cite the establishment if these procedures are not followed. Days 8, 9, and 10 The presence of Listeria spp. on a FCS or on RTE product is associated with the potential for an insanitary condition to exist. FSIS expects an establishment to develop a compelling justification for concluding that product produced on days in which insanitary conditions may have existed is not adulterated. Thus, FSIS would further expect that the establishment, on days 8-10, would conduct verification testing on the FCSs to demonstrate that the potential insanitary condition was adequately redressed via the corrective and preventive actions. In addition, to further develop a compelling justification to support the establishment\u2019s decision, FSIS would expect a prudent establishment to also compile data on product testing to confirm and verify that the corrective and preventive actions were effective in preventing product from becoming adulterated.", "FSIS Listeria Guideline January 2014 133 Day 10 If the Day 7 FCS Test is Positive, IPP will verify that if the follow-up FCS test taken on Day 7 is positive, then the day\u2019s production lots of deli and hotdog products in Alt. 3 are held and tested for Lm or Listeria spp, and the same procedures are followed as in the second FCS (+) test as in Day 7. If the FCS samples taken on day 7 are found positive for Listeria spp. on day 10, the establishment should hold and test product produced on days 8, 9, and 10 unless the establishment has supporting documentation to justify that product produced on days 8, 9, and 10 would not be contaminated with Lm. The sampling plan must provide a level of confidence that each product is not contaminated with Lm. Because of 3 consecutive positive FCS samples, the establishment should conduct intensive cleaning and sanitizing and reevaluate its Sanitation SOP. If the FCS sample is positive for Lm, affected product lots are considered adulterated. The establishment should also hold and test products produced on days 8, 9, and 10 because an FCS positive for Lm shows that the corrective action may not have been effective in removing the

contamination and products produced on succeeding days may also be contaminated. If the Day 7 FCS Test is Negative If the FCS samples taken on day 7 are found negative for Listeria spp. on day 10, the establishment should wait for the results of the FCS tests conducted on days 8, 9, and 10 as detailed above, and results of the Day 7 product test before releasing these products. Control is considered regained after 3 days of negative results. Day 14 If day 7 product was found positive for Lm on day 14, affected product lots produced on day 7 are considered adulterated. The establishment must destroy the product lots or rework them with a process destructive of Lm. The establishment should continue holding product lots produced on days 8, 9, and 10 until results of products tests are available, unless the establishment has supporting documentation for why product produced on days 8, 9, and 10 would not be contaminated with Lm. Establishment should also hold and test product produced before day 7 and recall them if already in commerce or provide compelling evidence that product produced before day 7 was not adulterated. For a product sample that tests positive for Lm, inspection personnel will verify that the product lots affected are disposed properly, i.e., destroyed or reworked with a process that is destructive to Lm. Establishments should have supporting documentation that products lots produced before Day 7 are not contaminated with Lm, so that these lots will not be included as adulterated. A product that is positive for Listeria spp. may be considered adulterated if it was produced under insanitary conditions, see Section 3.6.", "FSIS Listeria Guideline January 2014 134 Appendix 4.3: Listeria Trends Examples The following are some scenarios describing how establishments can track and address Listeria trends. Establishment A Establishment A makes RTE salads, including potato salad, chicken salad, and ham salad for delicatessens in grocery stores. The establishment manufactures product in two 8-hour shifts, 6 days a week. The third shift is reserved for sanitation. It has identified three tiers in its sampling program: NFCS sampling, FCS sampling, and finished product testing. It has identified 30 NFCS sampling sites, including the walls next to the preparation tables, the exterior of the mixing kettles, the mixer shaft, and the drains under the preparation tables. Each week it randomly picks 15 of the 30 sites for testing for Listeria spp.; these 15 sites are tested twice a week ("routine monitoring") before production. Results are tracked as total number of positives over time and also by site. When a positive is detected at any site, it is given extra attention during the next sanitation. If the number of positives exceeds 10% (e.g., if there are 3 positives out of 30) during the week (two test periods, rolling window) or if the same NFCS site comes up positive more than one time in a month, these sites are given extra attention during the next sanitation shift, and the areas are re-swabbed daily until there are three consecutive days of negatives. Once this has occurred, the establishment reverts to routine monitoring. If the problem is not corrected within 5 days, the establishment enters "\u201ctrouble shooting\" mode, which includes more stringent decontamination procedures, such as disassembly and sanitizing, fogging with sanitizers, changing sanitizers, double sanitizing, and heat treatments. Establishment A also conducts routine random FCS testing and it has identified 20 FCSs, including tables, conveyor belts, and slicer blades. Each week, 10 of these are randomly selected and tested for Listeria spp., twice per week at the end of production and before cleaning. If a positive is detected, the site is given extra attention during the next sanitation shift and a follow-up sample is collected. The site is tested daily for 5 days. If the site is positive during this 5-day period, the line is shut down and, if appropriate, torn apart, taking troubleshooting swabs during the disassembly. The product contact surface and

surrounding areas receive extra sanitation and the line is re-assembled. FCS swabs are then taken every two hours during production and all products are placed on hold. If any swab tests positive, product from the 2-hour time period and from each period on either side is tested for Lm. Product that is negative is released. Product that tests positive is destroyed, since re-processing is not an option for this product. The establishment conducts random product testing of one salad product each month by taking one package every two hours from an 8-hour shift and compositing product from two packages. The product is tested for Lm. Product found to be positive for Lm is destroyed and intensified sampling of FCSs for Listeria spp. is conducted daily for a week. If positive FCS results are found, the establishment undertakes investigations to determine the cause of the problem. The Listeria Control Program is also reviewed and revised, as appropriate. Establishment B produces fully cooked, breaded chicken products. The establishment manufactures product on three separate lines in two 8-hour shifts, 6 days a week. The third shift is reserved for sanitation. The establishment's NFCS monitoring component of its Lm Control", "FSIS Listeria Guideline January 2014 135 Program targets the area where product exits the fryer, is chilled, and then packaged. There are two parts to this establishment's program: product contact surface testing and non-product contact surface testing. The establishment monitors 20 NFCSSs on a weekly basis for Listeria spp. (routine monitoring). For each line, 5 swabs are composited, resulting in 4 tests per line for a shift. If a positive is detected, the establishment investigates by re-swabbing and testing the swabs individually, as well as by taking additional swabs in the area. If there are no additional positives, the establishment considers the initial positive to be an isolated incident and returns to routine monitoring. If additional positives are detected, the establishment institutes corrective actions, which may include a review of the current Listeria Control Program, revising GMPs, changing sanitizers, enhanced sanitation in clean areas, and employee retraining. The establishment then monitors twice a week (enhanced monitoring) until there are 4 consecutive negative periods, at which point the establishment returns to routine monitoring. The establishment also monitors 15 FCSs on each line during each shift of production every other week. If the swabs are all negative, it continues routine monitoring. If there is a positive result, the establishment investigates by collecting a follow-up sample of the area, as well as by taking additional swabs in the surrounding area. In addition, it institutes corrective actions, which may include intensified cleaning and changing sanitizers. The establishment then takes swabs to confirm that the actions taken have been effective. If there are no positives, the establishment returns to routine monitoring. If there are any positives, the establishment escalates its corrective actions, which may include intensified testing, breaking down pieces of equipment and sanitizing, and heating pieces of equipment. It would also evaluate the need to conduct finished product testing based on all the existing evidence.", "FSIS Listeria Guideline January 2014 136 Example Table for Tracking Microbiological Sampling Trends This table provides an example spread sheet that establishments may use to track testing results and corrective actions for Listeria spp. over time. Tracking this information will assist establishments in identifying trends and determining whether they are taking the appropriate corrective actions in response to positives and in reaction to trends. In the scenario below, a positive testing result was found on the freezer fan and addressed by the establishment. No trend was identified because it was the first positive found in that area. However, positives continued to be found in the same general area (Line 4 freezer) leading up to a food contact surface (FCS) positive on the

belt exiting the freezer, despite progressively intensified corrective actions taken by the establishment. Negative results seen after the establishment identified a trend and took corrective action (including 3 negatives on the belt exiting the freezer) indicate that the trend was addressed. Corrective actions listed below are only examples and should not be considered the only methods to address Listeria spp. contamination. Regulatory testing for FCSs and non-regulatory testing of NFCS are shown within the table. NOTE: Establishments are NOT required to perform NFCS testing or follow-up testing in response to NFCS positives. These FSAs are performed along with routine risk-based Lm (RLm) sampling. FSIS also performs \u201cfor cause\u201d

FSAs along with Intensified Verification Testing (IVT). The purpose of the FSA is to evaluate the food safety systems (including the HACCP plan and Sanitation SOP) at the establishment to determine if they are effective in controlling the safety of the product. FSAs are performed according to FSIS Directive 5100.1 Enforcement, Investigations, and Analysis Officer (EIAO) Food Safety Assessment Methodology. FSIS reviewed the findings from for cause FSAs performed in response to IVTs on a quarterly basis. FSIS is planning to review the findings in routine FSAs performed during RLms and to include the results of those analyses in future issuances of this guidance. The findings from these reviews are used to help develop new policy and revise current policy to ensure that establishments are meeting the requirements of the Listeria Rule. By summarizing the findings FSA reports, FSIS can provide information to RTE establishments so that they can focus their attention on areas where further improvements in their food-safety systems may be needed. During the FSA review, it was found that several of the establishments had deficiencies in their Sanitation and HACCP design and record keeping systems. These problems included the following:

- \u2022 The establishment failed to follow written Listeria programs. According the Listeria Rule, establishments in Alt. 2b and 3 are required to indicate their sampling frequency and explain why the frequency they have identified is sufficient to control Lm or an indicator organism. As described in the Listeria Guideline, establishments can document the sampling frequency they have identified as part of the Listeria Control Program (Section 3.1). Once the establishment has established a frequency as part of its program, it would need to follow the sampling frequency. If an establishment does not follow the sampling frequency by not collecting a sample during the timeframe specified in their program, it would be found to be non-compliant, unless it can provide other supporting documentation demonstrating that its process is safe.
- \u2022 The establishment did not perform monitoring at frequencies specified in the HACCP plan. In some cases, establishments identified a certain frequency for monitoring the CCPs associated with RTE products (e.g., measuring lethality temperatures) and did not monitor the temperature at the specified frequency. By failing to monitor the CCPs at the specified frequency, the establishment could miss processing deviations that could occur, leading to under processing or other safety issues in the product.
- \u2022 The establishments did not document corrective actions sufficiently. If a deviation occurs from a critical limit, establishments are required to take corrective actions to bring the process under control (9 CFR 417.3). These corrective actions must include measures to prevent recurrence of the deviations. In some cases, the corrective actions written by the establishments did not provide sufficient explanation to demonstrate how future deviations would be prevented.
- ," "FSIS Listeria Guideline January 2014 140
- \u2022 The establishment did not provide supporting documentation for their PLT and AMAPs. In some cases, establishments did not support that their PLTs achieved at least a 1-log reduction of Lm in the product or that the AMAP allowed no more than 2-logs growth of Lm over the shelf-life of the product. The Listeria Guideline provides specific guidance establishments can use to ensure that the supporting documentation for the PLT and AMAP is sufficient and reflects the critical operational parameters of their process (see Appendix 2.1).
- \u2022 The establishment failed to maintain sanitary operations and failed to maintain equipment and utensils in a sanitary manner. In some cases, positive results were found during the RLm or IVT, indicating that sanitary operations were not maintained or that equipment and utensils were not maintained in a sanitary manner. In one case, condensation was dripping directly on exposed-RTE product.

The Listeria Guideline provides information establishments can use to ensure that sanitary operations are maintained (see Appendix 2.2). In addition, establishments can use verification testing to ensure that their food-contact surfaces are sanitary and free of Lm. By collecting samples of non food contact surfaces, establishments can find potential harborage points and address them before the product becomes contaminated. Establishments are required, according to 9 CFR 416.2 (b), to ensure that the facility and the equipment are sanitary and in good repair, so that potential sources of cross contamination, such as condensation, are minimized. \u2022 The establishment did not identify the location and the sites that will be sampled for testing of food contact surfaces in the post-lethality processing environment and provide an explanation of why the testing frequency was sufficient to ensure that effective control of Lm or of indicator organisms is maintained. If an establishment chooses either Alt. 2b or 3, it must test FCSs in the post-lethality processing environment, identify the frequency for testing, and provide an explanation of why the testing frequency is sufficient to ensure the effective control of Lm or indicator organisms (9 CFR 430.4(b)(2)(iii)(A), (C), and (E) and 430.4(b)(3)(i)(A), (C), and (E)). The FSIS expectation is that establishments in Alt. 2b or 3 will identify all possible FCS for testing. The Listeria Guideline provides information on site selection and a list of possible FCSs and NFCSSs the establishment could sample (see Appendix 3.1). Recommended minimum testing frequencies are also provided in the Listeria Guideline (see Section 3.3). Establishments can use the recommended frequencies or select their own frequency; however they would need to provide support that the level of testing is sufficient to demonstrate that Lm is controlled in the product. Establishments should increase their sampling frequency due to repeated positive results, construction, or sanitation issues. \u2022 The establishment did not address hazards reasonably likely to occur in the production process. Some establishments did not list all of the steps in the processing of their product in their flow chart, as required by 9 CFR 417.2(a)(2). In some cases, the establishment did not", "FSIS Listeria Guideline January 2014 141 consider possible hazards from ingredients (such as spices) added after the lethality treatment. In other cases, the establishment did not have supporting documentation on file, such as letters of guarantee or certificates of analysis (COA) demonstrating that each lot of ingredients it added to product were safe and would not cause the product to become adulterated. Information on ensuring the safety of ingredients in RTE product can be found in the FSIS RTE Salmonella Guideline. Information on avoiding sources of environmental contamination can be found in the Listeria Guideline (see Appendix 2.2). By reviewing the examples provided above and addressing deficiencies in their food-safety programs, establishments can help ensure that they meet the requirements of the Listeria Rule. In addition, by reviewing their programs to ensure that possible weaknesses are addressed, establishments can produce safe products and help protect public health.", "FSIS Listeria Guideline January 2014 142 Appendix 4.5: FSIS Response to Comments FSIS received 2 comments in response to the September 2012 \u201cFSIS Compliance Guideline: Controlling Listeria monocytogenes in Post-lethality Exposed Ready-to-Eat Meat and Poultry Products\u201d (FSIS Listeria Guideline). Comment summaries and Agency responses follow. Comment: One commenter questioned why the FSIS Listeria Guideline was revised using only FSIS data and input. The commenter stated that the meat and poultry industry likely would have been able to provide additional assistance or guidance in advance of the draft being issued to field personnel. According to the commenter, revising the guideline after it is has already

been adopted may lead to confusion among the industry or FSIS field personnel. The commenter also stated that collaboration of industry and Agency efforts has lead to a decrease in positives from the FSIS RTE sampling program. Response: As FSIS has done with all guidance documents it has issued in recent years, FSIS sought industry input by seeking comment on the guidance. This practice has allowed FSIS to incorporate comments and feedback from industry and other interested parties. FSIS now adds a message to all draft compliance guidelines stating that the guideline represents FSIS\u2019s current thinking on the topic and should be considered usable as of its issuance. FSIS will routinely update guidance documents to reflect the most current information available to FSIS and its stakeholders. FSIS agrees that the success of the Listeria regulation has been the affect of efforts from industry and FSIS to control contamination of RTE products. This information has been added to the Introduction section of the revised FSIS Listeria guideline. Comment: One commenter stated that the Constituent Update article, issued on September 21, 2012, announcing the availability of the guidance and the instructions in FSIS Notice 59-12, implied that the guidelines should be considered requirements rather than recommendations to industry. Similarly, the commenter stated that instructions in FSIS Notice 59-12 stating that EIAOs are to review the information in the guideline as part of their preparation for performing FSAs, implies that that the guidelines are requirements. Response: As FSIS has stated in explaining the purpose of the FSIS Listeria Guideline, \u201cThis document provides guidance to assist establishments in meeting FSIS regulations. Guidance represents best practice recommendations by FSIS based on the best scientific and practical considerations and does not represent requirements that must be met.\u201d While it is true that the guidance can be used to assist establishments in strengthening their food-safety programs, the guidance does not represent requirements. The purpose section of the guideline has been revised to clarify that establishments may choose to adopt different procedures than those outlined in the guideline, but they would need to support why those procedures are effective in controlling hazards from Lm in RTE products. By using the recommendations in the guideline, establishments would not need to provide further support for their procedures. In FSIS Notice 59-12, FSIS instructed EIAOs not to recommend that IPP issue NRs based on establishments using previous versions of the guidelines. The purpose of this instruction is to ensure that EIAOs do not interpret the guidance as requirements, and that NRs should not be issued to establishments that fail to adopt the most recent version of the guidelines. However, EIAOs may still recommend the issuance of NRs if the establishment fails to support the efficacy of its food safety system to control pathogens. Comment: One commenter requested more information on compositing samples, including information on the pros and cons of compositing samples for both environmental and", "FSIS Listeria Guideline January 2014 143 food contact surfaces. The commenter also suggested that FSIS include provisions for the use of surrogate or indicator organisms for testing purposes in the compliance guideline. Response: FSIS added new information regarding compositing of samples and laboratory methods for analyzing the samples in Appendix 3.3, Sample Collection and Testing Methods. In addition, this section includes information on the pros and cons of compositing the samples. As stated in Appendix 3.3, establishments may choose to test for Lm, Listeria spp., or Listeria-like organisms (LLO). Listeria spp. and LLO are examples of indicator organisms for which establishments may test in lieu of testing for Lm. A finding of Listeria spp. or LLO on a food contact surface could indicate conditions where Lm could survive. FSIS has also

provided examples of the use of non-pathogenic Escherichia coli (E. coli) cultures as surrogate indicator organisms in validation studies in the following Q&A: Use of Non-pathogenic Escherichia coli (E. coli) Cultures as Surrogate Indicator Organisms in Validation Studies. As FSIS continues to revise its guidelines and to issue new guidelines, it plans to provide more information about surrogate and indicator organisms that can be used for in-plant validation studies. Comment: One commenter suggested that FSIS provide assistance to small and very small establishments concerning the changes in the guidelines by performing outreach in the form of webinars, resource documents, regional meetings, and any other form of education the Agency can provide to those establishments. Response: FSIS agrees that it would be worthwhile to conduct outreach to small and very small establishments regarding the changes in the guidelines. FSIS is planning to present a series of webinars describing the changes.

Establishments may also submit specific questions through AskFSIS, and subject matter experts will respond to their questions. Comment: One commenter asked about the use of different values in the examples and tables, the definition of \u201ccook-in bag\u201d product, and the use of Safe Handling Instructions (SHI) on RTE product. Response: With regard to the values in Table 2.1 and the values in the examples, the values in the table would be effective if used alone to control Lm growth. However, the values in Example 1 in Section 2.1 are different than the values in Table 2.1 because of the \u201churdle effect,\u201d which is the synergistic effect of parameters to control Listeria growth. FSIS revised the examples in the guideline to more clearly describe the impact of multiple factors on pathogen growth and provided a new section on the hurdle effect. In addition, FSIS revised Appendix 1.1, Product types, to further clarify that cook-in bag products are not considered deli products because they are not subject to the Listeria Rule. FSIS also revised Attachment 1.2, Chart of RTE vs. NRTE Products: Resource 1, to clarify when SHI are required and

recommended."],{"file\_name":"FSIS\_GD\_2014\_0002","title":"Generic Label Approval","num":"FSIS-GD-2014-0002","id":"8d4f0b2eed14d17170513b5ca33368afbbe76928971b391febc51d1f28c36551","corpus":"fsis\_guidelines","source\_page\_url":"https://www.fsis.usda.gov/policy/fsis-guidelines","url":"https://www.fsis.usda.gov/sites/default/files/media\_file/2021-02/Generic-Final-Rule-Overview-

Industry.pdf","type":"pdf","n\_pages":50,"word\_count":3243,"text\_by\_page":[{"FSIS Labeling and Program Delivery Staff (LPDS) January 14, 2014","The Federal Meat Inspection Act (FMIA) and Poultry Products Inspection Act (PPIA) require food manufacturers to obtain prior approval for labels of meat and poultry products before products may be marketed. Prior approval is granted one of two ways: Sketch approval which is approved by the Labeling and Program Delivery Staff (LPDS). Generic approval which is approved by being in compliance with applicable regulations. 2, "The Label review process by Labeling and Program Delivery Staff (LPDS). May be a printer's proof or equivalent that is sufficiently legible to clearly show all labeling features, size, and location. May be hand drawn, computer generated, or other reasonable facsimiles that clearly reflects and projects the final version of the label. Certain types of labels require sketch approval (discussed later in this presentation). 3, "Sketch approved labels reviewed by LPDS are either approved or modified. A sketch label is the concept of a label while a final label is the label that is applied to

product before distribution in commerce. Establishments are responsible for ensuring final labels applied to product are in compliance with FSIS regulations 4", "FSIS regulations approve some labels generically Generic labeling approval refers to the approval of labeling or modifications to labeling prior approved by the Agency without submitting such labeling to FSIS for sketch approval Generic labeling approval requires that all mandatory labeling features are in conformance with FSIS regulations Although such labeling is not submitted to FSIS for approval, generically approved labels are approved by being in compliance with applicable regulations, therefore Generically approved labels applied to product are consistent with the Agency's prior labeling approval system

NOTE: FSIS Inspectors do not generically approve labels. Establishments do not generically approve labels. FSIS approves labels through generic labeling regulations.

5", "By regulation, FSIS specified when a generic approval could be undertaken by an establishment (9 CFR 317.5 and 381.133) Generic approval forgoes the need to obtain sketch approval

Prior to the new rule specific labels were eligible for generic approval AND

certain changes could be made generically to sketch approved labels 6", "On November 7, 2013, FSIS published a final rule that amended the meat and poultry products inspection regulations to expand the circumstances under which the labels of meat and poultry products would be deemed to be generically approved by the Agency Effective January 2014, four categories of labels now REQUIRE sketch approval ALL OTHER labels that do not fit into one of the four categories do not require sketch approval by LPDS

7", "Final rule amended FSIS regulations to combine the previous regulations that provided for labeling approval (9 CFR 317.4 and 381.132) and generically approved labeling (9 CFR 317.5 and 381.133) for meat and poultry products into one new section New label approval regulations for meat and poultry products now in 9 CFR 412.1; approval of generic labels now in 9 CFR 412.2

8", "Only certain types of labeling require submission for evaluation by LPDS

Temporary labels for temporary approval (9 CFR 412.1(c)(4))

Labels for products produced under religious exemption (9 CFR 412.1(c)(1))

Labels for products for export with labeling deviations (9 CFR 412.1(c)(2))

Labels with special statements and claims (9 CFR 412.1(c)(3))

FSIS will continue to require the submission of such labels because they are more likely to present significant policy issues that have health or economic significance

9", "New Generic Labeling Final Rule introduces the four categories of labels that require prior approval by LPDS:

Temporary labels Religious exemption Exports with labeling deviations Special statements and claims

10", "A temporary label approval may be granted for labels with a regulatory deviation that does not pose any potential health, safety, or dietary problems to the consumer Approval not to exceed 180 days

Temporary label approval granted on a caseby-case basis

11", "Approval process unchanged by the new generic labeling rule

FSIS assesses the public health risk and potential economic adulteration when deciding to grant approval for the use of a temporary label

The regulations are not specific enough to assist establishments in determining when a temporary label may be granted

For these reasons, FSIS is not expanding the scope of generic labeling approval to include temporary label approvals and extensions.

12", "Religious-exempt product (poultry) does not receive the mark of inspection and, therefore, deviates from the general labeling requirements for meat and poultry products

Labels for religious-exempt

product must be submitted to LPDS for sketch approval \uf0d8 Ritually-slaughtered meat and poultry products receive the mark of inspection (Kosher, Halal) and may be approved generically provided that they don\u2019t meet one of the other labeling categories requiring sketch approval 13","\uf0d8 Exports of U.S. meat and poultry products occur under agreements between the U.S. government and foreign governments \uf0d8 Agreements require U.S. government approval of labels on meat and poultry products to be exported bearing labeling deviations \uf0d8 Includes ensuring that any changes made to labels on meat and poultry products are allowed per the importing country\u2019s laws (9 CFR 317.7 and 381.128) \uf0d8 Labels marked \u201cfor export only\u201d that bear labeling deviations and therefore cannot be used domestically must be sketch approved by LPDS 14","\uf0d8Detailed list of special statements and claims requiring LPDS approval and examples of claims eligible for generic approval is available on FSIS website <http://www.fsis.usda.gov/wps/wcm/connect/bf170761-33e3-4a2d-8f86-940c2698e2c5/Comp-GuideLabeling-Evaluation-Approval.pdf?MOD=AJPERES> \uf0d8List includes commonly used special statements and claims 15","Examples of special statements and claims: o3rd party raising claims or programs (i.e. Global Animal partnership, AMS Process verified or certified programs, American Heart Association (AHA) claims) oClaims regarding meat and poultry production practices (i.e. claims regarding the raising of animals such as \u201cno antibiotics administered\u201d or \u201cvegetarian fed\u201d) oBreed claims (Berkshire, Angus, Hereford, etc) oCertified claims, Certified Halal oGluten free: both certified and non certified oHealth claims defined in 21 CFR Subpart E, e.g. dietary saturated fat and cholesterol and risk of coronary heart disease (21 CFR 101.75) 16","oImplied Nutrition Claims for example Heart Smart, Baked Not Fried, Made without Butter oStatements that identify a product as \u201corganic\u201d or containing organic ingredients oInstructional or disclaimer statements concerning pathogens, such as \u201cfor cooking only\u201d; \u201cnot tested for E. coli O157:H7\u201d; or \u201cFor high pressure pasteurization at establishment ABC\u201d oNatural claims, e.g. \u201cAll Natural\u201d, \u201c100% Natural\u201d oNegative claims or \u201cfree\u201d claims (no MSG, no MSG added, no preservatives) 17","oOmega 3 factual statements o\u201cWhole Grain\u201d, \u201cMade with Whole Grains\u201d, \u201cMade with whole wheat\u201d claims oNutritional Front of Pack statements, for example \u201c0 grams trans fat per serving\u201d, Nutrition facts Up Front oClaims of the use of non-genetically engineered ingredients oClaims that are undefined in FSIS regulations or the Food Standards and Labeling Policy Book (Note: natural and negative claims are defined in the policy book but will continue to be required to be submitted for approval). 18","19 Special Claim (Breed Claim) Special Claim (Natural Claim)", "20 Special Claims (Organic Claims and logo)", "\uf0d8Some statements and claims are not considered \u201cspecial\u201d under 9 CFR 412.1 (e), e.g. statements of fact \uf0d8Statements and claims of this type may be approved generically (9 CFR 412.2(b)) \uf0d8The next two slides review examples of statements that are not considered special and may be approved generically 21","oAll, 100%, pure oAllergen or \u201cContains (name of ingredient)\u201d statements (e.g., contains soy) oAMS Grading (Prime, choice, grade A) oChild Nutrition Boxes oFlavor Profiles (e.g. made with fennel, teriyaki flavored, made with real cheese, only white meat) oForeign Language on domestic products oGeographic claims (refer to 9 CFR 317.8(b)(1)) 22","oGreen Claims\Environmental Claims oHalal, Kosher (not certified) oHand pulled style\hand pinched style oHandcrafted, handmade, hand slaughtered, hand

Yes. Previously approved labels containing special statements or claims may be generically approved if the modifications to the label are unrelated to the special statement or claim. 40", "May the establishment number be changed generically from one establishment number to another in the case of a label bearing a special statement or claim? For example, may Plant B use an

approved label from Plant A by simply changing the Establishment number from A to B? Yes, this may be permitted under certain circumstances. If Plant B obtains a complete copy of the original label application and all associated supporting documentation necessary to support any special statements or claims on the original application approved for Plant A, then Plant B would have a complete label record on file and would be permitted to change the Est. number from A to B. In this case the information contained within the labeling application would be expected to remain the same (e.g. HACCP category, product formulation, processing procedures). 41", "Labels with negative claims must be submitted to FSIS for approval. How does FSIS define \u201cnegative claims\u201d ? \u201cNegative\u201d labeling claims are defined in the Food Standards and Labeling Policy Book. Negative claims refer to statements highlighting the absence of an ingredient or another constituent of the food, an example of which, \u201cgluten free,\u201d has been codified in 9 CFR 412.1 (e). \u201cNo milk\u201d is another example of a negative claim that highlights the absence of an ingredient or another constituent of a food. A negative claim may also identify the absence of certain types of ingredients e.g. \u201cno preservatives\u201d or \u201cno artificial coloring\u201d based on the product formulation. NOTE: Nutrient content claims (e.g. fat free, cholesterol free) are not considered negative claims under the Policy Book entry. 42", "Is the child nutrition (CN) box on a meat or poultry product considered a special statement or claim and require sketch approval? No. The CN information in CN boxes is reviewed and evaluated for approval by the Agricultural Marketing Service (AMS), removing it from the realm of a special statement or claim. 43", "May statements on labels that are defined in FSIS\u2019s regulations or the Food Standards and Labeling Policy Book be generically approved? With the exceptions of \u201cnatural\u201d and negative claims, yes, defined statements may be approved generically. Examples of such claims that will no longer require sketch approval by FSIS include: \u25e6A statement that characterizes a product\u2019s nutrient content that is consistent with the applicable Agency regulations, such as \u201clow fat\u201d \u25e6Addition of a nutrition facts panel to a product sold at retail \u25e6A statement that has geographical significance, such as \u201cItalian Style\u201d 44", "Do non-standardized products still require LPDS Sketch approval? The fact that a product does not have a standard described in the FSIS Food Standards and Labeling Policy Book or specified in the regulations has no bearing on whether or not the label requires sketch approval. A non-standardized meat or poultry product may be generically approved provided it does not fall into one or more of the four categories of labels requiring approval in 9 CFR 412.1(c): temporary approval, labels for export with labeling deviations, religious exempt, or labels bearing special statements or claims. 45", "Will allergen statements require approval by LPDS staff? No. FSIS will not view the addition of an allergen statement (e.g., \u201ccontains soy\u201d) applied in accordance with the Food Allergen Labeling and Consumer Protection Act (FALCPA) as a special statement or claim that requires sketch approval. 46", "Will labels containing foreign languages on products for sale in the US that do not have special statements or claims require prior approval by LPDS staff? No. While the previous meat and poultry inspection regulations did not permit the generic approval of a label adding or deleting a direct translation of the English language into a foreign language for product sold in the U.S., this final rule will allow it. These types of labels do not fall into any of the categories of labels that must be submitted to FSIS for evaluation and review. 47", "Do front-of-package labeling statements that meet the requirements for nutrient content claims, including statements of quantity,

qualify for generic approval? No. FSIS considers certain front-of-pack (FOP) labeling statements, such as those highlighting select nutrients from the nutrition facts panel placed on the principal display panel, to be nutrient content claims. However, unlike traditional nutrient content claims, such as \u201clow fat,\u201d that are defined in FSIS regulations, there are no guidelines for the multiple types of FOP labeling statements on labeling.<sup>48</sup> "What are the record keeping requirements for generically approved label? Establishments are required to keep records of all labeling, both generically approved and approved by FSIS, along with the product formulation and processing procedures, as prescribed in 9 CFR 320.1(b)(11), 381.175(b)(6), and 412.1. The final rule added the requirement that any additional documentation needed to support that the labels are consistent with the Federal meat and poultry regulations and policies on labeling also be kept.<sup>49</sup>" \u2022 FSIS Labeling Website: <http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatory-compliance/labeling> \u2022 Guide to Federal Food Labeling Requirements for Meat, Poultry and Egg Products: [http://www.fsis.usda.gov/wps/wcm/connect/f4af7c74-2b9f-4484-bb16fd8f9820012d/Labeling\\_Requirements\\_Guide.pdf?MOD=AJPERES](http://www.fsis.usda.gov/wps/wcm/connect/f4af7c74-2b9f-4484-bb16fd8f9820012d/Labeling_Requirements_Guide.pdf?MOD=AJPERES) \u2022 Final Rule: <http://www.fsis.usda.gov/wps/wcm/connect/3b0efaeb-9a81-4532-a1ccb4d1cdb30f4a/2005-0016F.pdf?MOD=AJPERES> \u2022 Questions submitted through askFSIS : <http://askfsis.custhelp.com> \u2022 Call LPDS at (301) 504-0878 50"]}, {"file\_name": "FSIS\_GD\_2014\_0009", "title": "Compliance Guideline for Establishments Sampling Beef Trimmings for Shiga Toxin-Producing Escherichia coli (STEC) Organisms or Virulence Markers", "num": "FSIS-GD-2014-0009", "id": "61f130cb0c103f525b7246e84fbdbcebf6c987f9ed9746da4c720d6c3d214e09", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/import/Compliance-Guide-Est-Sampling-STEC.pdf", "type": "pdf", "n\_pages": 40, "word\_count": 13643, "text\_by\_page": ["August 2014 FSIS Compliance Guideline for Establishments Sampling Beef Trimmings for Shiga Toxin-Producing Escherichia coli (STEC) Organisms or Virulence Markers", "2 Table of Contents & Section Links: I. Appendix 2: FSIS Response to Comments Page 40", "3 Food Safety and Inspection Service (FSIS) developed this compliance guideline to assist beef slaughter\fabrication establishments that perform testing for Shiga toxinproducing Escherichia coli (STEC) organisms (or virulence markers) using the N60 sample collection method on beef manufacturing trimmings. FSIS requires that establishments perform ongoing verification activities to ensure their food safety system is functioning as intended (9 CFR 417.4(2)) and support decisions made in their hazard analysis (9 CFR 417.2 and 417.5(a)(1)). Establishment verification testing results on trimmings are likely the best available objective information a slaughter establishment can use to determine the ongoing effectiveness of its slaughter\fressing operation. Establishments can use the information to support decisions made in their Hazard Analysis and Critical Control Points (HACCP) systems. FSIS recommends that establishments incorporate statistical process control methods to monitor and control the quality of their products."]}]

control procedures into their testing programs. FSIS recommends that establishments use the test results to assess the effectiveness of their controls for preventing contamination during the slaughter operation and verify that they are reducing STEC to a non-detectable level.

Establishment sampling programs can be supplemented with other types of verification activities associated with production of other raw ground beef and patty components. The high event period (HEP) guidance provided in this document applies mainly to beef slaughter\fabrication establishments that manufacture 50,000 pounds or more of trimmings daily. Such establishments are likely to conduct sufficient verification testing on same source materials to be able to determine whether a HEP occurred. This guidance includes some general discussion at the end of Chapter III regarding how smaller establishments may choose to define a HEP. This document also includes general information on verification testing, designing sampling plans, and factors affecting the design of sampling. It also includes examples of sampling methods. These topics are covered in Chapters V through VIII and will apply to establishments of any size. This document also provides general information for non-slaughter establishments that produce or receive trimmings, although non-slaughter establishments will not know if problems with I.Introduction This guidance has been updated to reflect the Agency\u2019s recent policy developments. Since FSIS issued this compliance guideline for comments in May 2012, FSIS began testing beef manufacturing trimmings for six nonO157 STECs (O26, O45, O103, O111, O121, and O145) in addition to E. coli O157:H7. These six non-O157 STECs are capable of producing Shiga toxin (stx) and intimin (eae). FSIS declared these six non-O157 STECs adulterants in raw, non-intact beef products and product components.

(<http://www.fsis.usda.gov/wps/wcm/connect/6aa26172-2d27-4534-99d48c528b285fd2/20100023.pdf?MOD=AJPERES>).", "4 slaughter and dressing procedures have contributed to a HEP situation unless the supplier provides that information as part of a purchase specification program arrangement. This guideline reflects comments received on the Agency\u2019s Draft Compliance Guideline for Establishments Sampling Beef Trimmings for Shiga ToxinProducing Escherichia coli (STEC) Organisms or Virulence Markers issued in May 2012. FSIS has also added an appendix that provides additional information on how FSIS developed its HEP criteria. Finally, this guidance represents current FSIS thinking. It is considered usable now. FSIS will update the guideline as needed to reflect the most current information available to FSIS and stakeholders. This document provides recommendations rather than regulatory requirements. This Compliance Guideline follows the procedures for guidance documents in the Office of Management and Budget\u2019s (OMB) \u201cFinal Bulletin for Agency Good Guidance Practices\u201d (GGP). More information on the bulletin can be found on the FSIS Web page: <http://www.fsis.usda.gov/wps/wcm/connect/fsis-content/internet/footer/policies-and-links/significant-guidance-documents/significant-guidance> ).", "5 HEP are periods in which slaughter establishments experience a high rate of positive results for STEC (or virulence markers) in trim samples from production lots containing the same source materials. That is, the trim was produced from one or more carcasses

slaughtered and dressed consecutively or intermittently within a defined period of time (e.g., shift). A HEP may mean that a systemic breakdown of the slaughter dressing operation has occurred and has created an insanitary condition applicable to all parts of the beef carcass (e.g., primal cuts in addition to the beef manufacturing trimmings and other raw ground beef and patty components). FSIS recommends that establishments identify HEP criteria so that they can

determine whether they need to withhold product from commerce when a HEP has occurred because the presence of a HEP may indicate more widespread adulteration of product, beyond the product found positive. If establishments identify and respond to HEP, they will minimize the chance that they release adulterated product into commerce. This revised guidance recommends two distinct HEP situation criteria: one type for a localized out-of-control situation, and a second type for a systemic breakdown situation. In both situations, FSIS believes that establishments should be concerned if their sampling of trimmings produce a positive rate statistically significantly greater than 5%, rather than 1.5 percent positive, as discussed in the 2008 draft guidance. In such cases the processor should review process control measures and intervention measures used during slaughter, dressing, fabrication, and grinding. The two types of HEP that may indicate out-of-control situations are: 1. A HEP that indicates a localized out-of-control event in which some specific occurrence or event causes a clustering of STEC contamination in product. 2. A HEP that indicates a systemic break-down or inherent weakness of the process or food safety system.

**KEY QUESTION** Question: What is a HEP?

Answer: High event periods (HEP) are periods in which slaughter establishments experience a high rate of positive results for STEC (or virulence markers) in trim samples from production lots containing the same source materials. A HEP situation may mean that a systemic breakdown of the slaughter dressing operation has occurred and has created an insanitary condition applicable to all parts of the beef carcass (e.g., primal cuts in addition to the beef manufacturing trimmings and other raw ground beef and patty components). This is because HEP indicate a more widespread adulteration of product, beyond any product found positive for the pathogen. By following this guidance and withholding adulterated product from commerce during HEP, establishments are more likely able to avoid costly recalls.

II. High Event Periods (HEP)<sup>6</sup>

In both situations, FSIS believes that if an establishment's sampling of trimmings during a period produced a positive rate statistically significantly greater than 5%, there was a severe loss of process control during that period. In such cases, the processor needs to thoroughly review its process control and intervention measures used during slaughter, dressing, fabrication, and grinding. One difference between a systemic break-down and a localized out-of-control situation is the amount of product that should be assessed to determine whether it may be adulterated. A localized out-of-control situation may affect only the production of one lot, while a systemic break-down may affect more products. Also, a localized HEP may indicate an isolated problem (such as improper application of an antimicrobial on one lot); a systemic HEP may indicate a broader problem (systemic failure to prevent cross contamination among carcasses or improper application of antimicrobial on many lots). When either of these trigger criteria is reached, the establishment may determine that production lots of beef manufacturing trimmings containing same source materials that were sampled, tested, and found negative should be considered as having a false negative result, depending on the reason for the HEP. If the establishment makes that determination, such product should be diverted to a full lethality treatment or otherwise destroyed. To develop recommendations for identifying a HEP, FSIS examined industry data collected in 2010 by FSIS inspection personnel from the top 33 slaughter establishments, based on production volume (heads slaughtered). Of the 33 establishments, 32 responses were received, 19 had clear definitions of a HEP, 2 had clear but incomplete definitions because they did not specify a time frame (which FSIS interpreted to be a day), 10 had unclear definitions of a HEP, and 1 did not

have a definition. Of the 21 establishments that had clear definitions (including the two FSIS interpreted), 7 were using a 5% threshold definition; there were 3 that had definitions greater than 10%. Based on these results, FSIS selected a target of 5%. That is, FSIS would consider an establishment's process to be within a HEP if the percent positive within a set time (1 day, shift, etc.) is 5% or greater. KEY QUESTION Question: Why should establishments evaluate their test results using HEP criteria? Answer: When establishments experience a HEP, FSIS believes with a high degree of confidence of poor processing or poor food safety controls. Therefore, establishments need to take extraordinary action to ensure that adulterated product does not enter commerce." "7 FSIS would not consider the establishment's process within a high event period if the percent positive is less than 5% within a given time period. FSIS developed its HEP criteria using a very high degree of statistical confidence. That way, FSIS has a very high degree of confidence that the process's percent positive truly exceeds 5%. FSIS did not select a lower target because it did not want to define HEP criteria that would be as, or more, rigorous than those of a large number of establishments. FSIS did not select a higher target (e.g., 10%) because the Agency believes such a target could result in many cases where poor processing, as defined by most of the industry, would not be detected as a HEP. The HEP criteria FSIS has provided in this guidance indicate exceptional events of poor processing. FSIS would consider an establishment's process to be within a HEP if, during the period of sampling, the (true) process percentage of positive is not less than 5%. To avoid incorrectly saying a HEP occurred, FSIS required a specified degree of statistical confidence before asserting a HEP occurred. More detailed information on how FSIS developed its HEP criteria can be found in Appendix 1: Detailed Explanation of FSIS's HEP Criteria. Industry typically makes decisions to identify HEP based on presumptive positive results (or what FSIS terms potential positive results) from initial screening tests that produce a high percentage of false positives.<sup>1</sup> Percentages of presumptive positive results are greater than percentages of confirmed results. FSIS identified a target that was in accordance with today's present industry standard. Most establishment testing methods include an enrichment step followed by differential screening specific to STEC or their virulence markers. Positive results during screening tests require further testing to detect STEC. If the establishment does not perform further testing, it should treat positive screen results as confirmed positives. FSIS considers those results positive for STEC. FSIS recognizes that many establishments test for other STEC or their associated virulence markers and treat those positive screen results as positive for STEC. Establishments can apply the guidance in this document to such positive screen results. Therefore, this document refers to E. coli O157:H7 and the six non-O157 STECs as *\u201cSTEC\u201d* and positive screening tests for STEC virulence markers. The 2008 guidance specified that an E. coli O157:H7 percent positive of greater than 1.5%, for samples collected using the N60 collection method, indicated that 1 The FSIS analysis for the presence of E. coli O157:H7 has two screening stages before confirmation. See MLG 5A.02 (10\01\10). Also see: [http://www.fsis.usda.gov/wps/wcm/connect/316b1e53-beba-4f2b-971ab587fe4744e2/MLg\\_5A\\_02.pdf?MOD=AJPERES](http://www.fsis.usda.gov/wps/wcm/connect/316b1e53-beba-4f2b-971ab587fe4744e2/MLg_5A_02.pdf?MOD=AJPERES) for a flow chart of FSIS's procedures." "8 a process may be out of control and thus in a HEP situation. Based on that percent positive, the prior guidance recommended that four positive E. coli O157:H7 results out of 91 consecutive N60 samples should be seen as indicating a loss of control. FSIS changed the recommended target from the value given in its 2008 draft guidance of 1.5% positive to 5%

positive. FSIS made this change for two primary reasons. First, FSIS recognizes that many establishments treat a potential or presumptive positive sample result as if the sample was confirmed to contain viable E. coli O157:H7. These practices result in a higher positive rate than that seen for FSIS verification testing that is specifically for viable E. coli O157:H7 that have been confirmed positive. Second, FSIS made this change to a higher target value to increase confidence that an insanitary condition likely occurred during the slaughter\ dressing operation. With a greater target value that the process is statistically significantly greater than 5%, the establishment and the Agency would have greater confidence that the food safety system is truly out of control for many situations with an identifiable cause than compared to its confidence when using a target of 1.5%. FSIS does not expect such HEP situations to happen often during any 12-month period when an establishment\u2019s slaughter dressing operation is properly functioning. FSIS did not want to recommend HEP criteria for establishments unless it can be highly confident that there are identifiable factors that contributed to the high percentage of found positive results. Establishments may choose to use the earlier guidance based on 1.5%. As is discussed below, establishments may choose to develop stricter HEP criteria than FSIS is recommending. By choosing the stricter HEP criteria, the establishment reduces its vulnerability for releasing product into commerce that could test positive at a subsequent point in processing or that could be associated with illness. Establishments should be able to support whatever HEP criteria they use. HEP criteria are most useful to establishments that have rigorous testing programs. FSIS recommends that slaughter\fabrication establishments conduct sampling and testing of trim at a frequency sufficient to find evidence of contamination surviving the slaughter and dressing operation (optimally every production lot) in an effort to ensure that adulterated product does not enter commerce. Microbiological testing is necessary because not all contamination can be seen with the naked eye. It is also important to detect all contamination because high levels of contamination may significantly reduce the safety margin afforded by antimicrobial treatments. Establishments grouping five combo bins of trimmings into production lots represented by one N60 sample may be less capable of discerning a HEP situation than establishments that collect an N60 sample from a one combo bin production lot. However, establishments that group multiple combo bins into a production lot may have a scientific basis for selecting samples or grouping samples that allows them to identify a HEP effectively; they may have had a contract study conducted for them based on their own in-plant conditions that supports their lotting practices and shows that their sampling and testing has a high probability of detecting positives when present. In addition, establishments that exclude exterior fatty trimmings from calculation of a HEP situation may be less capable of identifying a HEP situation. Additional assistance and information on these matters can be found in publications of the Beef Industry Food Safety Council, at: <http://www.bifsc.org/groundbeef.aspx> For the purpose of this document there are two types of a HEP that may indicate out-of-control situations: 1. A HEP that indicates a localized out-of-control event in which some specific occurrence or event causes a clustering of STEC contamination in product. 2. A HEP that indicates a systemic breakdown or inherent weakness of the process or food safety system. FSIS recommends that

establishments evaluate their testing results for both short term (local) and long term (systemic) periods for which the positive rate is substantially greater than that expected or typically observed within production days or shifts. Establishments can evaluate their processes during both periods by applying a set of criteria within different moving windows of testing results. If the establishment exceeds one of the HEP criteria, FSIS believes there is a high degree of confidence that particular events occurred that indicates poor processing or poor food safety controls. Below are criteria establishments may use for determining whether they have experienced a HEP.

1. For a local HEP: 3 or more STEC (or virulence markers) positive results out of 10 consecutive samples from production lots containing same source materials; that is, the trim was produced from one or more", "10 carcasses slaughtered and dressed consecutively or intermittently within a defined period of time (e.g., shift); and

2. For a systemic HEP:

- a. 7 or more STEC (or virulence markers) positive results out of 30 consecutive samples from production lots containing same source materials.
- b. Establishments that test more than 60 samples per day from production lots containing same source materials can use Table 1 below for determining criteria for a systemic HEP. Table 1 provides, for a given number of samples (window) the number of positive results that would provide close to 99% confidence that the establishment\u2019s process percentage of positive results during the period of sampling exceeds 5%. The criteria in Table 1 apply for local HEP and for systemic HEP that apply for a day (or shift) of processing (2b above). The numbers of positive results within these windows, if obtained, provide high degrees of confidence that the establishment has poor processing or poor food safety controls. The moving window method of monitoring process control is a simple and useful tracking procedure. FSIS also is recommending a HEP sample criterion based on obtaining 7 or more positive results within any 30 consecutive samples from production lots. This criterion provides a greater degree of confidence that the process percentage of positive results exceeded 5% than those for the other criteria. FSIS chose a greater degree of confidence (about 99.95%) because in this situation FSIS believes that the establishments should examine rigorously not only trim product but also other primal and subprimal products. For the other HEP criteria, Table 1 provides numbers that would result in a 99% confidence that the 5% target would have been exceeded. Table 1 also includes the observed percentage of positive samples. The reason the observed percentage of positive results is greater than the 5% target FSIS used to establish HEP is because the HEP criteria are based on a very high degree of statistical confidence that the process\u2019s percentage truly exceeds the KEY QUESTION Question: How did FSIS develop its HEP criteria? Answer: FSIS developed the HEP criteria based on a high degree of statistical confidence that the establishment exceeded 5% positive. For the local HEP criteria, FSIS used close to 99% (98.95%) confidence. For the systemic HEP guidance, FSIS used about 99.95%. FSIS expects that establishments will improve their percent positives over time, and, therefore, FSIS plans to adjust the HEP criteria accordingly. See Appendix 1 for more details.", "11 5% target. Establishments may use this table for their testing programs to determine if they have a HEP, or may develop their own. Table 1: HEP Criteria when Establishment test more than 60 samples per Day or local HEP for 10 consecutive samples

Unacceptable # Positives	Number of Samples	Confidence	Observed Percentage of Positive	3	10
98.8%	30.0%	8	61	98.9%	13.1%

98.9%	8.8%	213	98.9%	8.9%	228
FSIS is not					

providing a tolerance for an acceptable number of STEC (or virulence markers) positives. Rather, FSIS is providing guidance on when the number of positive results within a certain number of samples indicates a HEP occurrence. In such situations, negative-tested production lots are possibly contaminated because they were likely produced under insanitary conditions. The establishment would need to determine whether the lots are releasable. The establishment's specific process positive rate may differ from the rate used to construct the above example. These rates may differ depending on the time of year and increase during high prevalence seasons. Consequently, a specified positive rate for a given establishment at a given time should be identified by indicating that a different positive rate was being achieved consistently and product has low likelihood of being adulterated. However, FSIS would consider an establishment to experience a HEP if it experiences a HEP according to FSIS's criteria regardless KEY QUESTION Question: Is FSIS establishing a tolerance for an acceptable number of STEC (or virulence markers) positives? Answer: No, FSIS is providing criteria that indicate exceptional events of poor processing and require extraordinary action so that adulterated product does not enter commerce.", "12 of the time of year. Further, deviations from previously obtained positive rates should be construed as presumptive evidence that the process is out of control and would warrant investigation to find and eliminate any potential causes for the positive results. As part of their supporting documentation for their hazard analysis, FSIS recommends that establishments document their criteria for identifying a HEP. One example for how establishments might develop their own criteria would be to determine an upper bound (limit) process percent positive and then determine how many actual sample results they will use to show whether they have exceeded that upper bound. FSIS expects that slaughter/fabrication establishments are subjecting 100 percent of production lots of trim to N60 verification testing. In addition, FSIS expects that establishments would have a more rigorous verification testing program during the high prevalence season (from spring into mid-autumn) in order to have greater confidence that increased contamination is not passing through the slaughter/dressing operation into the trim production lots. More rigorous verification testing programs might include more restrictive HEP criteria. In addition, small establishments or those that produce product infrequently might choose a different set of criteria from those provided by FSIS. The end of Chapter III below has specific suggestions. The following tables are provided to help establishments derive parameters for determining whether they have experienced a HEP. The tables provide specified numbers of positive results (first column) occurring within a specified number of samples (entries within the remaining columns) from production lots. Those indicate that the true percent positive of STEC findings (or virulence markers) would be greater than or equal to the specified percent positive given in the column headings, for the following percent confidence intervals: 2 There are other tracking procedures, such as calculating and graphing cumulative sums of differences of results from a specified target (CUSUM) and exponentially weighted moving averages (EWMA), which do not require such determinations. III. Sample HEP Numerical Criteria", "13 with 95 percent confidence (Table 2); close to 99 percent confidence (Table 3); and close to 99.95 percent confidence (Table 4). The latter two tables show how FSIS developed the criteria for localized or systemic HEP. In the tables below, the test result from one composite sample of multiple slices (e.g., N60 sample) is considered one positive or negative result. Table 2: Lower Bounds of Percent Positive, Based on Number of Samples Tested True positive percent of STEC

(or virulence markers) findings is greater than corresponding lower bound percentage in column with 95% confidence, given the number of positive results (rows) within corresponding number of samples (interior table entries) Number Positive 0.50% 0.68% 0.75% 1.0% 1.5% 2.0% 3.0% 3.5% 5.0% 2 71 52 47 35 24 18 12 10 7 3 164 120 109 82 55 41 27 23 16 4 274 201 182 137 91 69 46 39 28 5 395 290 263 198 132 99 66 57 40 6 523 385 349 262 175 131 88 75 53 7 658 484 439 329 220 165 110 95 67 8 797 586 532 399 266 200 134 115 81 9 940 692 627 471 314 236 158 135 95 10 1086 799 725 544 363 273 182 156 110 11 1235 909 824 618 413 310 207 178 125 Based on Table 2, if there were 4 or more positive results within 69 samples, then there would be 95% confidence that the process positive percent exceeds 2%.,"14 Table 3: Lower Bounds of Percent Positive, Based on Number of Samples Tested True positive percent of STEC (or virulence markers) findings is greater than corresponding lower bound percentage in column with about 98.85% confidence, given the number of positive results (rows) within corresponding number of samples (interior table entries) Number Positive 0.50% 0.68% 0.75% 1.0% 1.5% 2.0% 3.0% 3.5% 5.0% 2 32 23 21 16 11 8 5 5 3 3 92 68 62 46 31 23 16 13 10 4 172 127 115 86 58 44 29 25 18 5 266 196 178 133 89 67 45 39 27 6 369 272 247 185 124 93 62 54 38 7 481 354 321 241 161 121 81 70 49 8 598 440 399 300 200 151 101 87 61 9 720 530 481 361 241 181 121 104 74 10 846 623 565 424 283 213 143 123 86 11 976 718 652 489 327 246 164 141 100 Table 4: Lower Bounds of Percent Positive, Based on Number of Samples Tested True positive percent of STEC (or virulence markers) findings is greater than corresponding lower bound percentage in column with about 99.95% confidence, given the number of positive results (rows) within corresponding number of samples (interior table entries). Number Positive 0.50% 0.68% 0.75% 1.0% 1.5% 2.0% 3.0% 3.5% 5.0% 3 32 24 21 16 11 8 6 5 4 4 75 55 50 38 25 19 13 11 8 5 132 97 88 66 45 34 23 20 14 6 200 148 134 101 68 51 35 30 21 7 278 205 186 140 94 71 48 41 30 8 363 268 243 183 123 92 62 54 38 9 455 335 304 229 153 116 78 67 48 10 552 407 369 277 186 140 94 81 58 11 654 482 437 329 220 166 111 96 68 Based on Table 4, if 5 positive results occur within the set of 20 samples, then there is about 99.95% confidence that the positive percent exceeds 3.5%. The establishment may decide that if its percent positive exceeds 3.5%, then the establishment has experienced a HEP. Establishments might have reason to collect a number of samples representing product processed under similar conditions and thus is indicative of the processing during a set period. For example, an establishment might run product","15 during a given time, or for a given day (shift), and take 20 samples of that product. In that case, the tables or similar calculations used for creating the tables can be used for deciding how many positive results within sets of 20 samples would indicate a percent positive greater than that expected. Small establishments that test infrequently might decide to develop other criteria for determining whether they have experienced a HEP. For example, a small slaughter establishment may test 5 samples and find 2 of them positive. For a small establishment that does not test frequently, two positive results (or even 1) might indicate a lack of control in the production of that product and thus could be considered as a HEP. If Tables 2-4 above do not meet an establishment\u2019s needs for determining high event criteria appropriate for the establishment, the establishment should contact askFSIS at <http://askfsis.custhelp.com/> and categorize its question as \u201cSampling\u201d within the system. Through the askFSIS system, establishments can obtain expert advice on the design of HEP criteria. IV. Action in a High Event Period (HEP) In a robust testing program, negative results normally indicate that product may be released in commerce. However, during a HEP,

the establishment needs to consider whether negative-tested lots of trimmings are releasable, and whether primal and subprimal product produced from the same source materials as the trimmings may be positive for STEC. The actions taken in response to a HEP could depend upon the findings of the investigation of the positive results. If slaughter establishments experience a HEP, they should assess what happened during the slaughter and dressing process and take appropriate action that would ensure only unadulterated product is released into commerce. Studies have shown that STEC is present in the hides and intestinal contents of cattle and, therefore, can contaminate the surface of the carcass, trimmings, ground beef, and KEY

**QUESTION** Question: What actions does FSIS recommend in response to HEP? Answer: When a HEP occurs, the establishment needs to consider whether negative-tested lots of trimmings are releasable, and whether primal and subprimal product produced from the same source materials as the trimmings may be positive for STEC. For a local HEP, establishments may not need to sample, test and hold primals and subprimals. However, during systemic HEP, primal and subprimal cuts should be sampled and tested even if treated with an antimicrobial treatment. FSIS recommends that establishments test food contact surfaces for STEC (or virulence markers), and if the surface is found positive consider product that came into contact with those surfaces to be adulterated. IV. Action in a High Event Period", "16 other beef products (e.g., primals, subprimals, and mechanically tenderized or enhanced beef) during slaughter, fabrication, grinding, and processing. The process of removing the hide and intestinal tract requires care, and even under good manufacturing practices, occasional contamination of the carcass meat will occur from direct contact of the hide to the carcass, contact of the hide to equipment, hand-to-hide-to-carcass contact, aerosolization when removing the hide, or puncture of the intestinal tract. Slaughter and dressing procedures should be designed to minimize, to the maximum extent practical, crosscontamination of carcasses with the contaminants from the hide and intestinal tract. As FSIS stated in FSIS PHIS Directive 6410.1, Verifying Sanitary Dressing and Process Control Procedures by Off-Line Inspection Program Personnel (IPP) in Slaughter Operations of Cattle of any Age, the Agency expects that establishments will slaughter and process cattle in a manner designed to prevent contamination from occurring at any step in the process and will use decontamination and antimicrobial intervention treatments as necessary to address any contamination that may result from the implementation of the slaughter process or otherwise occur on the carcasses. If a slaughter establishment believes a HEP has occurred, FSIS recommends that the processor review process control measures and intervention measures used during slaughter, dressing, fabrication, and grinding. Such controls may include measures to reduce the pathogen load on incoming animals, measures to ensure that contamination of the carcass does not occur during slaughter or dressing procedures, decontamination or antimicrobial treatments, and measures to minimize carcass-to-carcass contact and cross contamination. Ensuring and verifying that such controls are indeed working is crucial to preventing future HEP. The actions taken in response to an out-of-control signal could depend upon the findings of the investigation of the positive results. If the establishment finds the cause for the HEP and takes corrective action to prevent positive results from recurring, then an increase in the sampling rate would not be needed. However, the establishment needs to have a high degree of confidence that the corrective actions will be effective before reducing the intensity of its testing. Until such a high degree of confidence is obtained, FSIS recommends that the establishment conduct increased

testing when it experiences a HEP. For example, the establishment could increase sampling rates by either defining smaller lots of trimmings (1 combo bin instead of 5 combo bins) or selecting additional samples from the 5 combo bin lots. During systemic HEP, FSIS recommends that primal and subprimal cuts be sampled and tested, even if treated with an antimicrobial treatment. In addition, during systemic HEP, FSIS recommends that establishments test food contact", "17 surfaces for the presence of STEC (or virulence markers). If they detect the pathogen, establishments should consider product that came into contact with those surfaces to be adulterated. These recommendations are not regulatory requirements. However, by taking these additional steps, establishments will be able to better ensure that they do not release adulterated product into commerce. Therefore, these additional steps may reduce the likelihood of costly recalls. During local HEP, FSIS recognizes that establishments may determine that less product may be affected or implicated by the positive results than in systemic HEP. Establishments may not need to sample, test, or hold primals and subprimals during local HEP. The prevalence of STEC has been greater in cattle coming to slaughter during the warmer months (from spring into mid-autumn \u2013 the \u201chigh prevalence season\u201d) than the colder months. Thus, HEP should be especially anticipated during the high prevalence season. Extra steps should be implemented to increase confidence that contaminated product is not released into commerce for use in raw beef during the high prevalence season compared to the low prevalence season. Such steps could include more frequent monitoring and verification of both slaughter and dressing procedures, additional antimicrobial reduction treatments, or sampling and testing additional product. FSIS also recommends increasing sampling and verification testing during the high prevalence season. During traceback activities, Enforcement, Investigations, and Analysis Officers (EIAOs) will gather information about the production of the product including the use of anti-microbials, prevention of cross-contamination, sanitary conditions, and relevant purchase specifications. Furthermore, as part of their traceback investigations, EIAOs will review slaughter establishment test results to determine whether the establishment has experienced a high event period (HEP).

Establishments are free to develop their own HEP definition as an alternative based on their unique operations. If establishments define HEP differently than FSIS, establishments should support their definition of HEP and provide the information to FSIS during traceback. For purposes of FSIS traceback activities, FSIS will identify HEP events based on the establishment\u2019s HEP criteria, provided the establishment\u2019s criteria is appropriately supported. During FSIS traceback activities, FSIS will evaluate the establishment\u2019s definition and support for defining HEP and determine whether the establishment has taken all affected product into account. If the establishment has not developed its own HEP criteria or its criteria is not supported, EIAOs will determine whether the establishment experienced a HEP based using the guidelines provided in this document. In the event the establishment has not developed or appropriated supported HEP criteria, the specific HEP criteria FSIS will use during traceback are:", "18 1. For a local HEP: 3 or more STEC (or virulence markers) positive results out of 10 consecutive samples from production lots containing same source materials; that is, the trim was produced from one or more carcasses slaughtered and dressed consecutively or intermittently within a defined period of time (e.g., shift); and 2. For a systemic HEP: 7 or more STEC (or virulence markers) positive results out of 30 consecutive samples from production lots containing same source materials. Based on the results of their traceback activities, EIAOs will

make recommendations whether regulatory and enforcement actions are warranted. The District Manager will then determine whether adulterated product entered commerce; if it has, whether to contact the FSIS Recall Management and Technical Analysis Staff; and whether enforcement actions are appropriate. When FSIS requests that establishments recall product, FSIS looks at several factors to determine the scope of a recall, including the establishment's processing and sanitation procedures, and whether there is any finished product reincorporated into fresh product (rework). Why is STEC Verification Testing Important? Because microbial contamination is not visible to the naked eye, microbiological testing is needed to verify that the slaughter and dressing procedures that are designed to prevent microbial contamination are effective. Also, an establishment may incur considerable expense if it becomes necessary to recall contaminated product from commerce<sup>3</sup>. This action becomes necessary when trimmings that have been subjected to antimicrobial interventions are later found positive for STEC or when other production lots from same source materials (i.e., fabricated from a single, common source rather than multiple, commingled sources) are found positive. For these reasons, robust sampling and testing programs that can find product containing STEC can be highly cost-effective. <sup>3</sup> FDA has estimated that a recall can cost government and industry \$3-5 million. (<sup>4</sup> Preliminary Regulatory Impact Analysis and Initial Regulatory Flexibility Analysis of the Proposed Rules to Ensure the Safety of Juice and Juice Products<sup>5</sup> (63 FR 24258; May 1, 1998). The cost covers manufacturer, retailers and State, local, and Federal authorities.

V. General Guidance for Verification Testing of STEC

**KEY QUESTION** Question: Why does FSIS recommend that establishments test beef trimmings for STEC? Answer: Establishment verification testing results on trimmings are likely the best available objective information a slaughter establishment can use to determine the effectiveness of its slaughter/dressing operation.<sup>6</sup> Extensive sampling of trimmings and careful evaluation of test results can help establishments identify areas of poor processing for corrective action. FSIS recommends that establishments continually strive to decrease STEC (or virulence markers) percent positives. FSIS expects establishments that investigate and correct problems will improve processes and decrease percent positives over time. Consequently, FSIS recommends that both slaughter establishments and receiving establishments test source product, including trimmings, for STEC (or virulence markers). FSIS recommends testing finished product even if the source material has been tested and found negative. The reason for this recommendation is that negative test results on samples of product do not imply that product is free of STEC for the following reasons: there may have been pockets of contamination in the product that were not in the actual sample tested at the slaughter establishment, the product might have become contaminated after it was sampled at the slaughter establishment, or STEC (or virulence markers) cells within the actual sample tested might not have been detected at the slaughter establishment because their numbers at the time of testing were below the limit of detection. If a receiving establishment finds incoming product intended for grinding or other raw, non-intact use positive for STEC (or positive in a screening test but not confirmed negative), that product is adulterated, although it may be treated to eliminate the pathogen. The receiving establishment should inform the supplier of the positive test results. For What Organism Should Establishments Test? It is useful to conduct verification testing for associated organisms that include STEC (e.g., a screen methodology for pathogenic STEC) and maintain records of results. Measurements of ubiquitous organisms such as Enterobacteriaceae, aerobic

plate counts (APC),<sup>4</sup> or generic E. coli can be used to evaluate the effectiveness of process controls designed to limit or eliminate microbial contamination. Frequent measurement of APC may capture a short-term trend, which would be useful for quality control, both before and after the sanitary dressing processes. However, such measurements, while helpful for ensuring 4 Measuring the level of APC on pre-eviscerated carcasses might be useful for evaluating the effectiveness of a sampling program and antimicrobial interventions (see T. A. Arthur, et al., 2004, J Food Protection 67(4): 958-665). KEY POINT FSIS recommends that both slaughter establishments and receiving establishments test source product, including trimmings, for STEC (or virulence markers).", "20 microbial process control, cannot be used as a substitute for determining the actual presence or absence of STEC in the final product. The decontamination and antimicrobial treatments applied during the slaughter and dressing operation should be designed to remove, to the maximum extent practical, contamination with pathogens. Each establishment should know the limits of capability of its slaughter and dressing operation for reducing microbial contamination as evidenced by objective data, such as for APC or other indicator organisms of process control on the carcass immediately after hide removal, before the establishment applies any antimicrobial interventions.", "21 KEY QUESTION Question: What is the significance of non-O157 STEC? Answer: The Centers for Disease Control and Prevention (CDC) estimates that there are approximately 175,905 domestically acquired foodborne illnesses associated with all Shiga toxin-producing E. coli (STEC) annually (Scallan et al, 2011)<sup>5</sup>. E. coli O157:H7 is the most well known STEC and, according to the CDC, is annually responsible for approximately 63,153 (36%) of the domestically acquired foodborne STEC illnesses. The remainder of the illnesses associated with STEC (112,752 or 64%) are caused by non-O157 STEC. While more than 50 non-O157 STEC serogroups have been associated with human illness, 70-80 % of confirmed non-O157 STEC illnesses are caused by six STEC serogroups \u2013 O26, O45, O103, O111, O121, and O145. These illnesses can be equivalent in severity to those caused by E. coli O157:H7. In the U.S, at least one outbreak and several sporadic illnesses from non-O157 STEC serogroups have been associated with ground beef products. Many establishments that produce raw, non-intact beef products, such as ground beef, incorporate antimicrobial interventions such as organic acid sprays in their processing. These methods should be effective in controlling non-O157 STEC. However, many firms will want to implement their own testing programs. A prudent establishment would use a test method that includes all hypothetical strains of E. coli O157:H7 and the target non-O157 STEC, either typical or variant organisms with these STECS serotypes, that would be identified using FSIS confirmatory testing procedures and criteria and that increases the likelihood of detecting low level contamination by these pathogens. FSIS recognizes that industry uses non-cultural methods that detect alternative target analytes for STEC including, but not limited to, eae and stx. Establishments may increase the likelihood of detecting all hypothetical strains and low levels of contamination by these pathogens in a variety of ways, including but not limited to using a test method that also is used by a regulatory body or that is validated and certified by an independent body (e.g., AOAC, AFNOR, MicroVal, or NordVal). An establishment may also opt to use a test method that is subjected to a robust validation using the FSIS cultural method as a reference. 5 Scallan E, Hoekstra RM, Angulo FJ, Tauxe RV, Widdowson M-A, Roy SL, Jones JL, and Griffin PM. 2011. Foodborne illness acquired in the United States \u2013 major pathogens. Emerg Infect Dis. 17(1):7-15.", "22 How Frequently Should Establishments Collect a Sample? Sampling and testing

of trimmings for STEC (or virulence markers) should occur at a frequency sufficient to find evidence of contamination (e.g., pathogens) surviving the slaughter and dressing operation. Optimally, every production lot should be sampled and tested before KEY QUESTION Question: Are test kits available to test for STEC? Answer: Several companies have developed or are developing test kits to detect at least the six relevant STEC serogroups. Some kits have been submitted for review by validation bodies. In addition, some kits have been submitted for FSIS review and have received \u201cletters of no objection\u201d from the Agency. FSIS developed guidance for evaluating test kit performance and uses this criteria for evaluating test kits that have been submitted to FSIS for review. FSIS provides a summary table that describes the non-O157 STEC test methods that FSIS has received and reviewed and for which it has issued letters of no objection. The summary table is available on FSIS\u2019s website. FSIS continues to review other test kits submitted for review. For establishment testing or testing on behalf of an establishment, FSIS recognizes that other criteria, while not used specifically by FSIS for identification of a non-O157 STEC, may be a significant and expedient indicator of the presence of non-O157 STEC in products. Such tests might be applied as rapid screening procedures to expedite analyses. If an establishment uses or contracts with a laboratory that uses such rapid screening procedures, and product is found positive by that test, the regulations require the establishment to take appropriate corrective action and to ensure the proper disposition of adulterated products following a positive test result (9 CFR 417.3). The establishment will need to define and support the criteria it uses to define the sampled lot. KEY QUESTION Question: How often does FSIS recommend that slaughter establishments sample and test trim to verify their HACCP system? Answer: FSIS recommends that slaughter\fabrication establishments conduct sampling and testing of trim at a frequency sufficient to find evidence of contamination (e.g., pathogens) surviving the slaughter and dressing operation (optimally every production lot) in an effort to verify and ensure that adulterated product does not enter commerce.", "23 leaving the slaughter establishment and again before use at the receiver. Establishments that do not slaughter but do produce trimmings should report their test results back to the slaughter supplier in order for the supplier to assess the adequacy of its slaughter and dressing practices, as well as antimicrobial treatment programs. Through this feedback, an investigation of the possible reasons for the contamination getting through the slaughter and dressing operation can be conducted and could lead to the identification and correction of possible deficiencies. During the high prevalence season months (from spring into mid-autumn), the frequency of such testing should be increased compared to that of the other months in order to have increased confidence that contamination is not affecting the food safety system. Chapter VI of this document includes information on designing sampling plans. Defining a sampling plan involves establishing the procedures the establishment will use, including how it will collect a sample, the size of the units it will collect, the number of samples it will collect, the frequency with which it will collect samples, and the procedure it will use to analyze samples. What Corrective Actions Should Establishments Take in Response to Positive Test Results? Under 9 CFR 417.3, establishments are required to identify corrective actions in response to every deviation from a critical limit or a deviation not covered by specified corrective action. An STEC positive would fall into one of these two categories that require corrective actions. Corrective actions required in the regulations include identifying and eliminating the cause of the deviation (if STEC are addressed

in the HACCP plan) or reassessing the HACCP plan and determining whether changes to it are necessary (if STEC is not addressed in the HACCP plan). Process control of STEC can be evaluated by tracking past sample results, enabling establishments to tell the difference between an occasional, sporadic, positive result and a loss of process control as indicated by many positive results over time. If past sample results lead establishment management to believe the process is out of control, the establishment should carefully investigate to find all contributing causes. This type of investigation would be more involved than a follow-up investigation when an occasional positive result is found. The finding of an out-of-control process may implicate product in other production lots produced during the period that the process was out of control or from the same source material." "24 How are Corrective Actions Different in Response to a HEP? It is important to note that a HEP situation (localized and systemic) likely means that insanitary conditions occurred during the slaughter\ dressing operation such that contamination is widespread across production lots. When a HEP situation occurs, negative test results from the production lots of trimmings made from the same source materials as trimmings found positive during the HEP may not be reliable. 6 Therefore, those production lots that tested negative may not be microbiologically independent of those directly associated with the HEP. In other words, even though an N60 product sample from a production lot tested negative, trimmings produced from the same source materials as the production lots directly associated with the HEP are also potentially contaminated. When a HEP occurs, establishments should take appropriate precautionary steps to ensure adulterated lots of raw beef are not released into commerce. The establishment specifically needs to consider whether negative-tested lots of trimmings are affected and whether intact primal and subprimal product produced from the same source materials as the trimmings may be positive for STEC. Generally, if primals are not commingled before packaging, and the establishment prevents cross contamination among primals, primals can be considered independent lots. Normally, FSIS does not typically consider primal cuts designated for intact use to be adulterated if contaminated with STEC. During a HEP, however, unless the establishment has controls in place to ensure that the primals are not used for non-intact purposes, such primals may be considered adulterated because they were prepared under insanitary conditions. Establishments that subject primals to an antimicrobial treatment as part of a routine production process may be able to demonstrate 6 The statement does not imply that the usual N60 sampling and testing is not reliable regarding their sensitivity and specificity. However, it is reasonable to assume that during the HEP, the incidence and levels of contamination could be greater than normal. Negative results during a HEP could be resulting from clustered contamination within a lot. Thus, a negative result may not mean that the lot is actually negative. To suggest re-testing product that already tested negative in light of an HEP just means that FSIS is asking establishments to take action to decrease the assumed increased risk that exist in light of the HEP. KEY QUESTION Question: What does the occurrence of a HEP mean? Answer: A HEP likely means that insanitary conditions occurred during the slaughter\ dressing operation such that contamination is widespread across production lots. When a HEP situation occurs, establishments should take appropriate precautionary steps to ensure adulterated product is not released into commerce. The establishment specifically needs to consider whether negative-tested lots of trimmings are affected and whether intact primal and subprimal product produced from the same source materials as the trimmings may

be positive for STEC.", "25 that the primals are not adulterated, provided they have on-going verification testing results to affirm that contamination was not evident. It should be noted that a recent large-scale recall of beef that included primal cuts was associated with a HEP ([http://www.fsis.usda.gov/wps/portal/fsis/topics/recalls-and-public-healthalerts/recall-case-archive/recall-case-archive2009/!ut/p/a1/jZDBC0jAEIafpQdYdlZF9CgLppa7SGS2lxjEdMFUTDz09CmdDKVmTjN8Px8zVNGMqgZHxKg2wbreVb2DRKwmcsKhr7nQyhMP3XEnoG0JC6AFw2A2kiD5yDI8w\\_8xvlwa989IfA6GMel1R1OFREN\\_eWZn2RY12THJ8FwT6v9FisLokB4NILVUsNsKknzckKImGCtL6BIT98gO1Du8c5ex0D0KG3ewMRQGX5/?1dmy&current=true&urile=wcm%3apath%3a%2Ffsis-archivescontent%2Finternet%2Fmain%2Ftopics%2Frecalls-and-public-healthalerts%2Frecall-case-archive%2Farchives%2Fct\\_index286a](http://www.fsis.usda.gov/wps/portal/fsis/topics/recalls-and-public-healthalerts/recall-case-archive/recall-case-archive2009/!ut/p/a1/jZDBC0jAEIafpQdYdlZF9CgLppa7SGS2lxjEdMFUTDz09CmdDKVmTjN8Px8zVNGMqgZHxKg2wbreVb2DRKwmcsKhr7nQyhMP3XEnoG0JC6AFw2A2kiD5yDI8w_8xvlwa989IfA6GMel1R1OFREN_eWZn2RY12THJ8FwT6v9FisLokB4NILVUsNsKknzckKImGCtL6BIT98gO1Du8c5ex0D0KG3ewMRQGX5/?1dmy&current=true&urile=wcm%3apath%3a%2Ffsis-archivescontent%2Finternet%2Fmain%2Ftopics%2Frecalls-and-public-healthalerts%2Frecall-case-archive%2Farchives%2Fct_index286a)). Although all or most trim was diverted to cooking, including trim that tested negative for E. coli O157:H7 (or other STEC organisms or virulence markers), primal cuts that had not been treated with an antimicrobial entered commerce. Illnesses were associated with the trim derived from the untreated primal cuts. How Should Establishments Define Their Lots? Designing a sampling plan involves identifying many factors, including among others, the lot size and the amount of product from each lot that is to be sampled and analyzed. Perhaps the most important step in designing a sampling plan is the definition of a lot of product. The results (positive or negative for the presence of STEC or virulence markers) may determine the disposition of the product within the selected lot and possibly other product as well, depending on how the lots are defined.

VI. Designing Sampling Plans for Verifying Control of STEC

KEY QUESTION Question: In addition to responding to individual positive test results, what does FSIS recommend that establishments use their test results to determine? Answer: FSIS recommends that establishments monitor their test results for two distinct HEP criteria: one for a localized out-of-control situation, and a second for a systemic break-down situation. In both situations, establishments should be concerned if their sampling of trimmings produce a positive rate statistically significantly greater than 5%. "26 Trimmings from each supplier should be tested separately. Limiting product in a lot to that from a single supplier could help decrease the extent of product that would be recalled or sent for cooking when a positive test result is obtained. An establishment should be sure to always define the production lot size before sampling. An establishment should not redefine it during testing or after results are known. Lots should be defined so that if a positive result is found from one lot, the product in other lots is microbiologically independent and is not implicated. FSIS has stated (67 FR 62325; Oct. 7, 2002) that when one lot of trimmings tests positive, lots constructed from the same source material likely would be implicated. FSIS would expect the establishment to have a scientific basis that justifies why any raw ground product produced from those source materials should not be considered to be adulterated (67 FR 62325; Oct. 7, 2002, p. 62333). One way to avoid the results for one lot implicating another is to ensure that the lots are microbiologically independent. The establishment should have a sound basis for defining the lot and is responsible for determining the lot of product represented by the sample. Suggestions for defining microbiologically independent lots:

1. Product from different carcasses can be considered as independent lots provided the meat from the carcasses was handled so as not to crosscontaminate other carcasses.
2. Defining lots based on microbiological testing would be acceptable if the sample collection method is designed to have

a high confidence of detecting positive results when STEC is present in a production lot. 3. Processing interventions that limit or control STEC contamination can help to define the lot. 4. Beef manufacturing trimmings and raw beef components or rework carried over from one production period to another may expand the implicated lot in the event of a positive result. KEY POINT Lots should be defined so that if a positive result is found from one lot, the product in other lots is microbiologically independent and is not implicated." , "27 5. Sanitation Standard Operating Procedures (Sanitation SOP) or any other prerequisite programs used to control the spread of STEC crosscontamination among raw beef components during production can help to define the lot. The following may lead to cross-contamination of raw beef components during production and may expand the implicated lot in the event of a positive result: \u2022 improper sanitary dressing procedures \u2022 insanitary product contact surfaces on equipment, such as machinery and employee hand tools \u2022 improper employee hygiene

What Questions Should Establishments Consider when Designing a Sampling Plan? In designing a sampling plan, an establishment should consider the following questions.

- A. What products are to be tested? Trimmings or other source materials that are supplied to grinders, including cheek meat and head meat (see FSIS Directive 10,010.1)
- B. The size of the lot: what amount of product (i.e., the lot) is to be represented by a sample? The establishment should define how much product is going to be grouped together to constitute a \u201clot\u201d (e.g., combo bins of trimmings; boxes of packaged head meat or cheek meat). Note: FSIS strongly recommends that the lot definition not be redefined. It is unacceptable to change the lot definition based on the results of testing.
- C. How is the sample going to be collected?
  - 1. STEC (or virulence markers), when present, is not evenly distributed throughout a production lot. Therefore, a collection method that selects product at multiple sites within the lot or multiple production intervals within a given lot is more likely to detect pockets of contamination than a sampling plan that samples at fewer sites or production intervals.
  - 2. For trimmings, potential contaminants will be on the exterior surface of the product that was exposed during the slaughter and dressing process. Therefore, collection methods that provide more surface area for the test increase the sensitivity of the sampling (i.e., many thin slices of the exterior exposed fat and lean tissue)." , "28

3. For trimmings, samples can be collected by: \u2022 Obtaining 60 slices from the exterior surface of product within the lot that are as thin as possible resulting in the desired sample size (grams) to be collected. \u2022 \u201cPlug\u201d collection, where product is collected by inserting a specially designed \u201ctube\u201d between pieces of meat so as to excise the trim (exterior areas) of adjacent pieces. This procedure is performed many times, by inserting the tube at randomly selected locations, to ensure that a certain minimum number of exterior surface pieces are collected and achieving the proper weight for the sample. \u2022 Randomly selecting slices of trimmings from trim in combo bins. If the establishment produces several types of trimmings, it should include them all in the sampling program. Trim from exterior surfaces should be prioritized for collection. \u2022 Core drilling, where product is collected at several places in the combo bins by drilling a hole, approximately 25mm in diameter, into surface of meat through a template. The product is thus extracted through a coring tube and can be taken from fresh or frozen trim. \u2022 For frozen trimmings, using a sanitized band saw at 12 points around the edges of a 60-pound frozen block. To make up N60, samples should be collected from five randomly selected frozen blocks. With all these collection methods, specifications should be designed to ensure that a high percentage of the

collected product that is to be used for testing consists of exterior surface tissue. D. How much of the collected product is analyzed? 1. FSIS recommends that the entire sample be analyzed. To accommodate laboratory testing methods that limit the amount of material per analysis, subsamples could be formed and each subsample analyzed in the laboratory. Thus, multiple analyses may be needed. Not analyzing the KEY POINT With all collection methods, specifications should be designed to ensure that a high percentage of the collected product that is to be used for testing consists of exterior surface tissue." "29 entire sample could lead to a significant increase in false negative results (negative results found when the product is actually positive) compared to when the entire amount is analyzed, so that results could be misleading. Laboratory methods used should be effective in detecting the pathogen. NOTE: A sampling plan using the N60 collection method and analyzing a 325375 gram composite sample means that the weight of each of the 60 slices that is \u2018represented\u2019 in the tested material needs to be about 6.25 grams (375 grams\60 slices = 6.25 grams per slice). E. How frequently should establishments test? Optimally, every production lot should be sampled and tested. F. How effective is the testing method? 1. FSIS recommends that the establishment understand and have written documentation regarding how the laboratory is testing the sample, in regard to the size of the sample analyzed and the analytical method that is used. 2. FSIS recommends that laboratory methods be \u201cfit for purpose\u201d and ensure detection of very low levels of STEC (or virulence markers) that may have survived antimicrobial treatments. FSIS recommends that methods be approved or used by a recognized government or independent body (e.g., FSIS, FDA, AOAC, AFNOR, ISO). 3. In some circumstances, multiple samples may be \u201cpooled\u201d after enrichment to save costs for testing. Because negative broths can dilute positive broths in the pooled test broth, \u201cwet-pooling\u201d analytical methods should ensure that sensitivity is not compromised. Wet-pooling refers to combining multiple samples for a single screening test after the samples have been enriched, i.e., incubated overnight in a broth as the first stage for detecting a pathogen. 4. It is important for testing laboratories to follow the testing protocol as written to ensure the method will perform as expected. This includes prewarming the enrichment broth to the incubation temperature before incubation to help ensure the greatest sensitivity, particularly for methods using enrichment periods less than 15 hours. KEY QUESTION Question: Why is it important to analyze the entire sample? Answer: Not analyzing the entire sample could lead to a significant increase in false negative results (negative results when the product is actually positive), which increase the likelihood that adulterated product enters commerce." "30 5. In circumstances when a test result for pooled samples is positive, it may be appropriate to re-test the individual sample-specific enrichments in an attempt to identify contaminated product more accurately. In such a procedure, it is important that the storage of the enrichments does not cause a decrease in the sensitivity of the individual test as compared to the pooled test. SUMMARY: KEY ELEMENTS OF A SAMPLE PLAN A sampling plan used to verify process controls should address the following: 1. Products to be tested 2. Lot size (usually in pounds and number of combo bins) 3. Statistical sampling method for selecting lots; percentage of lots that are sampled (lot sample) 4. Slice size (dimensions) and number of slices that comprise a sample 5. Collection method for selecting samples and slices from a selected lot 6. Procedures for preparing a sample for analysis (See Chapter VIII) 7. (Sub) sample size analyzed in a laboratory 8. Laboratory testing methods used (including sample size analyzed, enrichment procedures and size of portions analyzed) 9.

Actions to take when samples are positive (See Chapter V) KEY POINT It is unacceptable to change the lot definition based on the results of testing.","31 A critical limiting factor in a sampling plan is the maximum sample size that the laboratory can analyze. Given this maximum sample size, the sample is characterized by the number of slices and the slice size. Because the contamination occurs on the surface of the meat, slices should be as thin as possible and focus on surface tissue. Because it is expected that STEC organisms (or virulence markers) when present would be distributed unevenly in clumps, in constructing samples it is advisable to use many small sample slices rather than few larger slices (all slices should be of the same thickness). Using many small slices provides a more \u201crepresentative\u201d sample of the lot and greater likelihood of finding contamination. However, the limiting factor here is the time to collect many slices. At present, an N60 sample involves collecting 60 slices of a specified dimension. An N120 sample with slices \u00bd the surface area of those used for N60 would be expected to provide a greater likelihood of finding positive results, given everything else being equal. However, the time needed to collect an N120 sample might be twice as long as needed to collect an N60 sample. With limited resources, a likely consequence of the longer time needed to collect an N120 sample would be that fewer lots or combo bins would be sampled, thus losing the advantage of N120 sampling over N60 sampling. Over the years, the N60 sample has become the standard sample for beef trim products. It is important to remember that changing the slice size of samples or the number of slices for a sample could have an impact on the expected percentage of positive findings. Several factors can guide establishments in designing their sampling plans. Two of them are discussed here: percentage of positive samples in the product and degree of confidence desired for a given sample to test positive.

A. Percentage of positive samples of STEC (or virulence markers ) in the product \u2022 The percentage of positive samples is determined as the number of positive samples for the pathogen divided by the total number of samples tested, multiplied by 100. The process percent positive is the expected percentage of positive samples over time.

B. Degree of confidence desired for a given sample to test positive \u2022 The distribution of cells of STEC (or virulence markers) will depend on the levels on the carcasses and effectiveness of the control measures used by the establishment during slaughter, dressing, and fabrication (e.g., intervention treatments, temperature, and sanitation). An establishment that has verified that its control measures (e.g., organic acid spray wash or control of incoming materials) are effective in reducing contamination by the pathogen should have lower levels of STEC (or virulence markers).

VII.Factors Affecting the Design of Sampling","32 \u2022 The percentage of contaminated slices within a contaminated lot might likely be small. Thus, large numbers of slices for a sample are needed to determine with high confidence that a sampled lot has STEC (or virulence markers) cells. Table 5 shows the number of slices that would need to be collected to have 95% confidence of detecting STEC (or virulence markers) in the sample consisting of a random collection of n slices, assuming a specified true percentage of contaminated slices within the lot.

Table 5: Calculations used to derive the number of slices given in the table assume that the \u2018sizes\u2019 of the slices are the same (based on slice size used for N60 samples). Percentage positive slices 0.5% 1% 1.7% 2.5% 5% 7.5% 10% 15% 23% Number of slices needed 598 299 178 119 59 39 29 19 12 Table 5 shows that about 60 selected slices are needed to have a 95% confidence that contamination will be detected when the percentage of potential slices within a single lot (available for selection) that are contaminated is equal to 5%.

Selecting 12 slices only provides the same degree of confidence of finding a positive when the true percentage of contamination is about 23% within the lot. The above table suggests that if sensitivity greater than that of N60 sampling is desired, more slices (i.e., more surface area) would be needed. Since each slice varies in thickness, and thus in weight, the entire N60 sample is portioned into a 325g or 375g analytical portion size, which is a requirement of the FSIS method and the portion size industry typically uses, respectively. It is possible to obtain more sensitivity by taking larger (number of slices) samples. For example, two N60 samples per lot could be collected, for a total of 120 slices (of the same size). From Table 5, this would provide about 95% confidence of detecting contamination if 2.5% of the slices within the lot were contaminated. The costs with such sampling, however, could be double that of N60 sampling, assuming that all lots were to be tested, because the time to collect the samples could be doubled, and two samples rather than one sample would be analyzed. To help mitigate the latter cost, the wet-pooled procedure for testing could be used." "33 A collection method known as N60 (mentioned above) is often used for monitoring incidence of STEC (or virulence markers) in beef trim products manufactured by the industry. The \u201860\u2019 refers to the number of slices that are used in constructing the composite sample. The slices are collected randomly from the lot in order to help ensure a good \u2018representative\u2019 sample from the product within the lot. The collection method may be as follows:

Lot size: 5 combo bins consisting of 2,000 pounds each, for a total of 10,000 pounds trim

Number of slices: 60 slices of product sliced from the surface of the meat, 12 slices from each combo bin

Slice size: Each slice is about 6.25 grams and 1\8 inch thickness

Sample size: 375 grams, composed from the 60 slices

1. Take 12 slices of product, randomly selected from and throughout each combo bin, such that each consists of product of about 6.25 grams with thickness of no more than 1\8 inch, to help ensure that the sample will consist of as many slices from the carcass surface (where the STEC organisms or virulence markers are more likely to reside) as feasible to achieve the desired sample weight (325 or 375 g). As a guide, the dimensions of the sample can be about 3 inches in length and 1 inch in width.
2. If for some reason, there are less than 5 combo bins from which product is to be collected, a total of 60 surface slices from the available combo bins would still be taken. For example, if there are 2 combo bins to be used for grinding, 30 surface slices from each combo bin to make a total of 60 surface slices would be taken; if there were 3 combo bins, 20 slices, and so forth, would be taken.
3. Combine (composite) slices for every lot \u2013 the combined 60 slices is referred to as a composite sample.

VIII. Further Discussion

KEY QUESTION Question: Why is it important to take samples originating from the exterior carcass tissue? Answer: Contamination introduced during the slaughter process occurs on the surfaces of the carcass. So collecting samples from the original surfaces of the carcass increases the likelihood of detecting contamination if it is present.

KEY QUESTION Question: Why is it important that sample slices be thin? Answer: Sample slices should be thin. This maximizes the number of slices that can be collected to achieve the desired sample weight (325 or 375g)." "34

4. Store the sample at temperatures between 7 and 10 \u00baC (44 - 50 \u00b0F), and send to the laboratory. The sample should be analyzed within 24 hours of collection.
5. At the laboratory the sample must be mixed before selecting the material to be analyzed. It is important that an approximately equal amount of material from every slice be included in the material that is being analyzed.
6. At the laboratory, if necessary, create sub-samples to be analyzed separately (typically five 75-gram sub-samples), though some

procedures allow for the whole 375 gram sample to be analyzed. 7. Incubate (enrich) each sub-sample to ensure adequate growth of any STEC cells. 8. Analyze each sub-sample for the presence of STEC \u2013 confirm as positive or negative all presumptive positive results for STEC or assume presumptive results are positive. 9. Investigate possible sources of the contamination, the process, and the controls that have been designed to prevent contamination if a result is positive. 10. Dispose of the positive lot and all other implicated product or send for full lethality. The method of analysis should be equivalent to that of the current method that the FSIS laboratories use as cited in the Microbiological Laboratory Guidebook (MLG)

(<http://www.fsis.usda.gov/wps/portal/fsis/topics/science/laboratories-and-procedures/guidebooks-and-methods/microbiology-laboratory-guidebook> ). Some Variations of N60: The N60 collection method being used by most establishments involves 5 combo bins defining a lot. This method was designed to detect contamination slicespecific incidence at a within-lot contamination of 5%; lower percentages, averaged over the lot, would not be detected so readily. The results from Table 5 indicate a possible reason for this, namely the number of slices per combo bin (12 for N60) is too small to detect contaminated combo bins. Consequently, FSIS recommends establishments decrease the production lot size from 5 combo bins to 1 combo bin in order to provide greater assurance that contamination is detected within combo bins. That is, for the N60 method, as described above, for each combo bin there would be 60 surface slices collected. If the combo bin-specific test is positive, the product in the combo bin is sent for cooking; if negative, the product from the combo bin is sent for grinding, provided", "35 that there is no evidence that the process is out of control, based on the percent of positive results for neighboring lots that had been tested, or for any other reason known that could permit contamination not to be removed as effectively as normal. Wet-Pooling of Samples Using one combo bin as a lot may increase the cost of analysis. One way to help reduce the laboratory costs of analyses when testing each combo bin would be to enrich each N60 sample, and then pool aliquots of the individual enrichments from the five sampled combo bins. This means that the pooled aliquot represents five N60 samples. This lab method should ensure that a single positive sample pooled with multiple negative samples does not compromise the sensitivity of the testing method (the sensitivity of the test compared to the test used by FSIS). Diagram 1: The variation of N60 sampling shown (below) is an example of a wet pooled sample. In this situation, if the laboratory pooled sample is positive, then the laboratory would separately analyze the 5 enriched samples (each representing an N60 sample from each of the combo bins) to ascertain which of the combo bins represented in the laboratory pooled sample likely contributed to the positive pooled aliquot sample result. If the enrichment step is done properly, at least one of the 5 enriched samples would be found positive. The establishment would divert the one combo bin represented by the positive sample to further processing, such as cooking, to destroy the pathogen. In such a procedure, it is important that the storage of the enrichment samples does not cause a decrease in the sensitivity of the individual sample test as compared to the test on the pooled sample. If none of the individually analyzed N60 enriched samples was found positive, then this might indicate a problem with the enrichment procedure or with the sample handling. In such a case, all product within the 5 combo bins, even though they individually tested negative, would need to be cooked or disposed of because the testing did not identify the positive bin.", "36 Diagram 2:

Variation of N75 Sampling (below) depicts another variation of an STEC testing program with wet pooling. In this example, a lot is defined to be 5 combo bins, with 15 portions from each of 5 combo bins enriched. Aliquots of the enrichment from 5 combo bins are pooled and tested for an initial screening test for STEC. If the screening test for the pooled composite sample is positive, then each of the individual N15 aliquots are tested with screening tests to determine which combo may be the source of contamination. However, in this situation, further screening to determine which of the combo bins may be the source of contamination is not possible because the N15 enrichment broths do

Diagram 1: Variation of N60 Sampling N60 sample from Combo A N60 sample from Combo B N60 sample from Combo C N60 sample from Combo D N60 sample from Combo E Alliquots from Combos A-E pooled What are the results from the screening test of the composite sample? Presumptive Positive What are the results from confirmatory testing of individual alliquots? Confirmed Positive Combo A Confirmed Negative Combo B Confirmed Negative Combo C Confirmed Negative Combo D Confirmed Negative Combo E What actions should be taken in response to the confirmatory test results? Corrective Actions including appropriate product disposition (lethality treatment or landfill) and records

Combo A Released to Commerce Combos B-E Negative What is the product disposition? Released to Commerce Combos A-E", "37 not provide enough statistical confidence to rule out any one of the combo bins as the source of contamination. Therefore, the establishment should treat all 5 combo bins as positive.

FSIS assumes that, at any time, there are identifiable processing factors that have an effect on the expected percentage of found positive results. Thus, the expected percentages of found positive results can vary as these identifiable factors vary over time. By defining criteria for high event periods (HEP), FSIS is trying to identify periods of processing such that if the process as constituted during that period were to continue, the expected percentage of found contaminated samples would be greater than the expected percentage that normally is obtained. There are also factors that influence the results that cannot be identified or specifically control for and, thus, make it impossible to know how many positive results would be found among a fixed number of samples. The impact of these factors FSIS summarizes in a mathematical model by assuming that there is a random component (set of factors) of the process that affects results in a way that FSIS can only describe through a specified probability distribution, as explained in more detail below. Accordingly, for describing results associated with a processing period, the model identifies two parameter objects: 1) the expected \u201clong term\u201d percentage of found positive results (that would be found over an infinitely large number of tested samples); and 2) a probability distribution that describes the distribution of the number of positive results among a small number of tested samples. The

model's objective is to identify periods of processing (considering these to be High Event Periods) where the first parameter - the expected percentage of found positive results - is greater than some specified value. What makes this difficult is that the evidence is based on small numbers of tested samples and, thus, the results obtained from these samples might not reflect the true expected percentage of positive results associated with the process because of the randomness of the obtained results caused by factors that are not identifiable or uncontrollable. FSIS does not want to recommend declaration of a HEP unless it can be highly confident that there are identifiable factors that contribute to the high percentage of found positive results. The degree of confidence obtained for a correct inference that the process was out of control as defined here for HEP depends on the number of samples tested and the observed percentage of positive results. To compute the degree of confidence associated with results from a small number of samples, FSIS specified the probability distribution that describes random results. FSIS followed conventional procedures for doing this by assuming the number of positive results,  $m_t$ , for  $n_t$  samples in a period indexed by  $t$ , is distributed as a binomial distribution,  $b(m_t, n_t, p_t)$ , where  $p_t$  is the assumed expected percentage of found positive samples (or the probability that a specific sample will be found positive), and  $n_t$  is the number of samples being tested. If, from the results, FSIS statistically infers that  $p_t$  is greater than 5%, with a high degree of confidence,"<sup>39</sup> FSIS says that an HEP has occurred. Because of randomness, it is possible that a process during a period that has an expected percentage of positive results - the value of  $p_t$  less than 5% could have, for the few samples collected in that period, an observed percentage of positive results greater than 5%. If, however, the observed percentage of positive samples is sufficiently large, FSIS can statistically infer with high confidence that the  $p_t$  is greater than 5%. Consequently, imposing statistical criteria to provide a high degree of confidence that the (true) process percentage of positive results exceeds 5% means that the observed percentages of positive results that lead to HEPs are greater than the 5% target. The smaller the number of samples, the greater the observed percentage of positive results needed to infer that the true or expected percentage of positive results produced by the process was greater than 5%. The greater the degree of confidence desired, the greater the observed percentage of positive sample needed, for the same number of samples. Because industry is continuously testing product, FSIS set a relatively high degree of confidence of nearly 99% confidence before declaring a local HEP or a systematic HEP for a day when more than 60 samples were tested. This means that, if the expected percentage of positive results were actually 5%, there is only about a 1% probability that an HEP would be (incorrectly) declared for the period being considered. FSIS believes that when HEPs are identified, there would likely be factors that could be identifiable and controllable as causing the high percentage of positive samples. Calculations: FSIS assumed that the number of found positive results,  $k$ , in  $n_t$  samples is distributed as a binomial distribution as described above. This means the probability of  $k$  found positive results in  $n_t$  samples assumed an expected percentage of found positive samples,  $p_t$ , is given by the formula.  $P(k|n_t, p_t) = \frac{n_t!}{k!(n_t-k)!} p_t^k (1-p_t)^{n_t-k}$  (1) The degree of confidence,  $C$ , that  $m_t$  found positive samples in  $n_t$  tested samples suggests that  $p_t$  is greater than 5% is calculated as:  $C(m_t, n_t) = \sum_{k=0}^{m_t} P(k|n_t, 0.05)$  (2) where  $k$  is an index for the summation of the probabilities of  $k$  found positive results. For example, FSIS specified that in 10 samples, if 3 (or more) are found positive, there would be at least nearly 99% confidence that the expected process-specific

percentage is greater than 5%. The more exact confidence is 0.988496. If only 2 positive results were to occur, the confidence would be 0.914 which is considerably less than FSIS's approximate target of nearly 0.99. Accordingly, FSIS set its criterion for 10 samples to be 3 or more positive", "40 findings. Table 1, presented in the main document, provides the degree of confidence obtained for the set of criteria associated with the local HEP (3 or more positive results out of 10 samples) and the systemic HEP when more than 60 samples in a day are tested. Also included is the observed percentage of positive samples. In summary, FSIS built in a statistical tolerance, requiring nearly 99% confidence before considering that the process, with an observed percentage of positive test results greater than 5%, has a true expected percentage of positive results greater than 5%. In such circumstances, the establishment should take special actions. FSIS also identified a more severe type of HEP (short-term systematic), for which FSIS stated that nearly 99.95% confidence is needed to assert that the true expected percentage of positive results exceeds 5%. In such instances, the establishment should take maximum action. The criterion is 7 or more positive results in 30 samples. The confidence, based on Eq. 2, that the true expected percentage of positive results is greater than 5% when 7 positive results are found in 30 samples is 99.943%, which is near 99.95%. FSIS using tolerances (i.e., requiring a high degree of confidence) increases the likelihood that time and resources the establishment spends in response to HEP will be fruitful in finding problems that will lead to improvement. Improvement over time would lead to a lower percentage of positive results. FSIS will be monitoring the percentage positive (through its sampling programs), and expects that in the coming years, the target percentage that FSIS will use will decrease from the present 5%."]}, {"file\_name": "FSIS\_GD\_2014\_0010", "title": "FSIS Compliance Guideline for Meat and Poultry Jerky Produced by Small and Very Small Establishments", "num": "FSIS-GD-2014-0010", "id": "1b0580ef82585d35ffbb20afb5e27b6fd2942f91f5e2b50d0df7b59626be991f", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/import/Compliance-Guideline-Jerky-2014.pdf", "type": "pdf", "n\_pages": 54, "word\_count": 20124, "text\_by\_page": ["1 This guidance document is designed to help very small meat and poultry establishments that manufacture jerky identify: \u2022 The key steps in the jerky process needed to ensure safety; and \u2022 The scientific support available to help develop a safe process and product. FSIS USDA FSIS Compliance Guideline for Meat and Poultry Jerky Produced by Small and Very Small Establishments 2014 Compliance Guideline", "2 This Compliance Guideline provides guidance to assist establishments in meeting FSIS regulations related to jerky processing. The guideline also contains recommendations to help industry produce a safe product based on the scientific information available in the literature. Guidance represents best practice recommendations by FSIS, based on the best scientific and practical considerations, and does not represent requirements that must be met. Establishments may choose to adopt different procedures than those outlined in the guideline, but they would need to support why those procedures are effective. It is important to note that this guideline represents FSIS's current thinking on this topic and should be considered usable as of the issuance date. This version of the guidance document, dated August 2014, replaces previous versions of the document which was last updated in July 2012. FSIS updated the guideline based on four comments from three trade associations and one individual. The following are changes made in response to comments: \u2022 Broken link on page 4 (see footnote) has been changed to a link to a report from the"]}]

New Mexico Department of Health; \u2022 Surface preparation step was added to the step-by-step guide on page 7; \u2022 Definition of shelf-stability and recommended shelf-stability parameters were clarified on page 15; \u2022 Continuously introducing steam option was clarified on page 22; \u2022 Attachment 4, which provides guidance on supporting the continuously introducing steam option, was added. A more detailed summary of the comments and FSIS\u2019 responses can be found in Attachment 1. In addition to making changes in response to public comments, FSIS also made the following changes in response to questions submitted through askFSIS: \u2022 Clarified on page 8 that the lethality treatment of poultry jerky should achieve at least a 5.0-log<sub>10</sub> reduction of *Salmonella* spp.; \u2022 Provided guidance on pages 13 \u2013 14 on how to calibrate a humidity recorder; \u2022 Clarified on page 19 that reference to the cooking time in the humidity options in Appendix A refers to the entire cooking time (including come up time), not just the time during which the temperature in Appendix A is achieved and maintained (e.g., 145\u00b0F for 4 minutes); \u2022 Clarified in the text on page 19 that if an establishment using Appendix A as support for the lethality treatment introduces steam or seals the oven, cooking time should never be less than one hour; and \u2022 Clarified the documentation that should be collected to support that humidity is being implemented consistent with Appendix A when the sealed oven or continuously introducing steam methods are used on pages 21 and 22. Although comments will no longer be accepted through regulations.gov on this guidance document, FSIS will update this document as necessary should new information become available.", "3 Compliance Guideline for Meat and Poultry Jerky Produced by Small and Very Small Establishments Table of Contents Purpose 4 Background 4 Step-by-Step Guide for Jerky Processing 5 Critical Operational Parameters during the Lethality Treatment 9 Scientific Support Available for Jerky Processing 18 References 29 Helpful Websites 31 Attachment 1: FSIS Response to Comments 32 Attachment 2: Time, temperature, and humidity combinations reported in the literature for beef jerky that achieve at least a 5\u2013log<sub>10</sub> reduction in *Salmonella* and *E. coli* O157:H7 40 Attachment 3: Making Your Own Wet bulb (Reprinted with Permission from the University of Wisconsin) 49 Attachment 4: Example Time-Temperature Recorder Chart to Support Option to Continuously Inject Steam 53", "4 Compliance Guideline for Meat and Poultry Jerky Produced by Small and Very Small Establishments Purpose This guideline is designed to help small and very small meat and poultry establishments that manufacture jerky to identify: \u2022 The key steps in the jerky process needed to ensure safety; and \u2022 The scientific support available to help develop a safe process and product. This guideline is not intended to set any regulatory requirements. This document replaces previous versions of the guideline last updated in July 2012. Background Meat or poultry jerky is a ready-to-eat (RTE), dried product that is considered shelfstable (i.e., it does not require refrigeration after proper processing). Following a 2003 salmonellosis outbreak from *Salmonella* Kiambu in jerky produced in New Mexico, FSIS published the first version of the Compliance Guideline for Meat and Poultry Jerky Produced by Small and Very Small Establishments. The Compliance Guideline provided guidance for small and very small meat and poultry establishments on the critical steps for jerky processing and the controls needed at each of these steps to ensure a safe product is produced. One potential cause of the 2003 *Salmonella* Kiambu outbreak in jerky was the very slow drying process under low humidity conditions (1% Relative Humidity - 82\u00b0C dry bulb, 30\u00b0C wet bulb), which allowed *Salmonella* organisms to dehydrate during drying and become resistant to heat.

Therefore, the first version of the jerky compliance guidelines emphasized the need for high levels of humidity during jerky processing. Since 2003, a number of journal articles have been published that has increased scientific understanding of the critical factors during jerky processing including the role of humidity. This document updates and replaces the 2007 and 2012 versions of the guideline to reflect the most up-to-date science and understanding of jerky processing. This guideline also addresses concerns identified through Food Safety Assessments (FSAs) and askFSIS questions and responds to public comments received on the 2012 version. 1 <http://aces.nmsu.edu/ces/nmhs/documents/albanese.pdf> One potential cause of the 2003 Salmonella Kiambu in jerky outbreak was the very slow drying process under low humidity conditions", "5 Step-by-Step Guide for Jerky Processing Below is a summary of the eight (8) general processing steps used in jerky production. Although an establishment's process may not include these same steps, the lethality treatment followed by drying should be used to produce a safe product. Other steps such as the intervention and post-drying steps may be used by establishments when the lethality and drying steps do not achieve adequate lethality. Further descriptions of the key steps in the jerky process, including the microbial interventions that can be applied to ensure safety, are included in the pages that follow. \uf0d8Step 1 - Strip preparation: Whole muscle is sliced or ground; ground product is formed into strips (some jerky is formed). \uf0d8Step 2 \u2013 Marination: The strips are marinated in a solution that often contains salt, sugar, and flavoring ingredients. \uf0d8Step 3 \u2013 Interventions: Antimicrobial interventions before, during, and after marinating the strips of raw product may be added to increase the level of pathogen reduction beyond that achieved by heating alone. \uf0d8Step 4 - Surface preparation: Strips are heated using a low temperature heat step, which makes the surface tacky to aid in smoke adherence and improve product texture. \uf0d8Step 5 \u2013 Lethality: The lethality treatment is defined as the process step or steps used to destroy pathogenic microorganisms on or in a product to make the product safe for human consumption. The lethality treatment is considered to include the time when the product is placed in the heated oven (including surface preparation and color setting) until the product reaches the desired lethality time/temperature combination (also referred to as \u201cthe cooking time\u201d). In order to achieve adequate lethality, it is important that an establishment's actual process adheres to the following critical operational parameters (see Key Definitions on page 8) in the scientific support: \u2022 Product time-temperature combination \u2022 Relative humidity \uf0d8Step 6 \u2013 Drying: Drying is the process during which water (moisture) is removed from the product. After the lethality treatment, jerky is dried to meet a water activity level sufficient to prevent the growth of microorganisms, especially toxigenic microorganisms, such as *Staphylococcus aureus*. \uf0d8Step 7 \u2013 Post-drying heat step: A post-drying heat step may be added to increase the level of pathogen reduction beyond that achieved by heating alone. \uf0d8Step 8 \u2013 Handling: Product is often handled after the lethality and drying steps and prior to packaging.", "6 Jerky producers (and all producers of RTE product) are required to control the food safety hazards in their products (9 CFR 417.4(a)) and to document that their Hazard Analysis and Critical Control Point (HACCP) systems work according to 9 CFR 417.5(a). Establishments producing RTE products need to achieve lethality of pathogens (e.g., *Salmonella*) in the product, and stabilize the product to inhibit the growth of spore-forming bacteria (e.g., *C. botulinum* and *C. perfringens*). In addition, jerky producers need to ensure the growth of toxigenic microorganisms, such as

*Staphylococcus aureus*, is controlled during the process and prevented during the distribution and storage of the finished product. This guideline provides steps jerky processors can take to ensure that the jerky processes they employ effectively control these hazards. The guideline discusses each step in the jerky process in more detail below with key considerations related to pathogen reduction or control highlighted for each step. Each process is unique, so some processors may not use all 8 steps. Some may perform the steps below in different order, or some may use additional steps.

\uf0d8Step 1 - Strip preparation: Whole muscle is sliced or ground; ground product is formed into strips (some jerky is formed). It is critical for establishments to use source materials prepared under good manufacturing practices (GMPs) designed to minimize contamination and the presence and growth of pathogens of public health concern, so the initial pathogen load is not higher than what the process is designed to reduce. Establishments that choose to purchase source materials known to be contaminated with pathogens of public health concern, such as *Salmonella* or shiga toxin-producing *Escherichia coli* (E. coli) (STEC) organisms such as E. coli O157:H7 or E. coli O45, should pay special attention to the controls they put in place to ensure cross-contamination between raw and RTE product does not occur.

\uf0d8Step 2 \u2013 Marination: The strips are marinated in a solution that often contains salt, sugar, and flavoring ingredients. Establishments should use non-meat ingredients for marinades and spice mixes that are prepared under GMPs designed to minimize contamination and the presence and growth of pathogens of public health concern, so the initial pathogen load is not higher than what the process is designed to reduce. FSIS recommends that establishments use a new liquid marinade solution or dry spice mix with each production batch to reduce chances of cross-contamination from one batch of production to another. If an establishment does reuse a marinade or spice mix, it should consider and address the potential hazards associated with cross-contamination from one batch of production to another.

\uf0d8Step 3 - Interventions: Antimicrobial interventions before, during, and, after marinating the strips of raw product have been shown to increase the level of pathogen reduction beyond that achieved by heating alone. Some heating processes may not deliver an adequate lethality and, thus, may require an additional intervention step to ensure product safety. Examples of interventions that may increase the lethality of the process are:<sup>7</sup>

Preheating the meat or poultry jerky strips in the marinade to a minimum internal temperature of 160\u00b0F will provide an immediate reduction of *Salmonella* (Harrison and Harrison, 1996). Heating in marinade may produce unacceptable flavors for some products; however, other liquids such as water could be used. The times and temperatures in FSIS Appendix A: Compliance Guidelines For Meeting Lethality Performance Standards For Certain Meat and Poultry Products (referred to throughout this document as Appendix A) could be used for preheating in the liquid, although the product internal temperature should be monitored to ensure adequate lethality is achieved.

\u2013 Dipping the product in 5% acetic acid for 10 minutes before placing it in the marinade can augment the log reduction effects of drying but not enough to eliminate pathogens (Calicioglu, 2002 & 2003). This intervention may also result in an undesirable flavor.

\u2013 Dipping the product in 1:2 or 1:3 mixtures of calcium sulfate (Milonix Safe 2O\u2122) and water for 30 seconds or dipping in acidified sodium chlorite (Keeper\u00ae) at concentrations between 500 and 1,200 ppm can reduce the level of *Salmonella*, *Listeria monocytogenes* (Lm), and E. coli O157:H7 compared with no pretreatment. These pretreatments were effective in both dehydrators and smokehouse processing (Harrison

et al., 2006). \uf0d8Step 4 - Surface preparation: Strips are heated using a low temperature heat step which makes the surface tacky to aid in smoke adherence and improve product texture. Humidity is often not introduced until the next step, the lethality treatment. The lack of humidity during the initial surface preparation step is generally not a food safety concern because the step is usually too short (30 minutes or less) to dry out the product to such a degree that the heat resistance of *Salmonella* would be increased. This step may include or be followed by a color setting step during which humidity is also not introduced. This color setting step plus the surface preparation step should be 30 minutes or less in total. If an establishment uses a preparation or color setting step that is longer than 30 minutes, it should provide support for why the lack of humidity does not result in the product drying out before the lethality treatment. \uf0d8Step 5 - Lethality treatment: The lethality treatment is defined as the process step or steps used to destroy pathogenic microorganisms on or in a product to make the product safe for human consumption. The lethality treatment is considered to include the time when the product is placed in the heated oven (including surface preparation and color setting) until the point at which the product reaches the desired lethality time-temperature combination (also referred to as the \u201ccooking time\u201d). In order to achieve adequate lethality, the establishment\u2019s actual process needs to adhere to the following critical operational parameters (see Key Definitions on page 8) in the scientific support:"8 \u2022 Product time-temperature combination \u2022 Relative humidity In recent years, several jerky products have been found to be adulterated with *Salmonella* or *E. coli* O157:H7. Often the contamination has been linked to inadequate lethality treatment. The lethality treatment of meat jerky should achieve at least a 5.0-log<sub>10</sub> reduction of *Salmonella* spp. and at least a 5.0-log<sub>10</sub> reduction for shiga toxin-producing *Escherichia coli* (*E. coli*) (STEC) for products containing beef as recommended in the *Salmonella* Compliance Guidelines for Small and Very Small Meat and Poultry Establishments that Produce Ready-to-Eat (RTE) Products. The lethality treatment of poultry jerky should achieve at least a 5.0-log<sub>10</sub> reduction of *Salmonella* spp. Although poultry jerky is considered to fall under the performance standard in 9 CFR 381.150 (i.e., a 7.0-log<sub>10</sub> reduction of *Salmonella* spp.), the regulation allows for the use of an alternative lethality that achieves an equivalent probability that no viable *Salmonella* organisms remain in the finished product. Research has supported that a 5.0log<sub>10</sub> reduction in *Salmonella* is sufficient for such shelfstable products. Indeed, the FSIS Risk Assessment of the Impact of Lethality Standards on Salmonellosis from Ready-to-Eat Meat and Poultry Products found that there would not be a significant increase in the cases of salmonellosis if jerky and other shelf-stable products achieved a 5.0-log<sub>10</sub> vs. 7.0-log<sub>10</sub> lethality. In addition to *Salmonella* spp., the lethality treatment of meat and poultry jerky should achieve at least a 3.0-log<sub>10</sub> reduction in *Lm*, although a 5.0-log<sub>10</sub> reduction or greater is desirable for providing an even greater safety margin for ensuring that *Lm* does not grow to detectable levels during storage. However, establishments are not required to validate that their process achieves reduction in *Lm* (or STEC for products containing beef) if it achieves sufficient reductions in *Salmonella* because *Salmonella* is more heat resistant than other pathogens and is, therefore, considered an indicator of lethality. Establishments should make sound decisions in the hazard analysis that support that source materials were prepared using GMPs and other process controls as discussed in the previous steps of strip preparation and marination such that a 5.0-log<sub>10</sub> reduction in *Salmonella* results in the production of a safe product. Official establishments

choosing to use cooking to achieve lethality before drying may consider a number of different KEY DEFINITIONS The lethality treatment is defined as the process step or steps used to destroy pathogenic microorganisms on or in a product to make the product safe for human consumption. The lethality treatment is considered to include the time when the thermal processing begins (e.g., the product is placed in the heated oven) until the point at which the product reaches the desired lethality time-temperature combination (also referred to as the \u201ccooking time\u201d). Critical operational parameters are those parameters of an intervention that must be met in order for the intervention to operate effectively and as intended. Such parameters include but are not limited to time, temperature, water activity, concentration, relative humidity, and type of equipment (to the extent that the use of different equipment would result in an inability to achieve the critical parameters of the study).", "9 types of scientific documents to support the time-temperature-humidity combination used in the actual process. Such types of scientific support documents include: \u2022 Compliance Guidelines (e.g., Appendix A) \u2022 Journal articles \u2022 Challenge studies \u2022 In-plant data Finished product testing would not be considered adequate scientific support for the process used on its own, however, because such testing does not support that at least an adequate reduction of *Salmonella* spp. is achieved by the process. An in-depth discussion of considerations for each of these types of scientific support documents, along with examples, is discussed in the section titled: Scientific Support Documents for Jerky Processing. Critical Operational Parameters during the Lethality Treatment Regardless of the scientific support document used, it is important that an establishment's actual process and procedures relate and adhere to the critical operational parameters in the scientific support in order to achieve adequate lethality. There are several critical operational parameters that are important for jerky processing that will be reviewed. Product time-temperature combination One of the critical operational parameters during the jerky process is the time-temperature combination the product achieves. Most often the temperatures used during the lethality treatment that are reported in scientific support documents, such as the Appendix A guidelines, are the temperatures that the product should reach. FSIS has found that establishments will use these same temperatures to set critical limits for the oven temperature. However, setting the oven temperature to the temperature in the support is not appropriate because it does not ensure that the product will reach the same internal temperature, which is critical to ensure adequate lethality is achieved. For this reason, FSIS recommends that FSIS has found through FSAs that many establishments use temperatures from support documents to set critical limits for the oven temperature; however, setting the oven temperature to the temperature in the support does not ensure that the product will reach the same internal temperature which is critical to ensure adequate lethality is achieved. The FSAs show that some establishments do not measure or verify that the product has achieved the desired internal lethality temperature until after drying. FSIS does not recommended verifying product temperatures only after drying because the product may have dried out before the lethality temperature was reached, resulting in lower than expected pathogen reduction.", "10 establishments monitor the internal product temperature. Product internal temperature can be measured by inserting a thermocouple probe into the center of a beef strip. Proper insertion may be difficult because the product is so thin; therefore, FSIS recommends that establishments slice one piece of jerky twice as thick as normal so that the probe can be inserted. If this thicker piece reaches the lethality

temperature, the thinner pieces should as well. In addition, to accurately measure the product temperature, the establishment should understand factors that could affect the temperature of the product. These factors include cold spots in the oven, as well as variation in oven temperature during different seasons. Although monitoring product temperature is strongly encouraged, establishments can use the oven or smokehouse temperature in place of the product temperature, provided that the establishment has a consistent product and process and has sufficient data correlating the oven temperature selected with the product temperature in the scientific support. In addition to the product temperature, the amount of time the product is held at this temperature is also critical to ensuring that adequate lethality is achieved. It is important for the establishment to understand how the actual temperature of the product was taken, the time it takes the product to reach the target temperature (known as the come-up time or CUT), and the amount of time the product is held at the target temperature compared to the scientific support documentation. If the product is held at the target lethality treatment for less time than what was used in the scientific support, then adequate lethality may not be achieved.

**Relative Humidity**

In addition to the product time-temperature combination, the relative humidity (e.g., steam) in the oven is also critical to achieve adequate lethality in jerky. It is important that the establishment maintains humidity according to its scientific support. If relative humidity is not added or maintained by the process, the establishment should maintain scientific support demonstrating that humidity is not a critical operational parameter. Some jerky processors may be concerned that adding humidity will affect the ability to dry the meat or poultry and result in unacceptable product texture; however, the lethality treatment during which relative humidity is applied takes very little time. Adding humidity during the lethality treatment should accelerate subsequent drying and prevent case-hardening, which may actually improve product texture.

**KEY DEFINITIONS**

Relative Humidity is defined as the degree of saturation of the air by water (vapor), expressed as a percentage. Relative humidity describes the relation of the existing vapor pressure at a given temperature to the maximum vapor pressure at that temperature. Air at a given temperature can absorb vapor until its saturation (100%). The difference between the dry and wet bulb temperature is the relative humidity at that temperature. The following website <http://www.ringbell.co.uk/info/humid.htm> contains a function for calculating the relative humidity given the wet and dry bulb temperatures.", "11 Without sufficient humidity the product surface may dry too quickly, and the bacteria may become more heat resistant. Relative humidity around a product during the lethality treatment promotes lethality in two ways:

- \u2022 First, the humidity reduces surface evaporation and the energy or heat that evaporation removes from the product during heating. If sufficient relative humidity surrounding the product is not maintained during the lethality treatment, undesirable evaporative cooling at the surface will occur, and the product will not reach the desired temperature. Producing products under conditions of high humidity early in the cooking process reduces evaporative cooling allowing products to reach higher product surface temperatures which results in a greater reduction in microorganisms.
- \u2022 Second, the humidity keeps the product surface (and any pathogens) more moist and prevents unwanted concentration of solutes (e.g., sugar and salt) as a result of drying. Research has demonstrated that bacteria can become more heat resistant as their moisture levels decrease, and increased concentrations of solutes, especially sugars, increase the heat resistance of bacteria. Therefore,

the drying of the product surface before the pathogens are destroyed will increase pathogen heat resistance and allow them to survive the heating process. By incorporating humidity to minimize evaporation, the D values (time at a constant temperature necessary to destroy 90% or 1-log10 of the target organism) that are the basis for Appendix A and other scientific support documents remain valid (Goepfert, 1970; Goodfellow and Brown, 1978; Faith, N.G. et al. 1998). For these reasons, it is crucial that the processor prevent drying of the product until a lethal time-temperature combination is attained. In order to be most effective, the humidity should be applied during the lethality treatment and before the drying step occurs. Although the lethality treatment includes the time when the product is placed in the heated oven until the product reaches the desired lethality time and temperature combination (the \u201ccooking time\u201d), establishments may not introduce relative humidity into the process until 15 to 30 minutes after the product is placed in the heated oven. The establishment would do so because of the previous step of surface preparation that is needed to set the surface to aid in the adherence of smoke. As discussed earlier, the lack of humidity during this initial step is not a food safety concern because of its short duration. In addition to applying humidity early in the lethality treatment, FSIS also recommends that establishments treat the lethality and drying steps as separate stages to ensure that lethality is achieved before the product dries out. Therefore, the establishment should measure and verify the desired product temperature has been met before the drying stage. One way for an establishment to know that the product has not dried out before a lethal time-temperature combination is attained is to measure the water activity of the", "12 product after the lethality treatment but before drying and again after drying. Some published articles (for example, Buege et al., 2006a) report the water activity at these points in the process for comparison. Another approach is for the establishment to monitor the wet bulb temperature early in the process because it provides a good indication of product surface temperature, which strongly influences lethality (Buege, 2006a). Further explanation and directions for making a wet bulb thermometer are in Attachment 3. Although this information may be useful, establishments do not need such data to validate the process if they are able to demonstrate that their process can achieve the level of relative humidity in their scientific support. Some simple and practical measures that can be used to aid in meeting the humidity level utilized in the scientific support documents include:

- \u2022 Seal the oven: Close the smokehouse doors and oven dampers to provide a closed system and prevent moisture loss.
- \u2022 Add humidity:
  - o Place one or more shallow, wide pans of hot water in the oven to increase the humidity in the system. Conduct a test run to determine whether the water evaporates.
  - o Injecting steam or a fine water mist into the oven can also add humidity.

The use of a humidity sensor or the use of wet bulb and dry bulb thermometers (to measure relative humidity) would enable the operator to determine whether adequate humidity is being applied for either measure. In order to ensure that adequate humidity is attained, the establishment should monitor the humidity throughout the lethality treatment. The process should be monitored using wet and dry bulb thermometers (used to determine relative humidity) or a humidity sensor. The following website <http://home.fuse.net/clymer/water/wet.html> contains a function for calculating the relative humidity given the wet and dry bulb temperatures. A basic wet bulb thermometer can be prepared by fitting a wet, moisture-wicking cloth around a dry bulb thermometer. To maintain a wet cloth during the process, submerge an end of the cloth in a water supply. The

cloth must remain wet during the entire lethality treatment especially if smoke is applied. The establishment KEY DEFINITIONS The dry bulb temperature refers to the ambient air temperature. It is called \u201cdry bulb\u201d because the air temperature is indicated by a thermometer not affected by the moisture in the air or evaporative cooling that removes heat and moisture from the surface of the product. The dry bulb temperature is most commonly measured by jerky-makers. Jerky makers commonly measure the dry bulb temperature. The wet bulb temperature is the temperature indicated by a moistened thermometer bulb exposed to the air flow. A wet bulb thermometer measures the extent of cooling that happens as moisture dries from a surface, a process also known as evaporative cooling. The wet bulb temperature is always lower than the dry bulb temperature except when there is 100% relative humidity, when they will be identical. Because evaporative cooling occurs on the surface of thin jerky strips, the wet bulb temperature is a more accurate measure of product surface temperature. A sealed oven is generally defined as one in which the smokehouse doors and smokehouse oven dampers are closed to prevent moisture loss.", "13 should inspect the wet bulb sock prior to thermal processing, and the sock should be changed as necessary depending on its condition. Attachment 3 contains more details for creating a wet bulb thermometer. The use of a wet bulb thermometer is especially important for production at altitudes between 3,000 to 7,000 feet or areas of low humidity. Processing failures in the manufacture of jerky have occurred in establishments in New Mexico located between these altitudes (Eidson et al, 2000). Establishments located at higher altitudes will generally have a lower atmospheric pressure. This lower pressure leads to lower boiling points and faster evaporation from the product surface, which can lead to undesirable evaporative cooling and drying of the product surface. Furthermore, the relative humidity can be less at the higher altitude because of the lower air pressure (if the temperature at sea level and the high altitude is the same). As a result, at higher altitudes, the amount of moisture added to the smokehouse chamber necessary to achieve a given log reduction of bacteria may need to be increased to account for lower levels of humidity in the ambient (or room) air. Relative humidity in the ambient air will have an effect on the relative humidity in the smokehouse chamber, particularly when humidity is maintained by sealing the oven, because heat in the smokehouses is typically provided by heating ambient air that is passed over electrically-heated or steam-heated coils. For this reason, all establishments should also take into account variability in relative humidity in the ambient air throughout different times of year. Establishments will need to make adjustments to the amount of humidity added to the smokehouse chamber to account for changes in humidity in the ambient air at high altitudes or during dry months. These adjustments should be made on a case-by-case basis as part of the initial design of the system to ensure that the humidity in the actual process matches the level in the scientific support. FSIS recommends that establishments monitor relative humidity using wet and dry bulb thermometers or a humidity sensor with every lot or batch of product although FSIS does not require this monitoring frequency. Establishments have flexibility in how they address humidity in their HACCP systems. If relative humidity is addressed as part of a critical control point (CCP), the establishment is required to list the critical limits per 9 CFR 417.2(c)(3) and list and support the monitoring procedures and frequencies chosen for each CCP to ensure compliance with the critical limits per 9 CFR 417.2(c)(4) and 9 CFR 417.5(a)(2). Furthermore, per 9 CFR 417.4(a)(2), establishments are required to calibrate process-monitoring instruments as part of ongoing verification activities

and, per 417.5(a)(2), are required to support their verification procedures and frequencies of those procedures. If relative humidity is addressed in a prerequisite program, and the establishment determines that the implementation of that program results in potential hazards being not reasonably likely to occur, then it must have supporting documentation for the decisions made in the hazard analysis per 9 CFR 417.5(a)(1). NOTE: Accurate recordkeeping documenting the implementation of the critical operational parameters is critical to support the fact that safe products are produced. Inadequate or inaccurate recordkeeping (e.g., data entry error or unclear monitoring records) has contributed to jerky product recalls in the past, particularly when such records were associated with a lack of information regarding the implementation of all of the critical operational parameters for each batch or lot produced." "14 Often the owner's manual for humidity recorders recommends calibration on an annual basis. Establishments should follow the manual's instructions for calibration. Establishments may calibrate by comparing the temperature readouts from the microprocessor to the temperature and time plotted on the recorder charts to check for accuracy. For this procedure, FSIS recommends that the establishment calibrate the microprocessor controls before use and show that the calibration is accurate. This procedure can be performed in-house in a few simple steps: 1. The wet bulb and dry bulb probes can be placed in a bucket of hot water along with a National Institute of Standards and Technology (NIST) reference thermometer. Some establishments use a small propane burner to maintain the water at a constant temperature. 2. The NIST thermometer represents the known temperature standard, and the establishment can compare the wet and dry bulb probe readings on the microprocessor to the NIST device to verify accuracy of the probes. 3. Once the probe readings are verified on the microprocessor as being accurate, the temperature reading on the microprocessor can be compared to the chart recorder temperature. The chart recorder is then adjusted (if needed) to the microprocessor reading. These procedures for calibrating humidity recorders are provided as guidance to establishments; other procedures may be used, provided the establishment maintains support for the method chosen.

Step 6

Drying: Drying is the process during which water (moisture) is removed from the product. After the lethality treatment, jerky is dried to meet a water activity level sufficient to prevent the growth of microorganisms, especially toxicogenic microorganisms such as *Staphylococcus aureus*. Jerky is a shelf-stable product. After drying is complete, the establishment should monitor or verify the water activity to demonstrate that the product has attained shelfstability in accordance with the scientific support. FSIS does not have a standard of identity for jerky in its regulations. However, jerky has historically been dried to an MPR of 0.75:1 or below as described in the FSIS Food Standards and Labeling Policy Book. FSIS is aware that some manufacturers rely upon the MPR, rather than water activity, for determining whether their process adequately dries the jerky to produce a shelfstable product. MPR is an inappropriate indicator of shelf-stability. Water activity (also referred to as aw), measured by an instrument such as a water activity meter, is the more appropriate indicator to verify jerky is properly dried for food safety. This is because water activity is a better measure of available water (or water that is not bound by other components) for microbial growth than is MPR. Minimizing available water (e.g., achieving a sufficiently low water activity) is necessary to achieve shelf stability, provided measures are taken to address mold growth. Such measures to prevent mold growth may include using short inventory pull dates, low pH, antimycotics, coatings, packaging, or any

combination of these measures." "15 In order to achieve a shelf-stable product, a water activity critical limit of 0.85 or lower should be targeted for products stored in an aerobic or oxygen containing environment such as in ambient air, provided the establishment takes steps to prevent mold growth on the finished product. If the product is vacuum packaged in an oxygen impervious packaging (creating an anaerobic environment where no oxygen is present), then the water activity critical limit can be 0.91 or lower. These limits are based on the growth limits for *Staphylococcus aureus* with and without oxygen present (ICMSF, 1996) and FSIS\|u2019 definition of shelf-stability (see the Key Definition in the right panel). According to the International Commission on Microbiological Specifications for Foods (ICMSF), the water activity limit for *Staphylococcus aureus* growth is 0.83 under aerobic conditions and 0.90 under anaerobic conditions. However, as noted in a footnote of that book, this criterion is based on optimal conditions. FSIS recognizes that most jerky type products have other intrinsic factors, such as sodium nitrite, indigenous microflora, and salt concentration, that would also act as barriers to *Staphylococcus aureus* growth. By considering these factors, FSIS recommends an upper limit of 0.85 under aerobic conditions or 0.91 under anaerobic conditions. Establishments that choose to use these limits as support for the shelf-stability of their product may cite this guideline as scientific support for these limits and are not required to provide additional scientific support. Establishments may be able to support other water activity critical limits, provided scientific support is available to support the decision-making. The establishment needs to achieve the water activity of the finished product identified in its scientific support.

**KEY QUESTION** Question: Can a product be labeled as \u201cjerk\u201d if it meets the MPR of 0.75:1 but is not shelf-stable? Answer: No. In order to label a product \u201cjerk\u201d it must be shelf-stable. Although FSIS does not define jerk as shelf-stable in the regulatory standards of identity (9 CFR part 319), consumers consider and expect jerk to be shelf-stable.

**KEY DEFINITIONS** Shelf-stable is the condition achieved when meat and poultry products can be stored under ambient temperature and humidity conditions; if the package integrity is maintained during storage, shipping, and display at retail and in the home; and the product will not spoil or become unsafe throughout the manufacturer\|u2019s specified shelf-life. Water activity, also referred to as aw, is a measure of the concentration of moisture (i.e., water) and its availability in a food. The amount of water available in a food depends on the total concentration of all dissolved substances in the product because they bind water. Thus, if ingredients such as salt or sugar are added to food, they compete with the bacteria for available water. Moisture-protein-ratio (MPR) expresses the percent moisture divided by the percent protein. MPR is commonly used in the U.S. to classify dried sausages and other meat products. Although MPR values indicate the degree of product drying, they are not necessarily indicative of microbial safety or product shelf-stability because they do not take into account availability of the water." "16 NOTE: Vacuum packaged products with a water activity level > 0.85 and \u2264 0.91 should be kept refrigerated once the package is opened because the product would no longer be considered shelf-stable once it is exposed to oxygen. Lack of shelf-stability once the product is exposed to oxygen is mainly a concern for products that would not be consumed within a single serving as these products are not likely to be vacuum packaged by the consumer between servings. Therefore, unless the establishment has support that the product is likely to be consumed in a single serving, vacuum packaged products with a water activity in the range of > 0.85 and \u2264 0.91 should be labeled with a statement such as

\u201cRefrigerate After Opening\u201d (as described in 9 CFR 317.2(k)). Finally, it should be noted that although the establishment may control the water activity level of a product to achieve shelf-stability, controlling water activity alone would not be sufficient to assure the safety of the product. Drying the product does not necessarily result in an adequate reduction of Salmonella organisms because the pathogen can be resistant to drying. For this reason, the establishment should use a validated lethality treatment, as described in Step 5 \u2013 Lethality treatment. \uf0d8 Step 7 \u2013 Post-drying heat step: A post-drying heat step may be added to increase the level of pathogen reduction beyond that achieved by heating alone. This step may be needed for processes that do not result in an adequate reduction of Salmonella through the initial heating process. Adding a post-drying heat step has the potential to reduce Salmonella levels by approximately  $2\log_{10}\u2019s$  from the level of reduction achieved during the initial heat step. One example of a post-drying heat step that has been found to reduce Salmonella levels by approximately  $2\log_{10}\u2019s$  is to heat the dried product in a 275\u00b0F oven for 10 minutes (Harrison et al., 2001). \uf0d8 Step 8 \u2013 Handling: Product is often handled after the lethality and drying steps and prior to\//during packaging. Establishments should control their processes to prevent contamination of product with pathogens from handling after the lethality and drying steps. Such controls should KEY QUESTION Question: Should an establishment use the MPR to determine whether its process produces a shelfstable product? Answer: No. Establishments should use water activity to demonstrate that the product has attained the critical limit for shelf-stability.", "17 include ensuring that cross-contamination of product is minimized before packaging, and ensuring that the product is packaged in such a way that cross-contamination of product post-packaging is also minimized (e.g., with a good seal to maintain package integrity throughout storage, shipment, and display). Preventing cross-contamination is important even if the product is dried to a water activity such that the product is considered shelf-stable. Pathogens may still be able to survive on the product if it becomes contaminated during handling. Cross-contamination of product can occur from situations such as the following: \u2022 Using the same equipment (e.g., preparation tables, scales, or packaging equipment) for both raw and cooked products without completely cleaning and sanitizing the equipment between production lots. \u2022 Placing cooked product on the same surface (e.g., cutting table) as raw product without completely cleaning and sanitizing the surface before reuse. \u2022 Using the same utensils or containers (e.g., scoops or buckets) for both raw and cooked product without completely cleaning and sanitizing the surface before reuse. \u2022 Condensation, aerosolization, or dusting of dry ingredients into the processing environment. \u2022 Employee movement between raw and ready-to-eat areas without hand-washing or garment changing. The establishment is required to maintain sanitation in the RTE area to ensure that food contact surfaces are free of contamination from Lm and other pathogens, such as Salmonella, in accordance with 9 CFR part 430. The establishment is required to develop and implement Sanitation SOPs (9 CFR 416) to ensure that contamination and adulteration of the product is prevented after the lethality treatment. Further guidance on post-processing handling and sanitation for ready-to-eat products including jerky is in the Salmonella Compliance Guidelines for Small and Very Small Meat and Poultry Establishments that Produce Ready-to-Eat (RTE) Products and the Compliance Guidelines to Control Listeria monocytogenes in Post-Lethality Exposed Ready-to-Eat Meat and Poultry Products.", "18 Scientific Support Available for Jerky

Processing Establishments have numerous options for the types of scientific documents that can be used to support that the process achieves adequate lethality. Examples of the scientific support available to help develop a safe jerky process and product are discussed below, along with considerations for each type of support. Product sampling results, based on historical data alone, should not be used as scientific support for a jerky process because they do not provide information on the level of pathogen reduction that is achieved for the process. Compliance Guidelines FSIS has issued a number of different compliance guidelines that have application to jerky processing. It is important to note that, while FSIS considers these documents to be guidelines, if followed precisely, they are considered as validated process schedules because the guidelines contain processing methods already accepted by the Agency as effective in safely producing meat and poultry products. Some considerations for each of these compliance guidelines are outlined on the following pages. \uf0d8 FSIS Appendix A: Compliance Guidelines For Meeting Lethality Performance Standards For Certain Meat and Poultry Products For meat jerky, use of the product time-temperature combinations provided in Appendix A, including those temperatures above 158\u00b0F in which the time for the desired lethality is instantaneous, should help to ensure the safety of the product. These timetemperature combinations are based on experiments that were done with products without added salt or sugar. Added salt, sugar, or other substances that reduce water activity will increase the heat resistance of bacteria in a product. However, time and experience have shown that the time-temperature combinations in the lethality compliance guidelines have been sufficient to produce safe products even with both salt and sugar added, but the humidity during heating is a critical factor. FSIS has found through FSAs and askFSIS questions that there is confusion regarding the humidity options in Appendix A that apply to jerky, when establishments can introduce humidity by continuously introducing steam or sealing the oven, and for how long humidity should be introduced. The humidity options in Appendix A that are applicable to jerky processing are:

- o Heating jerky to a minimum internal temperature of 145 \u00b0F (62.8 \u00b0C) in an oven maintained at any temperature if the relative humidity of the oven is maintained either by continuously introducing steam for 50 percent of the cooking time or by use of a sealed oven for over 50 percent of the cooking time, or if the relative humidity of the oven is maintained at 90 percent or above for at least 25 percent of the total cooking time but in no case less than 1 hour; or
- o Heating jerky in an oven maintained at any temperature that will satisfy the internal temperature and time combinations from the chart provided in", "19 Appendix A if the relative humidity of the oven is maintained at 90 percent or above for at least 25 percent of the total cooking time but in no case less than 1 hour. The relative humidity may be achieved by use of steam injection or sealed ovens capable of producing and maintaining the required relative humidity. In order to introduce humidity by continuously introducing steam or sealing the oven, establishments should:

\uf0fe Cook the jerky product to an internal temperature-time combination of equal to or greater than 145\u00b0F for 4 minutes. It is important to note again that the temperature values in Appendix A correspond to product temperatures, not oven temperatures. If an establishment cooks its jerky product to an internal temperature-time combination of less than 145\u00b0F for 4 minutes, then the relative humidity should be maintained at 90% or above for at least one hour or 25% of the cooking time (whichever is longer). AND \uf0fe Cook the jerky product for at least one hour and in some cases longer. Cooking time should never be less than one hour. Appendix A states that the

relative humidity of the oven should be maintained either by continuously introducing steam for 50 percent of the cooking time or by use of a sealed oven for over 50 percent of the cooking time, but in no case less than one hour. This means that these options should be applied for at least one hour or 50% of the cooking time - whichever is longer. If an establishment can not apply these humidity options for equal to or more than one hour (for example because the lethality treatment takes less than one hour), then the humidity of the oven should be maintained at 90% or above throughout the lethality treatment (not just during the time and temperature combination in Appendix A) with the exception of a surface preparation step Establishments can use the flow chart on the following page to determine the humidity options when using the Appendix A guidelines as scientific support for a jerky process. The times listed in the chart do not include any surface preparation or color setting step where humidity is not introduced. So, if a process includes a 30 minute surface preparation or color setting step, the total cooking time would need to be ≥ 90 minutes in order to continuously introduce steam or seal the oven for at least 1 hour (or 50% of the cooking time, whichever is longer) as specified in Appendix A." , "20 Flow Chart to Identify Humidity Options when Using the Appendix A Guidelines as Scientific Support For a Jerky Process Is the Target Product TimeTemp One of Those in Appendix A that is ≥ 145 °F for 4 minutes? Is the total cooking time longer than 1 hour? Yes No Is the total cooking time less than 1 hour? Yes No At least 90% RH for the entire cooking time No At least 90% RH for at least 1 hour or more\* Steam injection for at least 1 hour or more\*\* Sealed oven for at least 1 hour or more\*\* Choice of \*For processes with cooking times > 4 hours, RH should be 90% for at least 25% of the cooking time which would result in more than one hour. \*\*For processes with cooking times > 2 hours, RH (introduced by steam injection, sealed oven, or at ≥ 90%) should continue to be maintained for at least 50% of the cooking time which would result in more than one hour. At least 90% RH for at least 1 hour or more\*\* Yes", "21 Specific guidance for using the sealed oven option to introduce humidity In order to support that the sealed oven option for introducing humidity is being implemented consistent with the Appendix A guidelines, establishments should: 1)Maintain documentation that supports that the jerky product achieves an internal product time-temperature combination from Appendix A of equal to or greater than 145 °F for 4 minutes. Such documentation could include: a.Records of internal product temperature and time held at that temperature (if applicable); or b.Records of the oven or smokehouse temperature in place of product temperature provided that the establishment has a consistent product and process and has sufficient data correlating the oven temperature selected with the product temperature in the scientific support; 2)Maintain documentation that supports that the oven dampers are closed for at least one hour or 50% of the cooking time - whichever is longer. Such documentation could include: a.Records from a computerized system that contains the time at which the oven dampers were open and were closed; or b.Records of the times at which the oven dampers were open and closed made manually; or c. Records demonstrating the relative humidity level in the oven is maintained for at least one hour or 50% of the cooking time - whichever is longer (e.g., by use of dry and wet bulb thermometers to calculate the relative humidity or use of a humidity sensor that provides a direct measurement) with correlation data supporting a relationship between the relative humidity level in the oven and the time at which the oven dampers were open and closed (see page 23 for guidance on minimum levels of relative humidity\wet and dry bulb temperatures to achieve); 3)Maintain

documentation that supports that when the oven dampers are closed, humidity is maintained in the ovens. Such documentation could include: a. Records demonstrating the relative humidity level in the ovens is maintained (e.g., by use of dry and wet bulb thermometers to calculate the relative humidity or use of a humidity sensor that provides a direct measurement), or b. Data gathered during the initial validation period along with ongoing verification which demonstrates that the relative humidity in the oven is maintained while the dampers are closed; and 4) Have an ongoing procedure for checking that the dampers are properly working along with a maintenance program to periodically monitor that the seals are intact and functional, and that when the oven dampers are closed, a tight seal is obtained. A tight seal is one in which a significant loss of humidity is prevented. FSIS acknowledges that a small amount of smoke or vapors might be seen escaping the smokehouse even when a tight seal is obtained. Establishments should also consider whether there are other openings, particularly in older smokehouses, such as drain valves or air intake valves, that need to be closed in order to ensure that a seal is obtained. Finally, some older ovens may have a stack or other opening that cannot be closed. For those establishments with older ovens that cannot be completely closed, the sealed oven method should not be used. However, the establishment may choose to close what they are able to and add moisture in the system either by continuously introducing steam or another validated method.", "22 Specific guidance for using the continuously injecting steam option to introduce humidity In order to support that the continuously introducing steam option for introducing humidity is being implemented consistent with the Appendix A guidelines, establishments should: 1) Maintain documentation that supports that the jerky product achieves an internal product time-temperature combination from Appendix A of equal to or greater than 145\u00b0F for 4 minutes. Such documentation could include: a. Records of internal product temperature and time held at that temperature (if applicable); or b. Records of the oven or smokehouse temperature in place of product temperature provided that the establishment has a consistent product and process and has sufficient data correlating the oven temperature selected with the product temperature in the scientific support; 2) Maintain documentation that supports that steam is continuously introduced for at least one hour or 50% of the cooking time - whichever is longer. Such documentation could include: a. Records from a computerized system that contains the time at which the steam is turned on and off; or b. Records of the times at which the steam is turned on and off made manually; or c. Records demonstrating the relative humidity level in the oven is maintained for at least one hour or 50% of the cooking time - whichever is longer (e.g., by use of dry and wet bulb thermometers to calculate the relative humidity or use of a humidity sensor that provides a direct measurement) along with correlation data supporting a relationship between the relative humidity level in the oven and the time steam is turned on or a letter from the manufacturer stating that when the relative humidity is rising it is because of live steam injection (see page 23 for guidance on minimum levels of relative humidity\wet and dry bulb temperatures to achieve); 3) Maintain documentation that supports that when steam is injected, humidity is maintained in the ovens. Such documentation could include: a. Records demonstrating the relative humidity level in the ovens is maintained (e.g., by use of dry and wet bulb thermometers to calculate the relative humidity or use of a humidity sensor that provides a direct measurement), or b. Data gathered during the initial validation period along with ongoing verification which demonstrates that the relative humidity in the oven is maintained while steam is being injected. NOTE: The

\u201ccontinuously introducing steam\u201d option refers to the use of live steam, although it may also apply to establishments that spray water onto hot heating elements, which creates steam that in turn produces humidity in the smokehouse. \u201cContinuous\u201d does not mean that the steam is injected for at least one hour during one stage; rather, steam could be injected during stages or time intervals during the lethality (cooking) treatment as long as the total amount of time the steam is introduced adds up to at least one hour or 50% of the cooking time - whichever is longer. Furthermore, the establishment may turn the steam on and off throughout the cooking time when the target humidity is reached. Attachment 4 has an example of a temperature chart, with wet and dry bulb temperatures, that an establishment could use to demonstrate it is meeting the option to continuously inject steam on an ongoing basis using monitoring records.", "23 It is important that establishments maintain and monitor the humidity levels in the oven. Establishments using either the sealed oven or continuously introducing steam options for introducing humidity can support that humidity is being introduced consistent with Appendix A following the guidance on the previous two pages. Establishments do not need to achieve a specific humidity level in the oven if Appendix A is used as the scientific support. However, FSIS recommends that establishments that monitor relative humidity try to achieve a wet bulb temperature of at least 125-130\u00b0F for 1 hour or more along with a corresponding dry bulb temperature needed to achieve at least 27-32% relative humidity or more. FSIS is making this recommendation based on expert opinion and a review of the literature that suggests that the wet bulb temperature should reach at least 125-130\u00b0F for an hour or more during the lethality process, and that at least 27-32% relative humidity should be present to ensure that adequate lethality is attained. Wet bulb temperature is generally a strong indicator of product surface temperature early in the process. Therefore, maintaining the wet bulb temperature at a high enough level to cause lethality (125-130\u00b0F) is recommended (Buege, 2006a; Harper, 2009). Although establishments using either the sealed oven or continuously introducing steam option for introducing humidity are not required to achieve a specific humidity level, the values provided in this document are listed so that establishments have further guidance concerning minimum levels to achieve as recommended by experts at FSIS. Establishments should be aware that achieving a low wet bulb temperature for a short time (i.e., below 125-130\u00b0F for less than one hour) or low relative humidity for a short time (below 27-32% for less than one hour) may indicate that the jerky process may not be achieving sufficient lethality at the product surface which could represent a vulnerability in the establishment\u2019s process to control food safety hazards of concern. NOTE: Achieving a wet bulb temperature of at least 125-130\u00b0F and at least 27-32% relative humidity for 1 hour or more is not adequate on its own to support that the process is being implemented consistently with Appendix A. Rather, establishments should ensure that all critical operational parameters from Appendix A are met (i.e., product time-temperature combination and humidity). Guidance for introducing humidity for the options that require less than 90% relative humidity (continuously introducing steam or sealing the oven) is provided on the previous two pages. Processes for which Appendix A is not appropriate as scientific support Finally, although Appendix A is commonly used as scientific support for jerky processes, the time-temperature-humidity combinations can not be applied in every scenario. For example, establishments should not use Appendix A: \uf0fe To support a process in which the drying step comes before the cooking step. Appendix A was not developed for such processes. \uf0fe To

support a process that uses a home-style dehydrator. The humidity parameters in Appendix A cannot be maintained in a home-style dehydrator. Processes that can achieve an adequate reduction of *Salmonella* and *E. coli* O157:H7 using home-style dehydrators are described in studies by Borowski et al. (2009b), and Harrison et al. (2006).,"24 \uf0d8 FSIS Guidance on Safe Cooking of Non-Intact Meat Chops, Roasts, and Steaks To support the safe production of meat jerk, establishments can use the timetemperature combinations provided in the FSIS Guidance on Safe Cooking of NonIntact Meat Chops, Roasts, and Steaks. Humidity should be considered when using this time-temperature table; therefore, the same options for humidity in Appendix A should be used with this guidance. In addition, the same recommendations regarding maintaining and monitoring humidity for Appendix A apply for establishments that use the FSIS Guidance on Safe Cooking of Non-Intact Meat Chops, Roasts, and Steaks for time-temperature combinations. \uf0d8 Time-Temperature Tables For Cooking Ready-To-Eat Poultry Products To support the safe production of poultry jerk, establishments can use the minimum internal temperatures listed in Appendix A of 160\u00b0F for uncured poultry or 155\u00b0F for cured and smoked poultry. Establishments should not use the time and temperature combinations provided in Appendix A for cooked beef, roast beef, and corned beef for poultry jerk. NOTE: If highly pathogenic avian influenza (HPAI) virus H5N1 is identified as a hazard reasonably likely to occur, cured and smoked poultry should be cooked to at least 158\u00b0F or a time and temperature combination that achieves a 7-log 10 reduction of *Salmonella*. The required reduction of *Salmonella* can also be achieved by using one of the timetemperature combinations listed in the Time-Temperature Tables for Cooking Ready-toEat Poultry Products. As stated in the Time-Temperature Tables guidance document, the tables reflect newer data on the temperatures needed to control *Salmonella* in poultry than the data used in developing Appendix A. The Agency has not rescinded the guidance for poultry in Appendix A, but an establishment needs to take into account the data in the Time-Temperature Tables regarding increased time at a specific temperature to achieve a given level of reduction of *Salmonella*. An establishment that utilizes Appendix A within its process should conduct on-going verification to confirm that the process is being effectively controlled. If an establishment is using Appendix A, and the Agency collects an RTE sample that is positive for *Salmonella*, the establishment would be required under 9 CFR 417.3(b), among other things, to support its decision within its hazard analysis. Regardless of which time-temperature combinations an establishment uses, humidity during heating is a critical factor. As with meat jerk, the time-temperature combinations would be sufficient to produce safe products with both salt and sugar additives if the processor uses the humidity parameters applicable to beef as described in Appendix A. The same recommendations regarding maintaining and monitoring humidity for Appendix A apply for establishments that use the Time-Temperature Tables for Cooking Ready-to-Eat Poultry Products."25 Journal articles Journal articles are a primary type of support used for jerk processes. A number of studies have been conducted to determine time-temperature-humidity combinations that result in adequate lethality for jerk. Attachment 2 contains a summary of timetemperature-humidity combinations, along with other critical operational parameters from published studies that have been found to result in adequate lethality. If an establishment chooses to use a journal article as scientific support, it should ensure that all of the critical operational parameters (i.e., product time-temperature combination and relative humidity) used in the study match those used in the actual process. If one or more of the parameters are

not addressed or do not match the level used in the support, then the establishment's process may not achieve the same level of lethality as cited in the journal article. In that case, the establishment should document a justification as to why that parameter does not need to be met or measured, or why it differs from the support. When identifying a journal article, the establishment should consider whether it is using the same: Product (e.g., species, type-whole muscle or ground); Product formulation; Product time-temperature combination; Relative humidity at each stage (including, if reported, using the same humidity levels at the beginning and end of each stage); Type or pH of marination (if applicable); and Smoke (if applicable) as used in the article. The establishment should also ensure that the composition of the product (% salt, % fat) used in the study is the same as the composition of the actual product being produced. A prudent establishment should have knowledge of the products it produces. Because meeting the critical operational parameters is essential to achieve lethality in the product, the parameters used or measured in the article should be addressed in the process.","26 KEY QUESTION Question: Can an establishment's process use a different level of a critical operational parameter (for example, a higher concentration of an antimicrobial or a higher processing temperature) than what was used in the scientific support? Answer: Generally, establishments should use the same critical operational parameters as those in the scientific support. In some circumstances, establishments may be able to support using critical operational parameters (e.g., higher concentrations of antimicrobials or higher thermal processing temperatures) that are different from those in the scientific support. In these cases, establishments should provide justification supporting that the levels chosen are at least as effective as those in the scientific support. This justification is needed because higher levels of a critical operational parameter may not always be equally effective. For example, antimicrobial agents may only be effective within a range of concentration after which point efficacy may decrease. Similarly, higher processing temperatures may result in the surface of the product drying out before adequate lethality is achieved. In addition to ensuring that the levels chosen are at least equally as effective, establishments should ensure the levels are also safe and suitable (FSIS Directive 7120.1 Safe and Suitable Ingredients Used in the Production of Meat and Poultry Products and 9 CFR 424.21(c)). Key Considerations for Journal Articles in Attachment 2 Attachment 2 contains a summary of processes, and the critical operational parameters of those processes, that have been found to achieve adequate lethality for jerky in the published literature. The Attachment is provided to help establishments identify alternatives to the Appendix A guidelines. This Attachment is not considered adequate support on its own because it does not provide the details of each study that an establishment needs to determine if the study is representative of the actual process. For this reason, if an establishment chooses to use one of the articles provided in Attachment 2 for scientific support, the establishment will need to have a full copy of the original article on file.","27 Challenge Studies In cases where an establishment's process does not match available scientific support documents, such as a Compliance Guideline or published journal article, an establishment may decide to conduct an inoculation challenge study to support that its process achieves adequate lethality (e.g., for meat and poultry jerky at least a 5.0-log<sub>10</sub> reduction of *Salmonella* spp.). A challenge study is a study that documents the adequacy of control measures in a process. Obtaining this documentation involves inoculating the target organism (e.g., *Salmonella* spp. or an appropriate surrogate organism such as certain

Pediococcus strains) into a product to determine the effect of control measures such as cooking and drying to reduce the organism. Challenge studies should be conducted by a microbiologist trained in performing challenge studies in a laboratory to avoid the possible spread of contamination in an establishment. In a challenge study, the number of organisms before and after the application of the control measure is counted to determine the effect of the control measure. The challenge study should be designed to closely match the critical operational parameters (e.g., time, temperature, and relative humidity) in the establishment's actual process. Challenge studies should be based on a sound statistical design and should also employ positive and negative controls. As recommended by the National Advisory Committee on Microbiological Criteria of Foods (NACMCF), the number of samples to be analyzed initially and at each time interval during processing or storage should be at a minimum two; however, analysis of three or more samples is preferred. Replicates should also be conducted. Replicates should be independent trials using different batches of product and inoculum to account for variations in product, inoculum, and other factors. Generally, the number of samples and replicates should be increased in situations of higher variability or uncertainty. When the number of samples analyzed at each time interval is only two, it is better for the study to be repeated (replicated) more than two times. In studies with three or more samples tested at each time interval, two replicates are usually adequate. In addition, the inoculum level should be at least two logs greater than the log reduction to be demonstrated. FSIS recommends that establishments use *Salmonella* (or an appropriate surrogate of *Salmonella*) as an indicator of lethality because it tends to be more heat resistant than other pathogens (Goodfellow & Brown, 1978; Line et al, 1991). FSIS considers all *Salmonella* serotypes to be pathogens of public health concern. At a minimum, a study for a microbiological food safety hazard should identify: "The hazard (including the specific strains studied), The expected level of hazard reduction or prevention to be achieved, The processing steps that will achieve the specified reduction or prevention, All critical operational parameters or conditions (e.g., time, temperature, and humidity) necessary to achieve the reduction, How these processing steps/parameters can be monitored, The critical ingredients (e.g., salt, sugar, and cure), and The critical product characteristics (e.g., pH, water activity, and fat content)." "28 FSIS does not require establishments to validate that their process achieves reduction in *E. coli* O157:H7 or Lm if they achieve sufficient reductions in *Salmonella* because *Salmonella* is an indicator of lethality. Without further scientific support, establishments should not use pathogens other than *Salmonella* as indicators of lethality. For example, establishments should not use reductions in Lm to support similar reductions in *Salmonella* without support that Lm is at least equally as heat resistant as *Salmonella* under the conditions being studied. If an establishment chooses to conduct a challenge study in a testing laboratory, the study should use at least five strains of *Salmonella*, including strains associated with human illness and strains isolated from meat and poultry products. Ideally, some of the strains selected should be those with known heat-resistance properties. One good choice, for example, might be *Salmonella enterica* serovar Senftenberg strain 775W, which displays heat resistance properties (Ng et al., 1969). *Salmonella enterica* serovar Senftenberg occurs in the top 10 serotypes seen in FSIS testing for both cow/bull carcass testing and ground beef, as well as in turkeys (carcass and ground) (FSIS testing data, 2012), so it would also be an appropriate choice for what might be seen in these products being tested. If an establishment chooses to conduct a challenge

study in a plant environment, to best represent actual processing conditions for example, then the establishment should choose surrogate organisms that have been found to respond similarly to the pathogens of interest (e.g., *Salmonella*, and if applicable, *E. coli* O157:H7). For example, the University of Wisconsin has conducted research with ground-and-formed jerky and found that two *Pediococcus* strains (Saga 200 and Biosource) have similar heatresistance to *Salmonella* and can be used in in-plant validation studies (Borowski et al., 2009a). FSIS has identified four surrogate organisms that have been shown to respond similarly to *E. coli* O157:H7 during cooking (the following askFSIS Q&A has more information) for use in in-plant validation studies. For the reasons explained above, establishments also should not use surrogate organisms that have been shown to respond similarly to *E. coli* O157:H7 to support similar reductions in *Salmonella* without support that the organisms are at least as heat resistant as *Salmonella*. Challenge studies should be equivalent to peer-reviewed scientific literature. All of the critical elements listed above for a study above need to be included to permit evaluation or confirmation of the results. More information on conducting challenge studies is found in the article published by the National Advisory Committee on Microbiological Criteria for Foods (NACMCF) in the Journal of Food Protection in 2010.," "29 References Borowski, A.G., Ingham, S.C., Ingham, B.H. 2009a. 1. Need for guidance Comment: One commenter questioned the need for the guidance given the limited information publicly available on the causes of past outbreaks in jerky and the importance of humidity in the production of jerky. The commenter also identified a broken link to a reference to one of the past outbreaks in the 2012 version of the guidance. Response: FSIS initially issued this guidance in 2007 to clarify the importance of introducing humidity to jerky processors given the lack of humidity control identified in past outbreaks. One potential cause of the 2003 Salmonella Kiambu outbreak in jerky was the very slow drying process under low humidity conditions (1% RH - 82\u00b0C dry bulb, 30\u00b0C wet bulb), which allowed Salmonella organisms to dehydrate during drying and become resistant to heat. This information was gathered by FSIS during the course of the investigation. Research has demonstrated that bacteria can become more heat resistant as their moisture level decreases, and increased concentrations of solutes, especially sugars, increase the heat resistance of bacteria. Therefore, drying of the product surface before the pathogens are destroyed will increase pathogen heat resistance and allow them to survive the heating process. By incorporating humidity to minimize evaporation, the D values (time at a constant temperature necessary to destroy 90% or 1-log10 of the target organism) that are the basis for Appendix A and other scientific support documents remain valid (Goepfert, 1970; Goodfellow and Brown, 1978; Faith, N.G. et al. 1998). For this reason, the low humidity conditions were considered to be a plausible cause of the outbreak. The low humidity conditions were likely related to the location of the processing establishment in Albuquerque, New Mexico, which is at an elevation of greater than 4,000 feet<sup>2</sup>. As described on page 13 of the guidance, the relative humidity in the ambient (or room) air is lower at higher altitudes, which affects the relative humidity in the smokehouse chamber. Prior to the 2003 outbreak, at least six other salmonellosis outbreaks occurred in New Mexico between 1966 and 1995 suggesting the high altitude\low ambient humidity conditions in the state played a role, among other factors (CDC, 1995; Eiden, 2000). Since the 2003 outbreak, FSIS has continued to refine the guidance document based on the most upto-date science and lessons learned from FSAs. Finally, the broken link provided in the previous version of the guideline has been replaced with a functioning link to an Epidemiology Presentation from the New Mexico Department of Health

(<http://aces.nmsu.edu/ces/nmhs/documents/albanese.pdf>). Comment: One commenter questioned why the Jerky Compliance Guidelines focused on small and very small establishments. According to one commenter, small and very small meat processors in the U.S. represent 5 percent of the total meat production volume, but 95 percent of the total meat processing businesses in the U.S. 2

<http://egsc.usgs.gov/ib/pubs/booklets/elvadist/elvadist.html>", "33 This commenter suggested that the guidelines not be limited to small and very small establishments but rather should be addressed to the whole industry. Response: FSIS focused the Jerky Compliance Guidelines on small and very small establishments in support of the Small Business Administration\u2019s initiative to provide small and very small establishments with compliance assistance under the Small Business Regulatory Flexibility Act (SBRFA). However, all

FSIS regulated meat and poultry establishments may be able to apply the recommendations in this guidance. It is important that small and very small establishments have access to a full range of scientific and technical support, and the assistance needed to establish safe and effective HACCP systems. Although large establishments can benefit from the guidance that FSIS provides, focusing the guidance on the needs of small and very small establishments provides them with information that may be otherwise unavailable to them because of cost. For example, FSIS included growth limits for *Staphylococcus aureus* published in an ICMSF book chapter. Establishments can reference this guideline for support for the development of critical limits based on these values instead of having to purchase the costly textbook. FSIS also included an inexpensive way for establishment\u2019s to make their own wet bulb in

Attachment 3 courtesy of University of Wisconsin-Madison Center for Meat Process Validation.

2. Validation Comment: One commenter recommended FSIS postpone the release of the finalized guidance document until the finalized HACCP systems validation guidance document is released to ensure the documents are cohesive and complete. Response: This Compliance Guideline articulates how industry can meet FSIS requirements regarding jerky processing as well as FSIS recommendations to help produce a safe product based on the scientific information available in the literature. The primary focus of this guidance document is on the first element of validation: scientific support. This element includes the process of identifying scientific support documents that closely match the establishment\u2019s actual process along with identification of the critical operational parameters from the scientific support relevant to the establishment\u2019s process. FSIS is currently enforcing this element of the initial validation requirement (9 CFR 417.4(a)(1)). In addition, FSIS does not wish to delay finalizing this document because it reflects the most up-to-date science and understanding of jerky processing and addresses key issues FSIS has identified through FSAs and response to outbreak investigations. FSIS is sharing this information in a timely manner in order to help establishments produce a safe product. Comment: One commenter expressed concern with the following \u201cKey Question\u201d in the guidance document: \u201cCan an establishment\u2019s process use a different level of a critical operational parameter (for example, a higher concentration of an antimicrobial or a higher processing temperature) than what was used in the support document?\u201d. The commenter provided an example of shelf-stable jerky that has a water activity of 0.85 or less. In the example, some processors may reduce the water activity lower than 0.85 for quality issues or an extended shelf life. The commenter expressed concern that establishments would have to provide a justification for the lower water activity level chosen.\",\"34 Response: FSIS has found through FSAs that establishments use levels of critical operational parameters that are different from those in their scientific support without any consideration as to whether this will result in the same efficacy demonstrated in the scientific support. The Agency is recommending that establishments provide a scientific justification as to why the same efficacy would be achieved with a different level of a critical operational parameter. In the example provided by the commenter, an establishment could provide the justification, with reference to applicable scientific support, that pathogen growth decreases as water activity decreases, supporting that if 0.85 is adequate to preclude growth, then a lower water activity would also preclude growth of pathogenic microorganisms. Such a justification would be adequate and could be maintained in the establishment\u2019s decision-making documents as scientific support for the process

used. Comment: One commenter indicated that the guidance document is not specific enough in explaining how closely scientific support must match an establishment's process, species, or products. In addition, the commenter stated that inspection program personnel would find noncompliance with the validation regulations simply because the supporting document does not match the establishment's production precisely. Response: FSIS is not prescriptive in terms of how closely the scientific support should match the actual process. Rather, FSIS recommends that the critical operational parameters used in the scientific support be consistent with those used in the establishment's process and is providing establishments the flexibility to use different levels as long as a scientific justification is provided. FSIS inspection program personnel (IPP) verify establishment validation when performing the Hazard Analysis Verification (HAV) task. Instructions for performing the HAV task are provided in FSIS Directive 5000.6 Performance of the Hazard Analysis Verification (HAV) Task and in the HAV section of the Inspection Methods training. FSIS will issue additional instructions to its field personnel for them to verify that establishments meet all validation requirements once the FSIS HACCP Systems Validation Guidance is finalized. Comment: One commenter stated that the type of equipment used in the process should not be considered a critical operational parameter. Response: FSIS has found through FSAs that establishments use different types of equipment than that used in the scientific support without any consideration as to whether this change will result in the same efficacy demonstrated in the scientific support. The type of equipment, such as a smokehouse, could influence the ability to implement other critical operational parameters such as humidity. FSIS is recommending that establishments consider the type of equipment as a critical operational parameter so that establishments take into account whether changes in equipment affect the implementation of other critical operational parameters. This consideration should be a part of the initial set-up of the system and would not need to be done on an on-going basis unless changes to the equipment are made.

3. Step-by-step guide for jerky processing", "35

Comment: Two commenters stated that Steps 2 (Marination) and 3 (Interventions) in the 2007 and 2012 versions of the guidance are not commonly used steps in the industry. Response: FSIS recognizes that not all processes may include the same steps listed in the step-by-step guide. FSIS included steps such as intervention in the guidance because some heating processes may not deliver an adequate lethality and, thus, may require an additional intervention step to ensure product safety. To more accurately reflect commonly used processing steps, FSIS has included the surface preparation step (now Step 4) in the guidance, which is a commonly used step in which strips are heated using a low temperature heat step to make the surface tacky, thus aiding in smoke adherence and improving product texture.

Comment: Two commenters stated that steps 5 (drying) and 6 (post-drying heat step) in the 2007 and 2012 versions of the guidance should be combined because they are often performed as single step by processors. Response: Although the steps may be combined, in a processing schedule, for example, these steps are listed separately for purposes of the guidance document to provide information to establishments on the use of a post-drying heat step for processes that do not result in an adequate reduction of *Salmonella* through the initial heating process. Adding a post-drying heat step has the potential to reduce *Salmonella* levels by approximately  $2\text{-log}_{10}$ s from the level of reduction achieved during initial heat step.

4. Lethality treatment

Comment: One commenter questioned the recommendation that the lethality treatment of meat jerk should

achieve at least a 5.0-log10 reduction of *Salmonella* spp. when there is no USDA\FSIS performance standard specifically for this product. Response: Jerky producers (and all producers of RTE product) are required to control the food safety hazards in their products (9 CFR 417.4(a)) and document that their HACCP systems work according to 9 CFR 417.5(a). For RTE products, this requirement means that, among other controls, the establishment needs to achieve lethality of pathogens (e.g., *Salmonella*) in the product. In the FSIS *Salmonella* Compliance Guidelines for Small and Very Small Meat and Poultry Establishments that Produce Ready-to-Eat (RTE) Products, FSIS recommends that processors achieve a 5log10 reduction of *Salmonella* in such meat products as jerky to produce a product safe for consumption. This recommendation is based on expected levels of *Salmonella* in raw products. The compliance guideline also provides alternative forms of lethality that establishments may use. Establishments producing a RTE product must provide adequate scientific support that the process for the RTE product will not result in an adulterated product. In addition, FSIS tests ready-to-eat product for *Salmonella* (as well as *Listeria monocytogenes*) to verify that establishments are addressing the pathogen.

5. Highly pathogenic avian influenza Comment: Two commenters disagreed with the following statement: \u201clf highly pathogenic avian influenza (HPAI) virus H5N1 is identified as a hazard reasonably likely\,"36 to occur, cured and smoked poultry should be cooked to at least 158\u00b0F or a time and temperature combination that achieves a 7-log reduction of *Salmonella*.\u201d The commenters stated that if this statement is included in this guidance document, establishments will now have to reassess all their HACCP plans if inspection personnel interpret it as a requirement. Response: This statement has appeared in previous versions of the jerky compliance guidance document. The Agency has not required establishments to reassess their HACCP plans for highly pathogenic avian influenza and does not intend to do so at this time. This information has been included as guidance in the event that an establishment identifies HPAI virus H5N1 as a hazard reasonably likely to occur.

6. Humidity Comment: One commenter disagreed with the following statement: \u201cOne way for an establishment to know that the product has not dried out before a lethal timetemperature combination is attained is to measure the water activity of the product after the lethality treatment but before drying.\u201d The commenter stated that this is not necessary if the humidity requirements are achieved. The commenter also said the guideline should clearly state that lethality should be achieved prior to drying the product to achieve desired quality and water activity for shelf stability. Response: FSIS has added the following clarifying information: \u201cAlthough this information may provide useful information to an establishment, such data are not needed if an establishment is following procedures to achieve the relative humidity in the scientific support.\u201d

Comment: One commenter disagreed with statements in the guidance document that establishments should monitor humidity throughout the entire lethality treatment. The commenter stated that establishments could conduct some sort of 90-day validation of their thermal processing schedules to achieve confidence that humidity was properly addressed. Response: As stated on page 13, FSIS recommends that establishments monitor relative humidity using wet and dry bulb thermometers or a humidity sensor with every lot or batch of product although FSIS does not require this monitoring frequency. It is the responsibility of the establishment to support its monitoring procedures and frequencies. However, inadequate or inaccurate recordkeeping (e.g., data entry error or unclear monitoring records) has contributed to jerky product recalls,

particularly when such records were associated with a lack of information regarding the implementation of all of the critical operational parameters for each batch or lot produced.

Comment: One commenter recommended that FSIS remove the following statement related to Appendix A: \u201clf an establishment cannot apply these humidity options for equal to or more than one hour, then the humidity of the oven should be maintained at 90% or above throughout the lethality treatment.\u201d Response: The option in Appendix A that allows for humidity levels less than 90% is as follows:

\u201cHeating roasts of any size to a minimum internal temperature of 145 \u00b0F (62.8 \u00b0C) in an oven maintained at any temperature if the relative humidity of the", "37 oven is maintained either by continuously introducing steam for 50 percent of the cooking time or by use of a sealed oven for over 50 percent of the cooking time, or if the relative humidity of the oven is maintained at 90 percent or above for at least 25 percent of the total cooking time, but in no case less than 1 hour.\u201d The final clause \u201cbut in no case less than 1 hour\u201d means that the humidity options of continuously introducing steam or sealing the oven should be applied for at least 1 hour. FSIS recognizes that jerky is a small mass product that often has total cooking times of less than 1 hour. Appendix A, and that the additional humidity options were originally designed for large mass products with longer cooking times. In cases where these humidity options can not be applied for at least 1 hour, the establishment should apply at least 90% humidity throughout the cooking time (even if the cooking time is less than 1 hour) in order to use Appendix A as scientific support and to ensure product reaches a lethal temperature and does not dry out before lethality is achieved.

Establishments have flexibility to use other scientific support if they are unable to meet the critical operational parameters. FSIS clarified this issue in the guidance. Comment: FSIS received one question through askFSIS inquiring whether reference to the cooking time in the humidity options in Appendix A refers to the entire cooking time (including come up time) or just the time during which the temperature in Appendix A is achieved and maintained (e.g., 145\u00b0F for 4 minutes). Response: As stated on page 7, the cooking time (also referred to as the lethality treatment) includes the time when the thermal processing begins (e.g., the product is placed in the heated oven) until the time the product reaches the desired lethality time-temperature combination from Appendix A. Therefore, if an establishment is applying humidity by continuously introducing steam for 50% of the cooking time, but in no case less than 1 hour, 50% of the cooking time should be calculated based on the total cooking time, not just the time during which the temperature in Appendix A is achieved and maintained. If humidity is not applied early in the process, evaporating water will absorb the heat and a lethal temperature will not be achieved. Comment: One commenter disagreed with the statement:

\u201cEstablishments using the option to continuously inject steam should also have a procedure or mechanism in place to ensure that steam is being continuously injected\u2026.\u201d The commenter indicated that smokehouses do not operate this way, and that if a program is set for 40% relative humidity, the smokehouse may spray water on the heating element to achieve this 40% relative humidity. If the smokehouse reads that the house has, for example, 50% relative humidity, it will stop spraying water on the heating elements and the dampers will fluctuate to achieve the desired 40% relative humidity in the smokehouse.

Response: FSIS recognizes that steam may be turned on and off throughout the cooking time when the target humidity is reached and has included this approach in the guideline. Some of the supporting documentation that can be used to demonstrate that steam is being

\u201ccontinuously introduced\u201d is illustrated in Attachment 4. 7. Ambient vs. smokehouse temperatures Comment: One commenter requested further explanation of the effects of ambient temperature on the smokehouse or oven temperatures. The commenter also", "38 requested that FSIS acknowledge that smokehouses\ovens cannot be completely sealed. Response: FSIS has provided additional information on page 12 regarding the role relative humidity in the ambient air plays on the relative humidity in the smokehouse or oven. FSIS has also provided clarification on page 21 that, even when a tight seal is obtained, some loss of humidity is the form of minor smoke or vapors may be seen. 8. Reference to International Commission on Microbiological Specifications in Foods (ICMSF) (1996) Microorganisms in Foods 5 Comment: Two commenters expressed concern that establishments will use the ICMSF book chapter in place of Appendix A. Response: The only reference to the ICMSF book made in this guidance document is provided as support for finished water activity limits in order to support product shelf-stability. It would not be acceptable for an establishment to cite the water activity critical limits or the ICSMF book chapter as support for a lethality or drying process because meeting a specific water activity level does not support that a 5-log<sub>10</sub> reduction is achieved. In general, establishments should not use finished product water activity levels alone as support that a product is RTE. The reason is that low water activity alone, without a further heat treatment, would not necessarily result in adequate reduction of *Salmonella* because the pathogen is known to be resistant to drying. This issue has been clarified and addressed in this guidance on page 15. Comment: One commenter stated that FSIS should not provide specific guidance on water activity values that can be used to support shelf-stability by an establishment within the guidance. The commenter indicated if FSIS provides one specific number in any guidance document, industry or FSIS may consider the guidance a requirement. Response: FSIS has found through askFSIS questions and FSAs that establishments are not maintaining adequate scientific support that products are shelfstable. Therefore, water activity values are provided as guidance to provide small and very small establishments with compliance assistance under SBRFA. However, establishments have flexibility in terms of selecting and supporting the critical limits of their process and are not required to use the limits provided. FSIS has made clear that this document is guidance and is not establishing new requirements (see page 2) Comment: One commenter requested a rationale for the guidance provided on water activity limits to support shelf-stability for products packaged under aerobic and anaerobic conditions because the limits are different than those in the ICMSF book chapter. The commenter also pointed out that the citation for the ICMSF book chapter referenced the wrong page. Response: The water activity limits of 0.85 under aerobic conditions and 0.91 under anaerobic conditions provided in this document are based on the definition of shelf-stability in the guidance on page 15 and the growth limit of *Staphylococcus aureus* in the ICMSF Book chapter (Page 304 Table B). The definition of shelf-stability in the guidance is stated as the \u201ccondition achieved when meat and poultry products can be", "39 stored under ambient temperature and humidity conditions; if the package integrity is maintained during storage, shipping, and display at retail and in the home; and the product will not spoil or become unsafe throughout the manufacturer\u2019s specified shelflife. \u201c Under this definition, no growth of pathogenic organisms occurs. According to the ICMSF book chapter, the limit of growth for *Staphylococcus aureus* is 0.83 under aerobic conditions and 0.90 under anaerobic conditions. However, as noted in the footnote of the book, this criterion

is based on optimal conditions. FSIS recognizes that most jerky type products have other intrinsic factors such as sodium nitrite, indigenous microflora, and salt concentration that would also act as barriers to *Staphylococcus aureus* growth. By considering these factors, FSIS has recommended an upper limit of 0.85 under aerobic conditions or 0.91 under anaerobic conditions. This rationale is now provided in the guidance document. The guidance document also now clarifies that these factors may be used to consider a product stable provided the establishment takes steps to prevent mold growth on the finished product. Finally, FSIS revised the reference to include the page number of the specific table containing these values.

Comment: One commenter expressed concern that the ICMSF book chapter used as the reference for the limits of growth of *Staphylococcus aureus* under aerobic and anaerobic conditions does not contain microbiological data supporting the limits. Response: FSIS considers information found in textbooks and other scientific texts as acceptable scientific support because this type of scientific data goes through a process of evaluation involving qualified individuals within the relevant field. Often textbooks and other scientific texts contain a summary of information based on other peer-reviewed published research, as is the case with the ICMSF book. In the case of the water activity values provided in this guidance, establishments can refer to the guidance and are not required to provide a copy of the ICMSF book chapter or the original research referred to in the book because this guidance document contains the critical operational parameter (water activity).", "This Attachment is not considered adequate support on its own because it does not provide the details of each study an establishment needs to determine if the study is representative of the actual process. 40

(2006)10 Beef jerky strips Yes No 143.6 8-9 33 >6 >6","49 Attachment 3: Making Your Own Wet Bulb Thermometer (Reprinted with permission) By G. Burnham, S.C. Ingham and B.H. Ingham University of Wisconsin-Madison Center for Meat Process Validation If you are smoking or drying meat, there are several parameters to monitor which will help you control your process: dry bulb temperature, wet bulb temperature, and relative humidity. Research at the University of Wisconsin Center for Meat Process Validation has shown that monitoring wet bulb temperature is even more important (and much easier!) than monitoring product temperature during your process. Since wet bulb temperature is critical to process monitoring, this document describes how to easily, and perhaps inexpensively, construct a wet bulb thermometer. Dry bulb temperature, usually referred to as air temperature, is the smokehouse\oven property that is most commonly measured by jerky-makers. When people refer to the temperature (heat content) of the air, they are normally referring to the dry bulb temperature. It is called \"dry bulb\" because the air temperature is indicated by a thermometer that is not moistened and will not be affected by evaporative cooling. Wet bulb temperature is the temperature indicated by a moistened thermometer bulb exposed to air. A wet bulb thermometer measures the extent of cooling that happens as moisture dries from a surface (evaporative cooling). The wet bulb temperature is always lower than the dry bulb temperature except when there is 100% relative humidity. Because evaporative cooling occurs on the surface of thin jerky strips, the wet bulb temperature is more accurate measurement of

product temperature. We developed a wet bulb thermometer (WBT) which is easy to assemble and economical for a meat processor to use. To begin assembling a wet bulb thermometer, you will need to determine what type of temperature measuring device you will use. You will need to use a temperature recorder with a \u201ctip reading\u201d probe\u201c/wire\u201d/stem. Either an instant read or a data-logging temperature measuring device will work; both are pictured in image 1. A - 3 styles of \u2018instant read\u2019 temp- A B 1 erature measuring device B - a data logger-style of temp- erature measuring device In each case, the \u2018tip reading\u2019 probe\u201c/wire is circled. Instant read temperature recorders. (A) An instant read temperature Recorder will offer immediate feedback, with the temperature displayed on the front of the unit. However, data may not be recorded with this type of unit; the processor must record the data periodically. See page 51 for more information on ordering instant-read temperature recorders.", "50 A data logger-style temperature recorder. (B) This type of device keeps track of, or \u2018logs\u2019 temperature over a period of time. An inexpensive data logger usually does not offer immediate readout of data. A processor must connect the data logger to a computer to view the temperature data. A data logger does, however, offer a continuous record of temperature history which can be important for HACCP documentation. See page 51 for information on ordering a standard data logger. Once you have your temperature recorder, you will need to choose material to serve as the \u201cwick\u201d to cover the tip probe. Water evaporating from the wick will reduce the temperature recorded, giving an indication of evaporative cooling. The wick should be made from an absorbent material, preferably cotton. It should also be constructed of two phases: a loose, absorbent interior, and an exterior that is of an absorbent tighter meshing material. The exterior keeps the inner absorbent material around the sensing portion of the temperature probe and prevents the sensing portion of the recorder from being exposed to direct ambient conditions. You may wish to purchase wicks commercially, such as from an online supplier

(<http://www.wickstore.com/wetbulbwick.html>), or a good substitute is a round cotton bootlace (image 2). See page 51 for more information on supplies for a wet bulb thermometer. There are several simple steps to setting up a wet bulb thermometer. 1. Gather materials. You will need a vessel for holding water which must either be refilled during processing, or must be sufficiently large to hold enough water (allowing for evaporation) to keep the water level close to the temperature probe. Choosing a vessel with a small diameter opening will reduce evaporation. Once a water vessel has been chosen, simply fill it with water. You will also need a temperature measuring device and material to serve as a wick. In image 3, the bottom of a soda bottle 2 and a glass beaker are pictured as vessels. 3 Both an instant read and a data logger are shown for measuring temperature and pieces of brown cotton shoelace serve as the wick. 2. Assemble the wet bulb thermometer. Cut a portion of the wicking material (it should be long enough to reach the bottom of the water vessel and than some). Connect the sensing portion of your temperature recorder to the wick by inserting the probe\u201c/wire\u201d/stem into the center of the wick (image 2). Secure the end of the wick to the probe\u201c/wire\u201d/stem using tape. 4 Place the wick in the water-containing vessel. Make sure the wick is completely", "51 saturated with water, then position the wick-covered sensing portion of your temperature recorder so that it is completely exposed to ambient conditions, yet as close as possible to the water source (image 4). This will ensure adequate wicking of the water to the sensing portion of the temperature recorder. If exposure to ambient conditions is too great, such as when the wick is too long or

the recorder too far from the water surface, the wick may dry out, and evaporative cooling will not be recorded. 3. Place the wet bulb thermometer inside the chamber. If you are using an instant reading temperature measuring device to make process adjustments, place the wet bulb thermometer for easy access and readability, such as near a door or window (image 5). If immediate feedback is not a consideration (image 6), place the device where the ambient conditions of your process are least likely to give you optimum conditions 5 - hence a \u201cworst case\u201d reading. Position the wet bulb thermometer in a flow of air (such as in a stream of incoming air), but away from fans which will cause excessive evaporation and drying of the wick. 4. Record wet bulb temperature. Establish a regular schedule of recording or down-loading wet bulb temperature. Check water level in the vessel periodically, and also check the position of the wick. The portion of the wick above the water must remain moist for accurate temperature measurement. The wet bulb temperature can be used to adjust your process conditions, as needed. For more information contact: Steve Ingham, Extension Food Safety Specialist (608) 265-4801, scingham@wisc.edu May, 2006 The University of Wisconsin-Madison Center for Meat Process Validation provides science-based HACCP support to small meat processors in meeting state and federal mandates for safe food processing and handling. For more information on the Center contact Dr. Steve Ingham, 1605 Linden Drive, UW-Madison, Madison, WI 53706 (608) 265-4801 Email: scingham@wisc.edu", "Cooking Program and Recorder Chart Courtesy of: Dr. Jeff J. Sindelar; Meat Science & Muscle Biology Lab, University of Wisconsin-Madison & Robert Hanson; HansonTech, LLC 53 Attachment 4: Example Time-Temperature Recorder Chart to Support Option to Continuously Inject Steam The chart on the next page illustrates and supports that steam is being continuously introduced into the smokehouse for at least 50% of the cooking time but in no case for less than one hour per Appendix A. The smokehouse schedule is provided for reference below. As can be seen on the recorder chart, during the cooking time (that is the first hour of the process), the wet bulb rises while humidity (in the form of steam) is continuously injected. The process eventually achieves and maintains a wet bulb of 150oF, which at a dry bulb temperature of 170oF equates to a relative humidity of 59%. The process targets an internal product temperature of 145oF for 4 minutes per Appendix A. Cooking program for beef jerky Stage Type Time Dry Bulb Wet Bulb Dampers Notes 1 Cook 60 min 170oF 150oF Closed Humidity continuously injected 2 Dry 120 min 150 --- Closed 3 Dry 80 min (to aw) 150 --- Open In addition to supporting that steam is being continuously introduced, the chart provides a good illustration of why wet bulb temperature is a better indicator of product internal temperature than dry bulb temperature. As can be seen on the chart, the product

internal temperature (shown by the yellow line), follows the wet bulb temperature (shown by the blue line) more closely than the dry bulb temperature (shown by the dark red line) during the lethality treatment. Towards the end of the process, the product internal temperature breaks above the wet bulb temperature and rises towards the dry bulb temperature as a result of diminishing evaporative cooling of the jerky that occurs because the product is drying out (i.e., moisture has been lost) (Buege et al., 2006a).", "Cooking Program and Recorder Chart Courtesy of: Dr. Jeff J. Sindelar; Meat Science & Muscle Biology Lab, University of Wisconsin-Madison & Robert Hanson; HansonTech, LLC 54 Temperature profile for beef jerky process during cooking and drying Sliced whole muscle beef jerky, 0.125\" thick 40 50 60 70 80 90 100 110 120 130 140 150 160 170 180 190 200 0 1 2 3 4 5 time (hr) Temperature (F) DryBulb Temperature WetBulb Temperature Jerky Temperature Stage 1. Wet-surface lethality step. Steam is continuously injected from the beginning of the process to achieve and maintain a wet bulb of 150oF. Stage 2. Jerky dried with sealed intake\exhaust dampers. Wet bulb temperature slowly decreases from 140 to 130oF. Evaporative cooling causes the jerky temperature to closely follow the wet-bulb temperature. Stage 3. Intake and exhaust dampers are opened and wet bulb temperature drops. Drying accelerates and jerky temperature breaks above the wet bulb temperature."], {"file\_name": "FSIS\_GD\_2014\_0011", "title": "Compliance Guidelines for Shiga toxin Escherichia coli (STEC) Organisms Sampled and Tested Labeling Claims for Boneless Beef Manufacturing Trimmings (\u201cBeef Trim\u201d)", "num": "FSIS-GD-2014-0011", "id": "0181dd3bec74885e8af19d08695d33ffb28cf30e8a799ff24e82fb8351d50a00", "corp\_us": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/import/Compliance-Guide-Ecoli-Tested-Claims.pdf", "type": "pdf", "n\_pages": 8, "word\_count": 2829, "text\_by\_page": ["Compliance Guidelines for Shiga toxin Escherichia coli (STEC) Organisms Sampled and Tested Labeling Claims for Boneless Beef Manufacturing Trimmings (\u201cBeef Trim\u201d) August 2014 I. Purpose of the Labeling Guidance This document provides guidance on the use of labels bearing an FSIS sketch approved Shiga toxin-producing Escherichia coli (STEC) sampled and tested claim on beef trim. Such special labeling claims are voluntary. An establishment may use such claims when it demonstrates that they are truthful and not misleading (9 CFR 317.8(a)). FSIS must approve such claims before the establishment may use them on labels (9 CFR 412.1). The labeling guidance provided in this document applies to beef slaughter\fabrication establishments, although it\u2019s likely to be most useful to those that manufacture 50,000 pounds or more of trimmings daily and conduct lot by lot testing. II. Background On October 14, 2008, FSIS issued draft guidance entitled \u201cLabel Policy Guidance for N-60 Testing Claims for Boneless Beef Manufacturing Trimmings (\u201cTrim\u201d) Concerning E. coli O157:H7,\u201d and requested comments on the document. FSIS also held a public meeting to discuss the guidance and other topics concerning E. coli O157:H7. A second version of this document, published in May 2012, was revised in response to the comments on the draft guidance. The current version was updated to reflect the Agency\u2019s recent policy developments regarding non-O157 STEC. Since FSIS issued this compliance guideline for comments in May 2012, FSIS began testing beef manufacturing trimmings for six non-O157 STEC (O26, O45, O103, O111, O121, and O145) in addition to E. coli O157:H7. FSIS also declared these six non-O157 STEC adulterants in raw, non-intact beef products and product components."]}]

(<http://www.fsis.usda.gov/wps/wcm/connect/6aa26172-2d27-4534-99d48c528b285fd2/2010-0023.pdf?MOD=AJPERES>). Additionally, FSIS updated the Compliance Guideline for E. coli O157:H7 Sampled-and-Tested Claims for Boneless Beef Manufacturing Trim to recognize that establishments may want to submit a request for a labeling claim stating that product has been tested for the six additional STEC adulterants. FSIS clarified that it would need to see the same type of information to approve sampled and tested claims for the other adulterant STEC as it would need to see for sampled and tested claims concerning E. coli O157:H7. FSIS has developed the following guidance for establishments that wish to use a label claim asserting that beef trim has been sampled, tested, and found negative for E. coli O157:H7, adulterant non-O157 STEC or a general claim for all STEC. This label claim is intended to provide receiving establishments with information regarding the sampling and testing of beef trim for STEC organisms conducted by supplier establishments. FSIS may approve claims of this type if supported by adequate information.", "Compliance Guidelines for Shiga toxin Escherichia coli (STEC) Organisms Sampled and Tested Labeling Claims for Boneless Beef Manufacturing Trimmings (\u201cBeef Trim\u201d) 2 A label claim that beef trim comes from a production lot that has been sampled, tested, and found to be negative for STEC will be helpful for receiving establishments because Certificates of Analysis (COAs), which also provide sampling and testing information, frequently do not properly transfer with beef trim product through the distribution chain. This guidance document addresses label claims that are not intended to be displayed to consumers. FSIS may approve STEC sampled and tested claims on trim that goes to retail stores, for example to a retailer who purchases the trim for grinding. However, FSIS will not approve such a label claim for display to consumers because it may be misleading to consumers by suggesting that the end product is free of the pathogens or may not need to be cooked thoroughly. A negative test for STEC does not guarantee that all of the beef trim from the sampled production lot is free of the pathogens. Such assurance cannot be provided by sampling and testing. Rather, sampling and testing for STEC is intended to provide evidence regarding the effectiveness of Hazard Analysis and Critical Control Points (HACCP) measures related to the prevention, elimination, and reduction of the pathogens. A sampled and tested claim is meaningless \u2013 and therefore misleading \u2013 if the establishment asserting the claim has not incorporated into its HACCP system measures designed to control for STEC, and if the sampling and testing methodologies used are not designed to verify the effectiveness of those measures. Therefore, for FSIS to determine that a label claim that beef trim has been sampled, tested, and found negative for STEC is truthful and not misleading, the establishment requesting to make the claim would need to submit evidence demonstrating that its HACCP measures related to STEC are effective in reducing the pathogens to non-detectable levels, and that the results of the establishment\u2019s sampling and testing demonstrate that those HACCP measures are effective. To demonstrate that a labeling claim would be truthful and not misleading, FSIS would accept documentation showing that an establishment uses the FSIS sampling and testing methods or equivalent methods. The FSIS sampling method for beef trim is described in FSIS Directive 10,010.1. Additionally, relevant sampling program guidance, including a discussion of High Event Period criteria, is provided in the document \u201cCompliance Guideline for Establishments Sampling Beef Trimmings for Shiga Toxin-Producing Escherichia coli (STEC) Organisms or Virulence Markers.\u201d The method of analysis should be equivalent to that of the current method that the FSIS laboratories use as

cited in the Microbiological Laboratory Guidebook (MLG). A list of STEC testing methods that have been validated by recognized international organizations can be found at the following link: Foodborne Pathogen Test Kits Validated by Independent Organizations .","Compliance Guidelines for Shiga toxin Escherichia coli (STEC) Organisms Sampled and Tested Labeling Claims for Boneless Beef Manufacturing Trimmings (\u201cBeef Trim\u201d) 3 STEC testing methods that have not yet been validated by these organizations but have received FSIS Letters of No Objection can be found at the following link: STEC No Objection Letters While these sources of information indicate that the methodology has been validated for use in some context, it is important to confirm that the method of choice is fit for the intended purpose of the analysis and provides useful information for the food safety program used by the establishment. It is important for establishments to ensure that their private laboratory complies with the specific method that was validated, including the enrichment broth, incubation conditions, and test portion used to ensure that the pathogen screening test is effective. Private laboratories should have documented quality control programs that ensure the integrity of testing results. The establishment and laboratory should demonstrate confidence in test results and not re-sample or re-test pathogen-positive and non-compliant products. The sections below describe the types of information that FSIS would expect to see on labels that bear STEC sampled and tested claims to prevent the labels from being false or misleading. They also describe the specific types of documentation that interested persons would need to submit to FSIS to obtain sketch approval for the use of such claims. Labels that include such special claims need to be submitted in accordance with 9 CFR \u00a7 412.2 for evaluation and sketch approval by the Labeling and Program Delivery Staff (LPDS) before use. FSIS inspection program personnel (IPP) periodically will verify that the establishments that make such claims are performing the sampling and testing that are described in the supporting documentation. FSIS intends to provide instructions to IPP for verifying that product meets these claims in establishments that use such labeling claims. FSIS intends to issue these instructions before it approves such claims.

III. Information to Appear on a Label Bearing a Sampled and Tested Claim

A sampled and tested label claim should include all applicable features required by 9 CFR 317.2. FSIS likely would find that a sampled and tested claim for beef trim is not misleading if it is supported by the following information

1. A statement that the product in the labeled container is comprised of only beef trim derived from a production lot that has been sampled, tested and found negative for STEC;
2. A statement specifying that the sample collection method used was either the FSIS method or an equivalent method;
3. A statement specifying that the testing method used was either the FSIS method or an equivalent method;","Compliance Guidelines for Shiga toxin Escherichia coli (STEC) Organisms Sampled and Tested Labeling Claims for Boneless Beef Manufacturing Trimmings (\u201cBeef Trim\u201d) 4
4. A statement that sampling and testing was conducted independently from FSIS testing;
5. A statement identifying the production lot from which the sampled and tested trim was derived (e.g., lot identification number or lot code);
6. If the production lot identified by the sampled and tested claim was created by combining product from two or more source production lots of trim (for example to create a particular formulation of lean to fat content), a statement that (a) explains this fact; (b) explains whether all source lots of trim bear STEC sampled and tested labels; and (c) explains whether the lot of trim identified by the sampled and tested label was sampled and tested in its final formulation;
7. If the labeled product

(whether the label is applied to a container, a box, etc.) contains beef trim from a split lot (i.e., the labeled product contains only a portion of the production lot identified by the label or only a portion of any source production lot used to create the identified production lot), a statement that the labeled product contains part of a split lot; and 8. A statement of limited use indicating that the label may not be displayed at retail. The following are examples of labeling claims that would be deemed acceptable under various circumstances, provided the establishment submits adequate documentation to support the claim. Other wording also may be appropriate.

1. Beef trim from a production lot independently sampled and tested negative for E. Coli O157:H7 using FSIS sampling and testing methods. Production lot No. 12345. This label may not be displayed at retail.
2. Beef trim from a production lot independently sampled and tested negative for STEC using FSIS-equivalent sampling and testing methods. Derived from production lot No. 12345. Part of a split lot. This label may not be displayed at retail.
3. Beef trim from a production lot independently sampled and tested negative for STEC using FSIS sampling and testing methods. Production lot No. 12345. Contains product from multiple source lots. Source lots not labeled as sampled and tested. Lot No. 12345 was", "Compliance Guidelines for Shiga toxin Escherichia coli (STEC) Organisms Sampled and Tested Labeling Claims for Boneless Beef Manufacturing Trimmings (\u201cBeef Trim\u201d) 5 sampled and tested. This label may not be displayed at retail.
4. Beef trim from a production lot independently sampled and tested negative for STEC using FSIS sampling and testing methods. Production lot No. 12345. Contains product from multiple source lots. Source lots labeled as sampled and tested negative. Lot No. 12345 not sampled and tested negative. This label may not be displayed at retail.
5. Beef trim from a production lot independently sampled and tested negative for E. coli O157:H7 using FSIS sampling and testing methods. Derived from production lot No. 12345. Part of a split lot. Contains product from multiple source lots. Source lots and Lot No. 12345 sampled and tested negative. This label may not be displayed at retail.

IV. Documentation to be Included with the Label Submittal In order to ensure that a claim stating beef trim has been sampled, tested, and found negative for STEC is not misleading, an establishment should submit information that would allow FSIS to determine that the sampling results verify the effectiveness of the establishment\u2019s HACCP system in controlling the pathogen. The list that follows describes the types of documentation, all of which needs to be submitted to LPDS with the label application, which would enable FSIS to make this determination.

1. Documentation demonstrating that lots of beef trim used to produce the product labeled with a sampled and tested claim originated from carcasses slaughtered at an official establishment using at least one validated intervention for STEC at a Critical Control Point (CCP) in the slaughter establishment\u2019s HACCP plan;
2. Documentation demonstrating on-going communication (e.g. communication SOP, email records, phone logs) between establishments that use or commingle products that bear STEC sampled and tested claims and establishments that produced those products to ensure any changes to the HACCP plan are made known;
3. Documentation demonstrating that the sample collection method used is the same as or equivalent to the FSIS sample collection method described in FSIS Directive 10,010.1, and that the sampling is incorporated into the establishment\u2019s HACCP plan;" "Compliance Guidelines for Shiga toxin Escherichia coli (STEC) Organisms Sampled and Tested Labeling Claims for Boneless Beef Manufacturing Trimmings (\u201cBeef Trim\u201d) 6
4. Documentation demonstrating that the testing method used is the same as or equivalent to the

FSIS testing method described in the FSIS Microbiology Laboratory Guidebook, and that the testing is incorporated into the establishment's HACCP plan. This documentation should provide assurance that the testing method protocol has been appropriately validated, is fit for the intended purpose of the analysis, and provides useful information for the food safety program. The establishment also should maintain documentation that ensures that the private laboratory complies with the specific method protocol that was validated, including the enrichment broth, incubation conditions, and test portions used to ensure that the pathogen screening test is effective, and that the laboratory has a documented quality program that ensures the integrity of the testing result; 5. Documentation demonstrating that if any sample tests positive or presumptive positive for STEC, the production lot represented by that sample is diverted from raw ground beef operations (e.g., the positive production lots are diverted to cooking or other full lethality treatment that will destroy the pathogen) and demonstrating how the establishment will ensure that such production lots have received an appropriate disposition either at an official establishment, landfill operation, or renderer; Note: If product screens positive for STEC and is not confirmed to be negative, FSIS considers the product to be positive for the pathogen. 6. Documentation demonstrating that there is no re-sampling (collecting another sample) of any production lots that test positive or presumptive positive for STEC; 7. When either multiple operations within one establishment, or multiple establishments, are involved in creating the materials that will constitute a single production lot of sampled and tested trim, documentation that provides: a. An explanation of how and when all involved operations or establishments communicate information pertaining to sanitary dressing performance and trim testing results; b. An explanation of how that documentation will be made available to FSIS personnel for review at each establishment;" "Compliance Guidelines for Shiga toxin Escherichia coli (STEC) Organisms Sampled and Tested Labeling Claims for Boneless Beef Manufacturing Trimmings (\u201cBeef Trim\u201d) 7 c. An explanation of how the communicated information is used to investigate and adjust the HACCP system to ensure that the system is adequate to control STEC; and d. A discussion of how the combination of materials from separate operations or establishments may affect the microbiological independence of production lots; 8. Documentation demonstrating that the establishment maintains a written protocol describing the criteria used to distinguish an acceptable number of sporadic positives from a trend towards a systemic failure to control for STEC (i.e., high event period). These criteria should justify how the establishment discerns whether one production lot is microbiologically independent of another when the same source material is used to produce individual production lots. (Same source material is trim produced from one or more carcasses slaughtered and dressed consecutively or intermittently within a defined period of time (e.g., shift).) The protocol also should describe the decision-making criteria for product disposition when the establishment experiences a high event period; and 9. A description of how the establishment will use the FSIS approved sampled and tested label to identify the specific production lot tested (e.g., lot code or lot identification number). V. Procedures for Submitting Labels for Approval Establishments interested in utilizing an STEC sampled and tested labeling claim on their beef trim products need to submit label applications in accordance with the information provided on the FSIS Label Application Guidance web page. Questions about this guidance may be submitted to the Labeling and Program Delivery Staff (LPDS) through askFSIS or by telephone at 1-800-233-3935. When submitting a question, use

the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter STEC Labeling Claims Question Field: Enter question with as much detail as possible. Product Field: Select Labeling from the drop-down menu. Category Field: Select Labeling Regulations, Policies and Claims \u2013 Special Claims from the drop-down menu. Policy Arena: Select Domestic (U.S.) Only from the drop-down menu. 1 Additional guidance on designing high event period criteria is provided in the document \u201cCompliance Guideline for Establishments Sampling Beef Trimmings for Shiga Toxin-Producing Escherichia coli (STEC) Organisms or Virulence Markers.\u201d", "Compliance Guidelines for Shiga toxin Escherichia coli (STEC) Organisms Sampled and Tested Labeling Claims for Boneless Beef Manufacturing Trimmings (\u201cBeef Trim\u201d) 8 When all fields are complete, press Continue."}, {"file\_name": "FSIS\_GD\_2014\_0012", "title": "Pre-Harvest Management Controls and Intervention Options for Reducing Shiga Toxin-Producing Escherichia coli Shedding in Cattle: An Overview of Current Research", "num": "FSIS-GD-2014-0012", "id": "f98bfef5f372a97bfe9a511ebdd98c3608be2290e2843703ae83c9b8d8e33728", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/import/Reducing-Ecoli-Shedding-in-Cattle.pdf", "type": "pdf", "n\_pages": 32, "word\_count": 11213, "text\_by\_page": ["August 2014 This document provides an overview of the current status of pre-harvest control and intervention strategies discussed in scientific literature to reduce shedding of Shiga Toxin-Producing Escherichia coli in cattle. contaminated with STEC, Salmonella, and other pathogens. The meeting", "4 featured presentations on the latest research and included three break-out sessions to address the following questions: 1. What factors influence the shedding of Salmonella and E. coli O157:H7 and other STEC (e.g., age of cattle, stress conditions)? 2. What effective and practical mitigations are available to reduce the pathogen load in general, and Salmonella and STEC specifically, in cattle before slaughter? 3. How can producers, processors, and government work together to promote adoption of pre-harvest food safety mitigations? Meeting participants sought clarification of what super shedders are, and how they would be identified during production. They felt strongly that the United States should build upon successful mitigations used in foreign countries, allow the market to drive the value of any particular mitigation technology including vaccines, and streamline the regulatory approval process. They recommended also that there be sustained discussions among federal, industry, and academic partners to identify and put into practice pre-harvest mitigations for reducing foodborne hazards in beef. The meeting agenda, transcript, and participant\u2019s response to the questions can be found on the FSIS web site at:

<http://www.fsis.usda.gov/wps/portal/fsis/newsroom/meetings/past-meetings/past-meetings2011>. As discussed, this document provides innovative ways to control pathogens in beef at preharvest and pre-harvest pathogen control strategies for animals presented for slaughter. The application, state of the findings, and links to additional scientific references are provided for the strategies discussed. Food Safety Hazards Federally inspected establishments are required to conduct a hazard analysis as part of their Hazard Analysis and Critical Control Point (HACCP) system. The hazard analysis is required to include food safety hazards that can occur before, during, or after entry into the establishment (9 CFR 417.2). Fecal shedding in cattle is a hazard that occurs at pre-harvest and can continue in the holding pens at the establishment. This fecal shedding may result in contamination of the hides, and the contamination can subsequently be transferred to the carcass during carcass dressing. Establishments may address this hazard by incorporating purchase specifications, other programs, or agreements as part of their HACCP plans or prerequisite programs to require that their suppliers implement certain pre-harvest management controls. These programs, designed to support decisions in the hazard analysis, are part of the HACCP system. Pre-harvest Management Practices and Interventions FSIS recommends that slaughter establishments receive their cattle from beef producers that implement one or more documented pre-harvest management practices to reduce fecal shedding. FSIS encourages pre-harvest interventions as the first control steps in an integrated beef products safety system.", "5 This document describes several pre-harvest interventions and management practices and the state of the findings about these practices. Research on pre-harvest interventions for STEC is ongoing. Most of the research has focused on E. coli O157:H7 but has potential for reducing other strains of STEC. Therefore, this document focuses primarily on research conducted for E. coli O157:H7. Pre-harvest interventions that eliminate fecal shedding have yet to be discovered; however, current research suggests that at least two pre-harvest interventions, certain probiotics, and vaccines, have the potential to be effective in reducing fecal shedding in cattle. FSIS encourages slaughter establishments to share this information with their suppliers and consider its use in designing their food safety systems. FSIS will continue to monitor this type of research and update this document as needed. Veal FSIS test results show that the percent positive for STECs

from trimmings produced from veal appears to be higher than from trimmings produced from other cattle slaughter classes since the Agency began testing the six additional STECs in June 2012. In January 2013, FSIS consulted the National Advisory Committee on Meat and Poultry Inspection about the higher numbers seen in veal operations. The committee recommended that the Agency confer with ARS or other research providers to conduct research into pre-harvest risk factors associated with STEC in veal slaughter. The committee also recommended that the Agency promote research into the development of industry best management practices. The committee concluded with the following statement that is being considered by the Agency: Recognizing that pre-harvest practices can impact potential pathogen contamination, the Agency should conduct a series of stakeholder meetings to facilitate knowledge sharing and capturing to more fully fill the data gap that exists for this specific class of beef. The committee encourages the agency to investigate and develop recommendations for pre-harvest interventions and . . . ensure discussions with interested stakeholder meetings on this topic. Further, the committee recognizes potential differences between the subgroups bob veal and formula fed veal within the veal class and recommends the agency focus its efforts at the stakeholder meetings on this topic with intent to capture both optimum in-plant sanitary dressing procedures and pre-harvest best practices.

([http://www.fsis.usda.gov/wps/wcm/connect/1937a01a-7478-4d5d-9d4816b237f19a1e/NACMPI\\_Transcript\\_Subcmt1\\_011613.pdf?MOD=AJPERES](http://www.fsis.usda.gov/wps/wcm/connect/1937a01a-7478-4d5d-9d4816b237f19a1e/NACMPI_Transcript_Subcmt1_011613.pdf?MOD=AJPERES)) Background Information on STEC Shedding in Cattle E. coli O157:H7 is a food safety hazard well documented in scientific research. Appendix 1, \u201cWhat is Shiga toxin-producing E. coli?\u201d and Appendix 2 , \u201cEcological and Epidemiological Characteristics of E. coli O157:H7,\u201d provide general information regarding the pathogen. Appendix 3 is a quick reference table that summarizes the pre-harvest management options and interventions presented in this document." As suggested in some scientific literature, pre-harvest practices and interventions are grouped into three categories in this document: (1) exposure reduction strategies (environmental management), (2) exclusion strategies (treatments such as dietary and vaccination modifications), and (3) direct anti-pathogen strategies (certain types of treatments such as bacteriophages). Request for comments This document is a revision of a previous guidance document. As such, it is not subject to the Office of Management and Budget\u2019s (OMB) \u201cFinal Bulletin for Agency Good Guidance Practices\u201d (GGP). More information can be found on the FSIS web site:

However, FSIS is seeking comments on this document as part of its efforts to continuously assess and improve the effectiveness of policy documents. The comments will be considered for future revisions of this document. FSIS requests that all interested persons submit comments regarding any aspect of this document, including but not limited to: content, readability, applicability, and accessibility. Comments may be submitted by either of the following methods: (1) Online submission at regulations.gov: This web site provides the ability to type short comments directly into the comment field on this web page or attach a file for lengthier comments. Go to <http://www.regulations.gov> and follow the instructions for submitting comments. (2) Mail, including floppy disks or CD-ROMs, and hand- or courier-delivered items: Send to Docket Clerk, U.S. Department of Agriculture (USDA), FSIS, Patriots Plaza 3, 1400 Independence Avenue SW, Mailstop 3782, 8-163A, Washington, DC 20250-3700.

All items submitted by mail or electronic mail must include the Agency name, FSIS, and document title Pre-Harvest Management Controls and Intervention Options for Reducing Shiga Toxin-Producing Escherichia coli Shedding in Cattle: An Overview of Current Research, August 2014. Comments received in response to this document will be made available for public inspection and posted without change, including any personal information, to <http://www.regulations.gov>. Key Point: Sound management practices, including proper sanitation measures and pest control, can reduce levels of E. coli O157:H7 and other pathogens in the cattle\u2019s environment.","7 II. EXPOSURE REDUCTION STRATEGIES The goal of exposure reduction strategies is to reduce the frequency of exposure of cattle to contaminated sources in the environment, thereby reducing the prevalence of STEC in live animals. Pre-Harvest Cattle Management Controls Pre-harvest cattle management controls and interventions are emerging as an option that offers great opportunity to improve food safety. The beef industry is investigating production practices that reduce food safety risks. The beef industry has invested heavily in processing interventions to address E. coli O157:H7 in raw beef products. Despite these measures, E. coli O157:H7 remains a food safety hazard in our food supply. The following are the basic recommended principles of cattle management. 1. Clean water; 2. Clean feed; 3. Clean environment that is appropriately drained; 4. Separate housing of calves and heifers or reduced animal density; and 5. Biosecurity\u2014wildlife exclusion to the extent possible. FSIS supports the principles of good pre-harvest management control because they provide the foundation for the processing interventions and sanitary dressing procedures used to control E. coli O157:H7 contamination in raw beef. <http://digitalcommons.unl.edu/vetscidiss/10>. Management Practices and Transportation (1) Clean and Dry Bedding Clean and dry bedding may help prevent heavy soiling of the animal\u2019s brisket area. Keeping the brisket clean helps control contamination during

slaughter. The brisket area is the site that contacts hands and knives when the initial cut is made at the start of the hide removal process during sanitary dressing procedures. A clean brisket may help control hide contamination and transmission of E. coli O157:H7 within the herd. (2) Sanitation Practices on Farms and Feedlots The maintenance of clean clothes and equipment by farm and feedlot personnel can reduce the opportunities to transmit E. coli O157:H7 between herds or between cattle on the same farm or feed lot. However, it does not reduce E. coli O157:H7 shedding in cattle. Exclusion of animals other than livestock from access to cattle feed and water is a best practice. Insects, rodents, and other animals such as sheep and deer are known to be carriers of E. coli O157:H7. Pest management may reduce reservoirs of non-bovine sources of E. coli O157:H7 and reduce sources of contamination to water sources, feed, hides, and housing. (3) Housing Separate Housing of Calves and Heifers \u2013 Some research indicates that calves excrete E. coli O157:H7 more frequently and in greater numbers than adult animals. Separating calves from adults shows some effect in reducing prevalence and shedding of E. coli O157:H7 in calves. Housing calves away from other livestock may provide a mechanism to reduce E. coli O157:H7 in a dairy operation. However, separating calves is not practical in beef cow- Management Practices and Transportation (1) Clean and Dry Bedding (2) Sanitation Practices on Farms and Feedlots (3) Housing (4) Transportation", "9 calf operations. Off-site heifer raising is another option to reduce exposure of older cattle to the calves, but there may be biosecurity risks with bringing heifers back onto a farm. Animal Density \u2013 A recent study reported a significantly greater E. coli O157:H7 prevalence in feedlot cattle housed at high density of cattle per area compared to cattle housed at a low density of cattle per area. (4) Transportation Cross contamination among animals from different farms during transportation to the slaughter facility and at lairage (holding pens) can be an important source of hide contamination. Therefore, appropriate controls should be in place to minimize hide contamination. Recent research showed that loading areas and dust generated during loading can increase pathogen loads on the animals before and after shipping. Stress may play a role in the ability of E. coli O157:H7 to colonize the gastrointestinal tract and in E. coli O157:H7 fecal shedding. Stressful events, such as the stress associated with transportation, may be a factor in increased fecal shedding in cattle. However, one study suggested that the feedlot pen has a greater effect on hide contamination at the slaughter plant than transportation factors including temperaturehumidity index, loading density, and duration of transport. EXCLUSION REDUCTION STRATEGIES The goal of exclusion reduction strategies is to modify or change the microhabitat of the gastrointestinal tract of cattle so STEC will not be established or will be displaced by bacteria less harmful to humans. Cattle Water and Feed Management (1) Cattle Drinking Water Treatments Application: Research suggests that there is a correlation between cattle that drink contaminated water and *E. coli* O157:H7 shedding. Researchers are studying the application of chlorination, electrolyzed water, and ozonation as water treatments to improve and maintain drinking water quality. Chlorine is an FDA approved and commercially available water treatment used to disinfect cattle drinking water and to reduce the transmission of pathogens including *E. coli* O157:H7. Beef producers that use chlorine must maintain the required chlorine levels throughout the day in order to disinfect trough water effectively. Electrolyzed water and ozonation are also water treatment methods; however, specialized equipment is required to apply these interventions to drinking water sources. In addition, researchers have not tested electrolyzed water under field conditions. Findings: Adding chlorine to water at 2-5 PPM significantly reduces total *E. coli* concentrations. However, the effectiveness of the chlorine is diminished if organic material, such as manure, is present in the water. Under field conditions, treating livestock drinking water with chlorine has been shown to have a negligible effect on the prevalence of *E. coli* O157:H7. Chlorine water treatment may be more practical to implement than electrolyzed water and ozonation; however, its effect on *E. coli* O157:H7 shedding is inconclusive. (2) Cattle Feed Types and Feeding Strategies A. Feed Types Application: Research indicates that the type of feed, fasting, and feed additives can affect E. coli O157:H7 shedding in cattle. Researchers have studied the effects of feeding hay, grain, distillers grains, and forage on E. coli O157:H7 shedding in cattle. Findings: A significant amount of research has been conducted, but there is no conclusive evidence that feeding cattle forage is consistently effective at reducing pathogens under field conditions. Grains such as barley and distillers grains have been shown to increase E. coli O157:H7 shedding in cattle. Studies have shown that even the form of corn fed to cattle can affect E. coli O157:H7 shedding. Cattle fed steam-flaked corn shed more E. coli O157:H7 than those fed dry-rolled corn because of the passage of more starch to the hindgut where it is fermented to produce volatile fatty acids that kill E. coli O157:H7. Calves fed on grain-based diets shed more E. coli O157:H7 than those fed on a forage diet. While E. coli O157:H7 populations tend to be lower in cattle fed forage, pathogens are still found in cattle fed forage. Although some have claimed that grass-fed cattle have fewer pathogens than grain-fed cattle, researchers have found no significant food safety differences in grass-fed cattle versus corn-fed cattle. <http://link.springer.com/content/pdf/10.1007%2Fs00284-006-0200-9.pdf>. B. Feeding Strategies Application: Most US beef producers feed cattle a grain finishing diet. Abruptly feeding hay to cattle on a grain-based diet causes a shift in the available nutrients, thus selecting for organisms that displace *E. coli* O157:H7 and preventing colonization of the intestines by *E. coli* O157:H7. Some factors intrinsic to forage may explain some of the observations and inconsistencies found between forage and grainbased diets. Findings: Research suggests that feeding cattle hay in place of grain decreases the risk of food borne illness from *E. coli* O157:H7. A 2000 study showed that when cattle were switched to a hay diet, they had lower generic *E. coli* counts and total coliform counts than cattle fed a corn diet before slaughter. It has been suggested that the fiber component of hay may scrape the gut wall, physically removing the organism and contributing to reduced colonization and shedding. The research also shows that switching feedlot cattle from a high grain ration to hay during the last 5 days of finishing can result in a loss of an average of 2.2 lbs per head-per-day. Such a loss would have a negative impact on finishing cattle growth performance and carcass characteristics. An increase in *E. coli* O157:H7 shedding has been observed when cattle and sheep are fed poor quality forage or fasted. Other researchers have observed inconsistent shedding or an increase in *E. coli* O157:H7 shedding when the diet is switched from a high grain ration to a high quality hay or low quality forage. Impact of reducing the level of wet distillers grains fed to cattle before harvest on prevalence and levels of *Escherichia coli* O157:H7 in feces and on hides. *J. Food Prot.* 10:1611 \u2013 1617. C. Fasting Application: Fasting of cattle before and during transportation is a common pre-harvest management practice to reduce hide contamination during transport and during slaughter processing. Findings: Most research indicates that fasting may increase *E. coli* O157:H7 shedding. However, the reduction of ingesta present in the gastrointestinal tract before slaughter may be beneficial in decreasing fecal output, reducing the incidence of rumen spillage during carcass dressing, and thus reducing potential sources of carcass contamination. References: \u2022 Buchko, S.J., R.A. Holley, W.O. Olson, V.P.J. Gannon, D.M. Veira. 2000. The effect of fasting and diet on fecal shedding of *Escherichia coli* O157:H7 by cattle. *Can. J. Anim. Effect of duration of fasting and a short-term highroughage ration on the concentration of *Escherichia coli* biotype 1 in cattle feces. *J. Food Prot.* 61:531\u2013534. Water and Feed Additives (1) Seaweed Extract in Feed Application: Tasco-14 is an extract from the seaweed *Ascophyllum nodosum*, a known source of cytokinins with increased antioxidant activity. Currently, some beef producers feed the extract to cattle in commercial feedlots for various reasons, such as to improve carcass quality. Findings: Research indicates that Tasco-14 may be effective in reducing *E. coli* O157:H7 shedding in cattle. Several university studies demonstrated that supplementing cattle diets with Tasco-14 for two weeks before slaughter resulted in fewer naturally occurring *E. coli* O157:H7 in the feces and on the hides of cattle. References: Fasting cattle before and during transportation reduces hide contamination during transport and slaughter processing.", "17 \u2022 Bach, S.J., Y. Wang, T.A. McAllister. 2008. Miller. 2004. *Ascophyllum nodosum* supplementation: a preharvest intervention for reducing *Escherichia coli* O157:H7 and *Salmonella* spp. in feedlot steers. *J. Food Prot.* 67:1824 \u2013 1828. (2) Ractopamine Application: Ractopamine, a beta-agonist, is commercially available (OptaFlexx\u2122) as a feed additive. It is approved for use only in non-breeding cattle, specifically steers and heifers. The effect of ractopamine in the animal is to redirect nutrients that would have become fat and synthesize them into protein. The protein is used to increase muscle fiber size, which helps increase lean meat yield. A 2006 study showed that when feedlot cattle were fed ractopamine, the number of cattle shedding *E. coli* O157:H7 decreased. However, a 2011 study showed that ractopamine had no effect on fecal prevalence of *E. coli* O157:H7. In Russia, beta agonists cannot be used in beef. Findings: Preliminary studies indicated a decrease in *E. coli* O157:H7 shedding in cattle, but later studies indicated that ractopamine had minimal effect on fecal shedding of *E. coli* O157:H7. Reference:

[www.journalofanimalscience.org/content/89/9/2829.full.pdf](http://www.journalofanimalscience.org/content/89/9/2829.full.pdf). (3) Antibiotic Feed Additives Application: Antibiotics such as ionophores, neomycin sulfate, tetracycline, and oxytetracycline are used in cattle feed for various purposes. Antibiotics have been suggested as a means to reduce E. coli O157:H7 shedding in cattle. Ionophores are commercially available and routinely added to feed to increase feed efficiency in feedlot", "18 cattle. Some studies suggest that they may also reduce fecal shedding. Ionophores are not used in human medicine, so use of ionophores in cattle is not viewed as a concern with regard to development of antimicrobial resistant pathogens. Other antibiotics that are used in cattle feed for disease prevention, such as neomycin, oxytetracycline, and chlortetracycline, have uses in human medicine. Thus, their use in cattle to reduce E. coli O157:H7 shedding is controversial because of the risk associated with antimicrobial resistance and human health. Findings: Most of the research does not indicate that neomycin sulphate, tetracycline, and oxytetracycline are effective at reducing of E. coli O157:H7 shedding in cattle. Some researchers consider neomycin a good candidate for use as a pre-harvest E. coli O157:H7 management control in feedlot cattle. Some studies suggest that ionophores reduce E. coli O157:H7 shedding in certain circumstances. References: \u2022 Elder, R., J. Keen, T. Wittum, T.R. Callaway, T.S. Edrington, R.C. Anderson, J. Nisbet. 2002. Intervention to reduce fecal shedding of enterohemorrhagic Escherichia coli O157:H7 in naturally infected cattle using neomycin sulfate. *Am. Soc. Anim. Sci./Am. Dairy Sci. Assoc. (4) Probiotics Application: Probiotics preparations contain microorganisms or bacteria that are beneficial to the host animal. A variety of probiotic preparations are commercially available including *Lactobacillus acidophilus*. *Lactobacillus*-based direct-fed microbials are being used in feedlot finishing operations. Like antibiotics, a primary benefit of probiotics is to control intestinal infections in livestock. Beef producers must implement probiotics appropriately to avoid variable results. Findings: Supplementing cattle diets with certain strains of *Lactobacillus acidophilus* in *Lactobacillus*-based direct-fed microbials is demonstrated to be effective in reducing shedding of E. coli O157:H7 in feedlot cattle. Key Point: Research suggests that several probiotic preparations are effective in reducing

E. coli O157:H7 shedding in cattle. Studies show that probiotics administered under the right conditions and using the correct methods are effective feed supplements for farm animals." "19 However, not all strains of Lactobacillus acidophilus effectively reduce the shedding of E. coli O157:H7 when used in a Lactobacillus-based direct-fed microbial. References: \u2022

Karunasena, M.M. Brashears. 2007. Reduction of Escherichia coli O157 and Salmonella in feces and on hides of feedlot cattle using various doses of a direct-fed microbial. J. Food Prot. 70:2386-2391. \u2022 Younts-Dahl, S.M., G.D. Osborn, M.L. Galyean, J.D. Rivera, G.H. Loneragan, M.M. Brashears. 2005. Reduction of Escherichia coli O157 in finishing beef cattle by various doses of Lactobacillus acidophilus in direct-fed microbials. J. Food Prot. 68:6\ufe0f1310. (5) Colicin\ufe0f13producing E. coli strains Application: Colicins are antimicrobial proteins produced by certain strains of E. coli that can be effective in inhibiting the growth of E. coli O157:H7. Some strains can be effective in killing E. coli O157:H7 organisms. Use of colicin\ufe0f13producing E. coli strains, in feed or as direct fed products, may be effective in reducing fecal shedding of E. coli O157:H7. Findings: Several strains of E. coli can produce colicins that are inhibitory, in vitro, to diarrheagenic E. coli strains, including strains of serotype O157:H7 in cattle and that can significantly reduce numbers of E. coli O157:H7 in weaned calves but not in neonatal calves. One study found that a daily dose of 108 CFU of colicin E7-producing E. coli per gram of feed can significantly reduce the fecal shedding of E. coli O157:H7 in cattle or", "20 calves. Colicin E7\ufe0f13producing E. coli can also significantly reduce the overall colonization of O157:H7 in the gastrointestinal tracts of the steers. Research on the application of colicin\ufe0f13 producing E. coli strains as a pre-harvest intervention in cattle is ongoing. These products are not being used currently by producers, primarily because they are

expensive. References: \u2022 Bradley, D.E., S.P. Howard, H. Lior. 1991. IV. DIRECT ANTI-PATHOGEN STRATEGIES

The goal of direct anti-pathogen strategies is to target and kill the STEC.

(1) Cattle Hide Washing Application:

Hide washes are a very effective method to remove visible debris from hides as well as reducing the pathogen load on cattle hides in the live animal before slaughter or immediately after slaughter. It does not have any effect in reducing E. coli O157:H7 fecal shedding in cattle.

Findings:

A Beef Checkoff funded study of hide washing systems resulted in the development of Trichloromelamine \u2013 a non-toxic, biodegradable hide wash intervention that reduces foodborne pathogens on beef cattle hides by 50 percent.

Key Point:

Hide washes significantly reduce the bacterial load on cattle hides entering the plant for slaughter."

"In a study published in 2012, researchers at the United States Department of Agriculture\u2019s Agricultural Research Service (ARS), tested hypobromous acid (HOBr) as an antimicrobial treatment on hides at two concentrations, 220 and 500 ppm. At 220 ppm, HOBr reduced the prevalence of E. coli O157:H7 on hides from 25.3 to 10.1%. At 500 ppm, HOBr reduced the prevalence of E. coli O157:H7 on hides from 21.2 to 10.1%. Salmonella and aerobic plate counts, total coliform counts, and generic E. coli counts were also reduced. This study suggests that adoption of HOBr as a hide wash will reduce spoilage bacteria and pathogen prevalence, resulting in lower risk of carcass contamination.

Anim. Sci. 89(1):237-244. <http://www.journalofanimalscience.org/content/89/1/237.long>. \u2022 Terrance, M.A., D.M. Brichta-Harhay, J.M. Bosilevac, N. Kalchayanand, S.D. Shackelford, T.L. Wheeler, M. Koohmaraie. 2010. Super shedding of Escherichia coli O157:H7 by cattle and the impact on beef carcass contamination. J. Meat Sci. 86:32-37.

(2) Bacteriophages Applications: Bacteriophages are FDA approved for use in or on live cattle as a treatment or for control of E. coli O157:H7 shedding in cattle. Bacteriophages (phages) are viruses that kill bacteria. A subset of bacteriophages can reduce bacterial loads in and on cattle and on the carcasses post-harvest. In 2006, FSIS issued a no-objection letter for the use of bacteriophages on the hides of cattle in holding pens before slaughter to control E. coli O157:H7 and Salmonella. Beef slaughterers may also use them on hides of cattle before skinning. In February 2012, FSIS issued a no-objection letter for the use of an E. coli O157:H7 bacteriophage on the hides of cattle within lairage or holding pens, restraining areas, stunning areas, and stations immediately before hide removal. Shortly thereafter, in April 2012, FSIS issued a letter of no-objection for use of a STEC targeted bacteriophage cocktail that is effective for E. coli serogroups O157, O26, O45, O103, and O145 applied in the same manner as the one for E. coli O157:H7. "22 Killing pathogens on hides before removal is an effective way of reducing carcass contamination. Spraying or washing hides with bacteriophages is being used more widely at pre-harvest as more companies develop a marketing strategy for pre-harvest applications of their products. Finalyse\u00ae is a commercially available bacteriophage cocktail sprayed on cattle before their entering the establishment to reduce the load of E. coli. Findings:

A 2006 study suggests that the bacteriophage CEV1 shows promise as a component in a treatment for reduction of E. coli O157:H7 levels in food animals. Reducing E. coli O157:H7 in cattle by bacteriophage treatment is possible, but efforts to clear E. coli O157:H7 from cattle consistently with phage therapy may be unrealistic. The commercial application of this pre-harvest intervention to aid in the control of E. coli O157:H7 in cattle may be a few years in the future.

Microbiol. Biotechnol.* 64:270\u2013274. ", "23 (3) Competitive Exclusion Application: Researchers are developing ways to utilize competitive exclusion (CE) as a strategy to eliminate E. coli O157:H7 shedding in cattle. A pharmaceutical company recently received an investigational new animal drug (INAD) exemption from the Food and Drug Administration to use the product in cattle intended for use in human food. If beef producers use this product, there is a seven-day withdrawal time. Findings: In a 2003 study, researchers isolated and defined several E. coli strains including E. coli O157:H7 from cattle and found that certain cultures could displace an established E. coli O157 population in live cattle and reduce fecal shedding of E. coli strains in calves. Field trials have not yet been conducted. References: \u2022 Bradley, D.E., S.P. Howard, H. Lior. 1991. (4) Siderophore Receptor and Porin (SRP) Protein Vaccines Application: The USDA awarded conditional approval to Epitopix LLC for an E. coli bacterial extract vaccine using the SRP\u00ae Protein vaccine technology, for use to reduce E. coli O157:H7 shedding. A conditional license means a company can market the product, but that the USDA still requires additional safety and efficacy tests. EpitopixTM SRP protein-type vaccine targets the iron requirement of pathogenic gram-negative bacteria, such as E. coli O157:H7 and Salmonella, causing disruption of the bacteria\u2019s iron transport system, which ultimately causes death of the organism. The vaccine blocks the bacteria from absorbing iron and, without iron, the bacteria die. Competitive Exclusion Principle: When two species compete for the same critical resources within an environment, one of them will eventually outcompete and displace the other.", "24 Findings: Although the efficacy of vaccinating cattle for E. coli O157:H7 is still being questioned, and research is ongoing, a scientific study published in 2012 indicates that the SRP vaccine significantly reduces fecal prevalence of E. coli O157:H7 and prevalence of high shedders. SRP looks promising as an effective intervention for E. coli O157:H7 control in commercial feedlots. Researchers are currently studying the minimum amount of vaccine and

number of doses necessary to ensure maximum effectiveness in reducing E. coli O157:H7 in cattle when using SRP vaccines. The vaccine is commonly administered in three doses. Feedlot practices in the U.S. do not easily accommodate a three-dose vaccination treatment. The same 2012 study cited in the paragraph above indicates effectiveness of a two-dose regimen in reducing fecal prevalence of E. coli O157:H7 in high shedding cattle reared in a commercial feedlot in the summer on a finishing diet with 25% distiller's grains. Loneragan, J.T. Fox, D.T. Burkhardt, D.A. Emery, T.G. Nagaraja. 2009. Effects of a siderophore receptor and porin proteins-based vaccination on fecal shedding of Escherichia coli O157:H7 in experimentally inoculated cattle. J Food Prot. 2:866-869. (5) Bacterial Extract Vaccines Application: Econiche\u2122 is a bacterial extract vaccine. To make the vaccine, the bacteria are grown, and key proteins that cause the bacteria to attach to the intestines of cattle are extracted. Vaccinated cattle produce antibodies that affect the attachment proteins in the bacteria, preventing the bacteria from attaching and reproducing. Bioniche Life Sciences, Inc., of Belleville, Ontario, Canada, received full licensing approval for the use of Econiche\u2122 from the Canadian Food Inspection Agency in October 2008. In Pre-harvest Agreements Establishments are required to conduct a hazard analysis that includes food safety hazards that can occur before, during, or after entry into the establishment (9 CFR 417.2). Fecal shedding in cattle is a hazard that occurs at pre-harvest, before entry into the establishment. Establishments may address this hazard by incorporating purchase specifications or other programs or agreements as part of their HACCP plans or prerequisite programs to require that their suppliers implement certain pre-harvest management controls.", "25 December 2011, the Australian Quarantine and Inspection Service granted an import permit for the vaccine, a required first step in gaining full approval of the vaccine. In August 2012, the United Kingdom approved the importation of the vaccine to be used under conditions of a Special Treatment Certificate. Econiche\u2122 is not licensed in the United States. Econiche\u2122 is a three-dose vaccine, but it has also been tested as a two-dose vaccine. U.S. feedlot practices do not easily accommodate a three-dose vaccination treatment. Studies suggest that the efficacy of the vaccine is dose-dependent. Findings: Several published articles support the efficacy of Econiche\u2122. One study found that vaccinating feedlot cattle three times at three-week intervals against Type III secretory proteins of E. coli O157:H7 reduced the probability of fecal shedding of the E. coli O157:H7 by 59%. References: \u2022 Allen, K.J., 2011, R. Dragon, B.B. Finlay, A.A. Potter, D.J. Aper. 2011. guidance on production best practices (<http://www.bifasco.org/CMDocs/BIFSCO/Production%20Best%20Practices.pdf>) and cattle ecology and management options (<http://afabjournal.com/articles/current-and-near-marketintervention-strategies-for-reducing-shiga-toxin-producing-escherichia-coli-stec-shedding-in-cattle/>) produced in collaboration with ARS and academia. It is generally recognized that a multi-hurdle approach involving application of preventive measures at both pre-harvest and post-harvest should be more effective at reducing the chance of contamination at harvest. The Agency encourages pre-harvest interventions as the first control steps in an integrated food safety system. Multi-hurdle Approach Food producers recognize that applying pre-harvest interventions with post harvest technologies for a \u201cmulti-hurdle\u201d approach is the most effective way to minimize contamination of foods.

[http://www.ars.usda.gov/research/publications/publications.htm?seq\\_no\\_115=227290](http://www.ars.usda.gov/research/publications/publications.htm?seq_no_115=227290)," 27 FSIS acknowledges that several gaps exist in preharvest food safety research and knowledge. The Agency provides guidance and support to other government agencies that conduct research, academia, and industry to encourage them to conduct priority food safety research. FSIS research priorities are posted on FSIS\u2019 website at <http://www.fsis.usda.gov/wps/portal/fsis/topics/science/food-safety-research-priorities>. With appropriate data, further assessments and modeling of the relationships among fecal prevalence and concentration, hide contamination, and subsequent carcass contamination can be made to further define risks and benefits of STEC interventions on contamination of beef. \u201cThe purpose of the pre-harvest hurdle would simply be to control the prevalence to such a level that the in-plant hurdles would not be overwhelmed.\u201d Dr. Guy Loneragan, Texas Tech Professor, &The E. coli Issue", "28 Appendix 1: What are Shiga Toxin-Producing Escherichia coli (STEC)? STECs are associated with cattle and disease in humans. Escherichia coli (E. coli) bacteria live in the intestines of healthy cattle and have a symbiotic relationship with the cattle, an association where the E. coli derives benefit, and cattle are not harmed. Several strains of E. coli have evolved from being mildly pathogenic in humans to being highly pathogenic and capable of causing death when they infect humans. Symptoms of infection vary from person to person but often involve severe gastroenteritis, bloody diarrhea, vomiting, and mild fever if present. STEC can cause hemorrhagic colitis and hemolytic uremic syndrome in humans, especially in children, the elderly, and those in weakened immune states. Hemorrhagic colitis and hemolytic uremic syndrome are more commonly associated with infections resulting from E. coli O157:H7. Since 1994 when FSIS declared E. coli O157:H7 to be an adulterant in ground beef, it has been the E. coli strain of primary interest to FSIS because of its (1) presence on the hide and in the gut of cattle presented for slaughter; (2) its presence as a contaminant in raw beef component used to make ground beef; and (3) low infectious dose capable of causing severe human disease and death associated with consumption of undercooked non-intact beef products such as ground beef, which is the most frequently implicated source of E. coli O157:H7 outbreaks in the United States. However, the Centers for Disease Control and Prevention identified six additional strains of STEC (O26, O45, O103, O111, O121, and O145) that are pathogenic. These strains have been found on the hide, in the gut, and in the feces of cattle at levels comparable to those for E. coli O157:H7. In September 2011, FSIS declared these six additional strains as adulterants in beef. Since 1994, the beef industry has invested time, effort, and research on post-harvest interventions, focusing its efforts on

effective sanitary dressing practices (e.g., skinning and evisceration), treating beef carcasses with chemical or physical interventions during slaughter and dressing operations, and using sanitary practices during fabrication of trim and ground beef products to minimize cross contamination of ground beef product lots. These post-harvest in-plant efforts have reduced E. coli O157:H7 contamination on carcasses that may occur during carcass dressing. However, several studies have highlighted the importance of the E. coli O157:H7 load on feedlot cattle entering slaughter establishments as a critical factor for determining the level of E. coli O157:H7 contamination on dressed carcasses and eventually in ground beef. These studies suggest that if the E. coli O157:H7 \u2013 as well as non-O157 STEC \u2013 load on cattle entering the slaughter establishments is reduced, there would be a corresponding reduction in E. coli O157:H7 on carcasses and in ground beef. NOTE: In addition to STEC, cattle are reservoirs of several food borne pathogens including Campylobacter spp., Cryptosporidium spp., Listeria spp. and Salmonella and of several emerging human diseases, such as Helicobacterium pylori and Mycobacterium avium subspecies paratuberculosis.", "29 Appendix 2: Ecology and Epidemiology of E. coli O157:H7 Distribution: 1. The bacteria are found sporadically in the gut of individual animals but are not associated with clinical disease in animals; 2. Widespread in animals and commonly found in cattle; 3. High numbers of these bacteria are found in the colon and rectum of cattle 4. Survives in many different environments remaining viable in water, soil, and manure for several months; and 5. Can be found in a variety of species including humans. Prevalence (percentage of the population affected): 1. Higher during warm months; 2. Higher in calves than mature cattle; and 3. Higher prevalence in animals after gut bacteria have been affected by feed changes, antimicrobial dosing, or transportation stress.", "30 Appendix 3: Summary Table of Pre-harvest Management Controls and Intervention Options for Control of E. coli O157:H7 Shedding in Cattle A. Water and Feed Treatment Application 1. Water Treatments Chlorination at 2 \u2013 5 ppm is an effective and inexpensive means of reducing total E. coli counts in drinking water. The presence of organic matter reduces its effectiveness. It can be difficult to maintain adequate chlorine levels for it to be consistently effective. Electrolyzed water has been shown to be effective in killing E. coli O157:H7 under experimental conditions; it has not been tested under field conditions. Special equipment is required. Ozonation is an FDA approved process for disinfecting drinking water. Special equipment is required. 2. Feed Types and Feed Strategies Fasting of cattle before slaughter can reduce fecal output and reduce fecal soiling in the environment and on the hide. Some studies have shown an increase in E. coli O157:H7 shedding in fasting cattle. Grain vs. forage diets: In general, research supports that cattle on grain-based diets appear to shed higher levels of generic E. coli in their feces than cattle on forage diets but the effect of forage diets on fecal shedding of E. coli O157:H7 is inconclusive. Hay: Abrupt feeding of hay to cattle on a grain based diet can prevent colonization of E. coli O157:H7 in the intestines, but this may have detrimental effects on performance. Some studies have shown an increase in shedding in cattle fed poor quality forage. B. Water and Feed Additives Treatment Application 1. Antibiotics Some individual antibiotics have been shown to be effective in reducing fecal shedding of E. coli O157:H7 Development of antibiotic resistance to some antibiotics may have a negative impact on human health. Producer compliance with withdrawal times is required to prevent antibiotic residues in", "31 cattle presented for slaughter. 2. Probiotics Research supports the efficacy of some combinations of probiotic bacteria strains. There is no systemic absorption and no concerns of drug residues

with their use. They must be administered correctly to be effective. 3. Colicin-producing E. coli strains Use of colicin-producing E. coli strains, in feed or as direct fed products may be effective in reducing fecal shedding of E. coli O157:H7. However, colicins are not easily produced and are expensive. 4. Seaweed Extract (Tasco \u2013 14) When used as a feed supplement for two weeks before slaughter, it results in fewer naturally occurring E. coli O157:H7 in the feces and on the hides of cattle. However, some researchers indicate that data are insufficient to recommend that it can be used alone to control STEC. 5. Ractopamine Preliminary studies have demonstrated a decrease in fecal shedding of E. coli O157:H7 and Salmonella in cattle. This is an FDA approved feed supplement for use to improve cattle quality and performance. Currently not FDA approved for reducing fecal shedding. C. Live Animal Treatments Treatment

Application 1. Bacteriophage Bacteriophages are FDA approved for use in or on live cattle as a treatment or for control of E. coli O157:H7 shedding in cattle. As recently as April 2012, FSIS issued a letter of no objection for use of a Shiga toxinproducing E. coli targeted bacteriophage cocktail effective for E. coli serogroups O157, 026, 045, 0103, and 0145 for use on the hides of cattle within lairage or holding pens, restraining areas, stunning areas, and stations immediately before hide removal. 2. Competitive Exclusion (CE) Can be an effective means to interfere with the ability of E. coli O157:H7 to adhere to the intestinal lining and populate the gut. Several products are under research and development. 3. Vaccines Studies of two types of vaccines have demonstrated that vaccines can be effective in reducing colonization and adherence of E. coli O157:H7 in the intestinal tract and", "32 reduce fecal shedding in vaccinated cattle. The efficacy and safety of the vaccines are still being validated. D.

Management Practices and Transportation Treatment Application 1. Clean and Dry Bedding May help prevent heavy soiling of the brisket area of cattle, decreasing the potential for contamination during carcass dressing. Inconclusive evidence as to whether it reduces transmission of E. coli O157:H7 within the herd. 2. Sanitation Practices on Farms and Feedlots Maintaining good hygiene practices among farm and feedlot workers and sanitation of equipment and premises may prevent cross contamination between and within cattle herds. 3. Pest Management Control of insect, bird, rodent and other pest populations may reduce reservoirs of nonbovine sources of E. coli O157:H7 and reduce sources of contamination to water, feed, housing, and hides. 4. Maintain Closed Herds Maintaining cattle in closed herds reduces social stress and eliminates cross contamination between herds. Reducing stress may help to reduce fecal shedding of E. coli O157:H7. 5. Transportation Cross contamination between animals from different farms or feedlots during transportation to the slaughter plant and at lairage can be an important source of hide contamination. Stress of handling and transportation may affect fecal shedding of E. coli O157:H7 in individual cattle."]}, {"file\_name": "FSIS\_GD\_2014\_0013", "title": "Compliance Guideline for Training Establishment Carcass Sorters in the New Poultry Inspection System (NPIS)", "num": "FSIS-GD-2014-

..... 42 I. PURPOSE This compliance guideline would help poultry slaughter establishments train their employees to conduct the carcass and associated viscera sorting activities that are required under the New Poultry Inspection System (NPIS). II. BACKGROUND The Food Safety and Inspection Service (FSIS) published a final rule <a href="http://www.fsis.usda.gov/wps/wcm/connect/00ffa106-f373-437a-9cf36417f289bfc2/2011-0012F.pdf?MOD=AJPERES">http://www.fsis.usda.gov/wps/wcm/connect/00ffa106-f373-437a-9cf36417f289bfc2/2011-0012F.pdf?MOD=AJPERES</a> ; to establish a new inspection system called the NPIS. Under the NPIS establishment personnel are required to sort carcasses and remove unacceptable carcasses and parts before the birds are presented to the FSIS online carcass inspector. FSIS believes that training of establishment sorters is vitally important to ensure that they are able to properly perform their duties under the NPIS. Therefore, FSIS has developed guidance documents to assist establishments in the training of their carcass sorters. This guidance is based on the training that FSIS provides to its online inspection personnel, who are responsible for sorting carcasses under the existing inspection systems. The Agency is	

posting this guidance material on the FSIS Web site:

<http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatory-compliance/complianceguides-index>

and announcing the availability of such materials through the FSIS Constituent Update. This Compliance Guideline articulates how establishments can meet FSIS expectations regarding sorting activities under the NPIS. It is important to note that this Guidance represents FSIS\u2019s current thinking on this topic and should be considered useable as of this issuance. Request for Comments: FSIS is seeking comments on this guidance document. All interested persons may submit comments regarding any aspect of this document, including but not limited to: content, readability, applicability, and accessibility. FSIS will update these guidelines in response to any comments that it receives and as needed to reflect the most current information available to FSIS and stakeholders. The comment period will be 60 days. Comments may be submitted by either of the following methods:

Federal eRulemaking Portal: This Web site provides the ability to type short comments directly into the comment field on this Web page or attach a file for lengthier comments. Go to <http://www.regulations.gov> and follow the online instructions at that site for submitting comments. Mail, including CD-ROMs, and hand- or courier-delivered items: Send to Docket Clerk, U.S. Department of Agriculture, Food Safety and Inspection Service, Patriots Plaza 3, 1400 Independence Avenue, SW, Mailstop 3782, Room 8-163A, Washington, DC 20250-3700.","4

Instructions: All items submitted by mail or electronic mail must include the Agency name, FSIS,

and document title: FSIS Compliance Guideline for Training Establishment Carcass Sorters in the New Poultry Inspection System (NPIS). Comments received will be made available for public inspection and posted without change, including any personal information, to

<http://www.regulations.gov> . III. GUIDANCE FOR SORTER TRAINING PROGRAMS A. Training Program Elements This compliance guideline recommends training elements and post-mortem inspection standards that FSIS has found effective in training FSIS online inspectors to identify carcasses and parts exhibiting condemnable conditions that are unwholesome and unfit for human food. Poultry slaughter establishments can use the information in this guideline to train establishment employees that would conduct sorting activities under the NPIS. As stated previously this compliance guideline is based on FSIS training materials for its online inspectors which are available at:

<http://www.fsis.usda.gov/wps/portal/fsis/topics/inspection/workforce-training/regional-onsite-training>; These training materials can be a valuable resource for additional details and background, such as providing a module for familiarizing employees with the steps in the slaughter process. Training objectives, workshops and evaluation tests are also provided in the training. Proper training is important to establishment sorters\u2019 ability to make accurate decisions on how to address carcasses exhibiting condemnable conditions.

Under the NPIS, if sorters do not make these decisions correctly, FSIS inspection personnel are required to take actions such as stopping the production line to remove contaminated carcasses, issuing non-compliance records, and directing the establishment to reduce the line speed to ensure that the establishment is able to maintain process control, and that the online carcass inspector is able to conduct a carcass by carcass inspection. A single training method or program may not be applicable to all establishments. Individual establishments should design training programs consistent with the operational conditions in the establishment. FSIS recommends that each establishment develop a standardized training program for its sorters to

enable them to properly identify and dispose of carcasses and parts exhibiting condemnable conditions to ensure that carcasses and parts are not used as human food. FSIS recommends the following types of training as effective elements of a sorter training program:

- \u2022 Classroom or offline training is a lecture type presentation that provides essential information for sorters to be able to:
  - o recognize and name common parts of poultry carcasses and organs;
  - o recognize and name common conditions affecting poultry carcasses and viscera;
  - o differentiate among normal, localized, and generalized conditions affecting poultry carcasses and viscera;
  - o determine the disposition of each carcass and viscera and take appropriate actions to ensure removal and disposal of unwholesome and unfit carcasses, parts, or viscera to ensure they can not be used as human food; and
  - o take appropriate recording actions.
- NOTE: An exam or self-assessment for trainees may be helpful to measure and quantify understanding and comprehension of training.
- \u2022 Wet lab is an offline training activity that provides trainees with practical application of what they have learned in classroom training. Features include:
  - o using real examples of carcasses and parts both normal and abnormal;
  - o performing hands on practice prior to beginning normal duties online to identify carcass conditions and make dispositions;
  - o acting on carcass disposition made; and
  - o recording actions.
- \u2022 On the job training is to practice what has been learned in lecture including:
  - o performing sorting at production rates;
  - o identifying carcass, parts, and viscera dispositions;
  - o receiving real time feedback from supervisors; and
  - o taking appropriate actions as determined necessary.
- \u2022 Follow up sessions (called correlations) are to reinforce previous learning. Features include:
  - o conducting these sessions at a set regular frequency,
  - o discussing regularly standardized procedures to make decisions to identify and properly dispose of carcasses on a continuous basis at production rates; and
  - o describing reasons for making dispositions and appropriate actions.
- \u2022 Continuous monitoring of individual employee performance to maintain skill level If questions related to dispositions arise establishment management may contact the FSIS public health veterinarian (PHV) or send questions to askFSIS. (<http://askfsis.custhelp.com/>);

"6 B. Carcass Disposition and Sorting Procedures

The purpose of carcass sorting is to separate carcasses, parts and viscera that are unwholesome and unfit for human food from those that are fit for human food. When carcasses and parts exhibiting condemnable conditions are identified, they would be properly disposed to ensure they are not used as human food. Through observation and occasional touching of the carcass and viscera, sorters make decisions called dispositions of each carcass, part, or viscera. Dispositions are based on the stage of the disease and to what degree, if any, the bird is recovering from the disease at the time the bird is slaughtered. If a disease process or injury exists in the live bird, the disease will stop progressing at the time of slaughter, but the visible changes (lesions) in the bird caused by the illness or injury will remain. The more severely affected a bird is, the more likely the whole carcass is unwholesome. Under the NPIS, the establishment sorter would make a decision about the wholesomeness and fitness of each carcass and viscera and properly dispose of unwholesome carcasses, parts and viscera to ensure they are not used as human food.

- \u2022 If the carcass and viscera appear wholesome, they would be allowed to continue down the line to the FSIS carcass inspector located at the end of the line.
- \u2022 If the carcass is wholesome except for localized conditions that can be removed, those portions of the carcass exhibiting condemnable conditions would be removed and disposed of properly. The rest of the carcass is wholesome and would proceed down line to

the FSIS online carcass inspector. \u2022 Localized conditions means one or more conditions exist in the carcass or viscera, but each condition affects only one particular part and does not relate to the other parts of the carcass or viscera. The localized portions of carcasses, parts, and viscera are unwholesome and unfit and actions may be taken to trim, salvage or reprocess locally affected carcasses either on the line or off the line. The affected tissues that are unwholesome would be removed and disposed of properly as described above. \u2022 Generalized conditions include conditions that have affected the carcass to the extent that much of the carcass is affected and cannot be trimmed or salvaged. Carcasses and viscera affected with generalized disease conditions are unwholesome and unfit for human food and should be disposed of properly. (In some cases, the viscera may be saved for human food.) \u2022 Generalized conditions also include those conditions that make the entire carcass and viscera unwholesome, and the carcass and viscera must be properly disposed to ensure that they are not used as human food. \u2022 Finally, generalized conditions also include disease conditions that produce systemic change in birds. Those carcasses and viscera show certain obvious changes (see section V. A. Septicemia and Toxemia) that affect the whole", "7 carcass. Carcasses showing systemic change may also exhibit a localized condition. In either case any carcasses showing systemic change would require proper disposal of the entire carcass and viscera to ensure they are not used as human food. \u2022 If the carcasses exhibit conditions that are questionable and require further review, then the carcasses could be placed on a holding rack for further review by establishment supervisors or team leaders. This compliance guideline includes an appendix to be used as resources to assist establishments in the training of sorters. Appendix: Anatomy of Poultry is provided for establishment sorters to recognize common parts of the poultry carcass, skeleton, and digestive tract. Image Descriptions are provided in the text of this guide to describe the conditions of carcasses and parts shown in each image. The descriptions are under each image and a list of the descriptions is also located at the end of this document. FSIS has found that using standardized procedures and thought processes result in effective and accurate sorting on a continuous basis. A single sorting procedure or thought process may not be applicable to all establishments. FSIS recommends that sorters on a moving line use standardized procedures to enable them to make accurate dispositions on a continuous basis.

IV. NORMAL CARCASSES, PARTS, AND VISCERA

A. General Features

Knowing how normal carcasses, parts, and viscera appear is necessary to accurately identify carcasses, parts, or viscera that are abnormal. Diseases and other abnormalities produce visible changes to poultry carcasses. Poultry carcasses that are normal can look different from each other because of their age, breed, diet and the slaughter practices of the establishment. Normal young chickens and turkeys will have healthy skin, firm muscles, and fat in the flaps, the gizzard and around the heart. There may be some slight color changes to the skin of the drumstick and thigh and sometimes in the fat inside their bodies. The best way to learn what is normal is to look at birds under the direction of establishment supervisors or lead team members. Normal carcasses, parts, and viscera are not affected with disease or other conditions. If the carcass is wholesome and normal without any localized or generalized disease or other conditions, it would be allowed to continue down the line to the FSIS online carcass inspector. The following images show normal carcasses.", "8 10-1822 This is a well-nourished young chicken with ample body fat and no obvious blemishes. The body is plump. The general form of the wings and hips is round. The skin appears uniform in color, moist, and thick. The

underlying muscle tissue is barely visible through the skin. 07-0877 This is a well-nourished young chicken with ample body fat and minimal blemishes. The body is plump. The general form of the wings and hips is round. The skin appears uniform in color, moist, and thick. The underlying muscle tissue is barely visible through the skin. The yellow color is due to yellow plant pigments in the feed. 10-1846 This is an adequately nourished young chicken with adequate body fat and minimal blemishes. The body is slender. The general form of the wings and sternum is angular. The skin appears uniform in color, moist, and thin. The underlying muscle tissue is visible through the skin. 10-1320 This is a well-nourished young turkey with ample body fat and minimal blemishes. The body is plump. The general form of 10-1324 This is a well-nourished young turkey with ample body fat and minimal blemishes. The body is plump. The general form 10-1318 This is an adequately nourished young turkey with adequate body fat and minimal blemishes. The body is slender. The general form ", "9 the wings and hips is round. The skin appears uniform in color, moist, and thick. The underlying muscle tissue is barely visible through the skin. of the wings and hips is round. The skin appears uniform in color, moist, and thick. The underlying muscle tissue is barely visible through the skin. of the wings and sternum is angular. The skin appears uniform in color, moist, and thin. The underlying muscle tissue is visible through the skin. B. Normal Skin 06-0316 The skin of this young chicken appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The minor quality defects \u2013 feather remnant and scratches \u2013 do not make the skin unsafe or unfit for human food. 10-0403 The skin of this young chicken appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The minor quality defects \u2013 feather remnants and red blemishes \u2013 do not make the skin unsafe or unfit for human food. 10-1161 The skin of this young chicken appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The minor quality defects \u2013 red blemishes \u2013 do not make the skin unsafe or unfit for human food.", "10 10-1465 This is a well-nourished young chicken with ample body fat and no obvious blemishes. The skin appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. 10-1532 The skin of this young turkey appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The minor quality defects \u2013 surface blemishes \u2013 do not make the skin unsafe or unfit for human food. 10-1606 The skin of this young turkey appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The minor quality defects \u2013 retained cuticle and feather remnant \u2013 do not make the skin unsafe or unfit for human food. C. Normal air sacs 10-2223 The normal thoracic and abdominal air sacs in this young turkey appear thin, pliable, and somewhat 10-1044 The normal thoracic air sac in this young chicken appears thin, pliable, and somewhat transparent. 10-1046 The normal thoracic air sac in this young chicken appears thin, pliable, and somewhat transparent.", "11 transparent. The minor quality defect \u2013 lung \u2013 does not make the carcass unsafe or unfit for human food. D. Normal Liver 10-1807 This normal liver in a young chicken appears reddishpurple with lights spots and blotches. The general outline is a smooth, unbroken curve. The texture of a normal liver is firm. The normal fat attached to the gizzard

appears uniformly white and completely opaque. 06-0228 This normal liver in a young turkey appears brown with light spots and blotches. The general outline is a smooth, unbroken curve. The texture of a normal liver is firm. 09-0690 These normal livers from two young turkeys appear reddish-brown with lights spots and blotches. The general outline is a smooth, unbroken curve. The dry appearance of the liver on the left is a post mortem artifact. The texture of a normal liver is firm. E. Normal Heart", "12 07-0159 This normal heart in a young chicken appears reddish-tan with uniformly white fat where the arteries and veins attach. The surface color appears uniform. The general outline is a smooth, unbroken curve except where the arteries and veins attach. 03-0732 This normal heart in a young turkey appears red with uniformly white fat where the arteries and veins attach. The surface exhibits spots and blotches. The general outline is a smooth, unbroken curve except where the arteries and veins attach. 09-0691 These two normal hearts from two young turkeys appear red with uniformly white fat where the arteries and veins attach. The surface exhibits spots and blotches. The general outline is a smooth, unbroken curve except where the arteries and veins attach. F. Normal Spleen 07-0242 These normal spleens from young chickens are round to oval. Their color varies from red to tan. The surface color appears uniform or exhibits spots and blotches. 09-0693 These normal spleens from young turkeys are round to oval. Their color varies from red to tan. The surface color appears uniform or exhibits spots and blotches.", "13 G. Normal Joints, Tendons, and Bone Marrow 10-1232 This normal joint surface and tendon in a young turkey are white. The surface is shiny. 10-0236 This normal joint surface and tendon in a young chicken are white. The surface is shiny. 09-0794 This normal bone marrow from a young turkey appears uniformly red with a fine texture. V. GENERALIZED CONDITIONS REQUIRING WHOLE BIRD DISPOSAL A.

Septicemia\Toxemia Septicemia\toxemia (Sep\Tox) is caused by disease-producing bacteria and their toxins in the blood which produce systemic change in the bird. Systemic change affects the body as a whole, rather than localized portions of it. The systemic changes found in Sep\Tox are the result of the bird\u2019s organ systems not working properly. Cells weaken allowing blood to leak out of vessels (hemorrhage) into the viscera organs (liver, spleen, kidneys) and muscles of the bird. Other changes cause drying out (dehydration) of the skin and muscle wasting. Sep\Tox carcasses are usually dark in color with dark reddish viscera, especially the gizzard and heart fat. Other fat may also have an abnormal color ranging from pale to brownish red. The kidneys, liver, and spleen may appear swollen. Inside the cavity of the carcass small amounts of fluid mixed with blood may be found. In both eviscerated (opened to remove the guts) and non-eviscerated carcasses, the skin and muscle will appear dark or blue and have a dried appearance (dehydrated). The carcasses may also show muscle breakdown or wasting which gives a shrunken appearance especially to the breast muscles. The keel bone may be seen sticking out from beneath the skin of the breast muscles. If a carcass shows systemic change (Sep\Tox), as described above, it is unwholesome and must be disposed of properly to ensure the carcass and its viscera are not used as human food. However, not every carcass affected with Sep\Tox will show all of these signs.", "14 If carcasses are affected with any other condition or disease and also shows signs of systemic change (Sep\tox), the carcass and its viscera must be disposed of properly to ensure they are not used as human food. What to Look For: \u2022 carcass appears dark red, pale, or blue in color; \u2022 severe drying out of the skin and muscle may be observed; \u2022 liver, kidneys, and spleen are swollen and congested (filled up) with blood; \u2022 carcass has generalized muscle wasting. Do not

dispose of carcasses if: \u2022 only dark skin or meat is observed, and the rest of the carcass is normal; \u2022 the birds are only small birds and have good fat color and healthy looking skin and meat (flesh); and \u2022 the carcass appears only slightly dehydrated (the skin looks a little dry). 10-1901 This young chicken evidences adequate body fat and normal skin. The uniformly dark muscle tissue is suggestive of an extreme loss of body fluids, which is consistent with a generalized disease condition. 04-0536 This young chicken evidences necrosis and hemorrhage in the liver and spleen. The liver appears reddish-brown. The general outline is a smooth, unbroken curve. The linear white areas are soft and suggestive of dead tissue. The dark red areas in the liver and dark purple spleen are characteristic of hemorrhage. The parallel orientation of the white and dark red tissue in the liver is 07-0564 This young chicken evidences hemorrhage in the heart. The general outline is a smooth, unbroken curve except where the arteries and veins attach. The dark red surface blotches are characteristic with hemorrhage, which is consistent with a generalized disease condition.", "15 suggestive of swelling caused by the liver pressing against the ribs. Necrosis and hemorrhage are consistent with a generalized disease condition. 10-2017 This young chicken evidences necrosis in the liver. The liver appears red. A significant portion of the liver is pink. Exudates are visible on the surface. The general outline is a smooth, unbroken curve. Necrosis with exudates is consistent with a generalized disease condition. The yellow color of the fat is due to yellow plant pigments in the feed. 09-0625 This young turkey evidences necrosis in the liver. The liver appears red. The general outline is a smooth, unbroken curve. The linear white areas are soft and suggestive of dead tissue. The parallel orientation of the white tissue is suggestive of swelling caused by the liver pressing against the ribs. Necrosis is consistent with a generalized disease condition. 09-0921 This young chicken evidences necrosis in the liver and hemorrhage in the spleen. The liver is soft with white blotches suggestive of dead tissue. The general outline is a smooth, unbroken curve. The dark purple and soft spleen is characteristic of hemorrhage. The heart appears normal. Necrosis and hemorrhage are consistent with a generalized disease condition.", "16 07-0851 This young chicken evidences adequate body fat and normal skin. The enlarged joint at the end of the drumstick is suggestive of inflammation. The uniformly dark muscle tissue is suggestive of extreme loss of body fluids. Inflammation with loss of body fluids are compatible with wasting, which is a generalized disease condition. 10-1950 This young chicken evidences inadequate body fat and normal skin. The prominent keel bone and uniformly dark muscle tissue are compatible with wasting, which is consistent with a generalized disease condition. 10-1257 This young turkey evidences inadequate body fat and normal skin. The prominent thighbone and uniformly dark muscle tissue are compatible with wasting, which is consistent with a generalized disease condition. 10-1352 This young turkey evidences inadequate body fat and normal skin. The linear, red blemishes in the skin are veins filled with blood. The prominent thighbone and uniformly dark muscle tissue 10-0866 The fat attached to the gizzard of this young turkey appears thin, pink, and transparent. This is compatible with wasting, which is a generalized disease 10-0706 The heart of this young turkey appears wet, and offwhite. The fat, normally visible where the arteries and veins attach, is gone. The general outline is no longer a smooth, unbroken curve.", "17 are compatible with wasting, which is consistent with a generalized disease condition. condition. This is compatible with wasting, which is a generalized disease condition. B. Cadaver A cadaver is a generalized condition that causes the carcass and viscera to be unwholesome and unfit for human food. Cadavers are any birds that did not bleed

out properly due to a poor or missed cut of the neck veins before the bird entered the scalding tank. The heat of the scalding tank causes blood left in the carcass to expand into the skin blood vessels, giving the skin of the carcass and neck a cherry red to purple color. The blood also accumulates in the dependent (lower) regions, such as the necks, wings, and upper breast area. Some cadavers may appear red all over; others will appear red only in the lower regions of the carcass. The blood vessels in the viscera will appear enlarged and the liver may appear burgundy colored. The entire carcass and viscera of cadavers are unwholesome and must be disposed of properly to ensure that they are not used as human food. What to Look For: \u2022 cherry red to purple color of whole carcass or the lower regions of the carcass; \u2022 sometimes, just the neck will appear cherry red or purple color; \u2022 may be no cut on the neck, or may be only partially cut; and \u2022 blood vessels in the viscera may appear engorged (filled up with blood). NOTE: Free blood found in the body cavity and on the viscera (not inside the blood vessels) may be caused by improper stunning. Those carcasses are not cadavers. A thorough examination of the carcass may be necessary to make this determination.

05-0899 These are two adequately fleshed young chickens with ample body fat, normal skin, and minimal blemishes. The carcass on the right has normal skin color. The skin over the breast, thigh, and drumstick on the carcass on the left is dark red. The red skin discoloration of the otherwise normal carcass is consistent with a bird that was still breathing when it entered the scald tank. fleshed young turkey with ample body fat and normal skin. The skin over the entire carcass is dark red. The red skin discoloration of the otherwise normal carcass is consistent with a bird that was still breathing when it entered the scald tank. this young chicken is dark red. A visible cut across the cervical vessels is absent. The red skin discoloration and absence of a cervical cut are consistent with a cadaver - a bird that was still breathing when it entered the scald tank. Cadavers are unfit for human food. C. Dead on Arrival (DOA) DOAs are birds that have died by means other than slaughter and are not allowed to be brought into the establishment. However, if DOAs are mistakenly hung on the line, they are to be removed as quickly as possible from the slaughter or evisceration line. Dead on arrival carcasses will have red to purple color and will be cool or cold to the touch. Also, the bird may have a floppy neck. The carcasses may also feel stiff and may have a foul (bad smelling) odor. DOAs are unwholesome and to be disposed of properly to ensure they are not used as human food. What to Look For: \u2022 red to purple color; \u2022 cool or cold to the touch; \u2022 may have a floppy neck; \u2022 feel stiff; or \u2022 may smell bad.

06-0298 This is an adequately fleshed", "19 young chicken with ample body fat, normal skin, and minimal blemishes. The overall dark appearance evidences dehydration. The prominent dark red discoloration of one side of the carcass is suggestive of blood setting in the carcass. Depending on the ambient temperature and time since death, the carcass might be cool and\or stiff. The overall condition is consistent with a bird that was dead on arrival. D. Leukosis

Leukosis is a tumor-causing (neoplastic) viral infection of young chickens. The tumors are seldom seen now because of the vaccination of all birds. The tumors are often small, round, well-defined white to tan nodules in the liver, spleen, or kidney. In the liver or other organs the tumors may appear as white specks. When the skin is affected, the tumors appear in the feather follicle as bumps that are round, small, and whitish to light yellow in color. Leukosis can appear in just the viscera or just in the skin of the carcass; but any carcass affected with only one (or more) of the leukosis tumors in the skin or the viscera are unwholesome; both the

carcass and its viscera must be disposed of properly to ensure they are not used as human food. What to Look For: \u2022 One or more tumors in the visceral organs or the skin. \u2022 Tumors appear white to tan, small, round, and well-defined. \u2022 Carcasses with one or more of these tumors are unwholesome, and the entire carcass and viscera must be disposed of properly as described above.", "20 09-0910 This young chicken has round, white nodules, with smooth borders, throughout the liver and spleen. The heart appears normal. Such nodules are compatible with the avian leukosis complex, which is a generalized tumor condition requiring disposal of carcass and viscera. 09-0904 This young chicken has round, white nodules, with smooth borders, throughout the liver and spleen. The heart appears normal. Such nodules are compatible with the avian leukosis complex, which is a generalized tumor condition requiring disposal of carcass and viscera . 09-0834 This young chicken has round, white nodules, with smooth borders, throughout the liver and spleen. The heart appears normal. Such nodules are compatible with the avian leukosis complex, which is a generalized tumor condition requiring disposal of carcass and viscera . 07-0885 The skin of a young chicken with a round, white to tan nodule greater than one millimeter in greatest dimension, with smooth borders, centered on a 07-0194 The skin of a young chicken with a round, white to tan nodule greater than one millimeter in greatest dimension, with smooth borders, centered on a feather follicle. Such a ", "21 feather follicle. Such a nodule is compatible with the avian leukosis complex, which is a generalized tumor condition requiring disposal of carcass and viscera. nodule is compatible with the avian leukosis complex, which is a generalized tumor condition requiring disposal of carcass and viscera.

**VI. LOCALIZED DISEASE OR OTHER CONDITIONS AFFECTING POULTRY**

**CARCASSES**

A. Contamination During slaughter operations, visible fecal material from the digestive tract is the main way that disease-causing bacteria can be spread to the portions of the carcass that are edible (fit to be eaten by humans). Bacteria that can cause human illness are found in the digestive tract and on the skin of birds when the birds come to slaughter. To prevent fecal material from spreading to edible portions of the carcasses, special care must be taken during handling and sanitary dressing procedures. For these reasons FSIS inspectors enforce a zero tolerance standard for visible fecal material on carcasses before the chiller. FSIS also requires that the establishment put into place effective sanitary dressing procedures throughout its slaughter process to prevent contamination of carcasses and parts. Carcasses that are accidentally contaminated with fecal (or digestive tract) material during slaughter can be reconditioned, if they are reprocessed in a sanitary manner to remove all visible contamination by either online or offline reprocessing procedures. Note: Carcasses that are excessively contaminated are unwholesome and must be disposed of properly to ensure they are not used as human food. What to Look For: \u2022 Feces identification o Color is yellow to green, brown or white, o semi-solid to a paste in consistency, and o may or may not have plant material. \u2022 Ingesta identification o Color varies with the diet, o Solid or granular consistency and sometimes has digestive fluids and o Identifiable plant material.", "22 10-0174 Digestive tract content is present on the exposed muscle tissue of a young chicken. Digestive tract contents that require removal from carcass and viscera 10-0192 Digestive tract content is present on the skin and exposed muscle tissue of a young chicken. Digestive tract contents that require removal from carcass and viscera 10-0399 Feces is present on the skin of a young chicken. Color is green, has a semi-solid to paste consistency and does not have plant material. Feces requires removal from carcass and viscera.", "23 B. Keratoacanthoma and Other Tumors

Keratoacanthoma and other tumors is referring to tumors other than the leukosis tumors that were previously discussed. The most common tumor in young chickens is a keratoacanthoma, which is a tumor of the skin that looks like a miniature crater or ulcer. This tumor can range from one small tumor to many large tumors that overlap or join together (coalesce). If the carcass has so many of these tumors that they coalesce, then the entire carcass and its viscera are unwholesome and must be disposed of properly to ensure they are not used as human food. If there are only a few, smaller tumors, then the tumors can be trimmed and disposed of properly as described above. After the tumors are trimmed, the rest of the carcass can proceed down the line to the FSIS online inspector. What to Look For: \u2022 Single tumors or several small tumors that are localized and can be trimmed; \u2022 Many tumors that are intermediate to large in size and coalesce are unwholesome, and the carcass are unwholesome and must be disposed of properly as described above. 10-1080 This is an adequately fleshed young chicken. Several round, crater-shaped masses extend throughout the skin. Such masses are compatible with localized tumors and require trimming. 09-0879 This is an adequately fleshed young chicken with coalescing, multiple, round, crater-shaped masses extending throughout the skin. Coalescing tumors require disposal of the entire carcass. There are many other types of tumors that occur occasionally in young poultry. If one tumor is very large in size and disrupts normal body functions, for example, taking up too much space in the body then the entire carcass and viscera are unwholesome and must be disposed of properly to ensure they are not used as human food. If there is, "24 more than one tumor of the same kind, which indicates that the tumor has spread (metastasized) then the carcass and its viscera are unwholesome and must be disposed of properly. Localized tumors can be trimmed (if just on the carcass) or all of viscera disposed of properly (if just on the viscera). What to Look For: \u2022 If one very large tumor or more than one tumor of the same type, then dispose of carcass and viscera properly to ensure they are not used as human food. \u2022 If the tumor is not very large and has not spread then trim tumor if on the carcass, or dispose of viscera only if located on the viscera. 05-1045 This is an adequately fleshed young chicken with a solitary mass extending out from the skin. Such a mass is compatible with a localized tumor and requires trimming. 09-0579 This is an adequately fleshed young chicken. Multiple, round, white masses extend out of the skin. Such masses are compatible with localized tumors and require trimming. 10-1100 This is a well-fleshed young chicken. Multiple, black masses are present in the skin. Such masses are compatible with localized tumors and require trimming. 09-0275 03-0681 10-0151", "25 This is an adequately fleshed young chicken. A round, white mass extends out of the kidney. Such a mass is compatible with a localized tumor and requires trimming. This is an adequately nourished young chicken with a quality defect \u2022 retained lung. A round, red mass compatible with a localized tumor extends out of the kidney and requires trimming. This is a well-fleshed young chicken. A single, firm mass is present under the skin of the thigh. Such a mass is compatible with a localized tumor and requires trimming. 09-0842 Multiple masses filled with blood are visible in the liver of this young chicken. A large ruptured mass is visible in the center of the liver. Such masses are compatible with localized tumors and require trimming. 10-1039 This is a well-fleshed young chicken. A solitary mass is present in the skin. Such a mass is compatible with a localized tumor and requires trimming. 10-0923 Multiple black masses are visible in the liver and lung of this young chicken. Such masses are compatible with localized tumors and requires trimming. C. Airsacculitis In addition to lungs, birds have balloon-like

\u201cair sacs\u201d throughout the inside of their chest and belly (abdomen). (See Figure 2. In the Appendix.) The air sacs move the air in and out allowing the bird to breathe. When the carcasses are opened to pull out the viscera, the air sacs are torn apart, so they do not appear as balloons when being sorted. There are 6 pairs of air sacs in chickens and 5 pairs in turkeys. Normal air sacs appear very clear with thin membranes or linings. Normal air sacs are not very noticeable. Airsacculitis is an inflammation of the air sacs that occurs when the bird is fighting off a respiratory tract infection or disease. The signs of inflammation that can be observed are a red color, swelling, and increased production of fluid. In the early (acute) stages of the disease, the air sacs can have a slight, cloudy appearance with a small amount of watery fluid, and only the air sacs are affected. If the disease has been going on for awhile (chronic), then the air sacs may appear thickened and have large amounts of", "26 thick, white to cream-color fluid (exudate). The fluid may also have a cheesy- pus-like appearance. Other organs, such as the liver, lungs, and heart may also show these signs. In carcasses affected with airsacculitis, all of the diseased tissues and fluids may be removed either by online or by offline salvage (vacuum or cut-up) procedures. The kidneys also must be removed and disposed of properly. If disease has spread from the air sacs to the bones of the shoulder joint, all affected tissues must be removed and disposed. After removal of affected tissues online or offline, the carcasses can go down the line to the FSIS online carcass inspector. Carcasses with airsacculitis and signs of systemic change (Sep\Tox) are to be disposed of properly to ensure they are not used as human food. Additionally, carcasses that are extensively affected with air sac such that the inner surfaces of the carcass cannot be observed or the carcass cannot be salvaged are to be disposed of properly as described above. What to Look For: \u2022 If a carcass has early stages of airsacculitis with slightly cloudy air sacs and a small amount of fluid, then the affected tissues and kidneys should be removed. \u2022 If a carcass has thickened air sacs: large amounts of white to cream-colored fluid; or dry, yellow, cheesy pus, and the visceral organs are affected, then the affected tissues, viscera, and kidneys should be removed. \u2022 If airsacculitis has spread from the air sacs to the bones in the shoulder joint, then the affected tissues must be removed and disposed of properly. \u2022 If carcasses have airsacculitis and signs of systemic change (Sep\Tox) then the entire carcass and viscera are unwholesome and must be removed for proper disposal. \u2022 If carcasses are extensively affected with airsacculitis such that the inside of the carcass cannot be observed, or the carcass cannot be salvaged, then the entire carcass and viscera must be disposed of properly as described above. , 10-1052 10-1051 10-1054", "27 The thoracic air sac of this young chicken contains exudates, which evidence inflammation of the air sac and adjacent tissue. Inflamed tissue is unfit for human food. The abdominal air sac of this young chicken contains exudates, which evidence inflammation of the air sac and adjacent tissue. Inflamed tissue is unfit for human food. The abdominal air sac and sac around the heart of this young chicken contain exudates, which evidence inflammation. The general outline of the liver is not a smooth, unbroken curve, which is suggestive of fibrosis. Inflamed tissue is unfit for human food. 10-2218 The abdominal air sac of this young turkey contains exudates, which evidence inflammation of the air sac and adjacent tissue. Inflamed tissue is unfit for human food. 10-1424 The abdominal air sac of this young turkey contains exudates, which evidence inflammation of the air sac and adjacent tissue. Inflamed tissue is unfit for human food. 10-1074 The abdominal air sac of this young chicken contains exudates, which evidence inflammation of the air sac and adjacent tissue. Inflamed tissue is unfit for

human food. D. Inflammatory Process Inflammatory Process (IP) is a term to describe inflammation in or under the skin caused by bacteria. Most often the bacteria enter through breaks in the skin caused by birds pecking one another. Usually IP appears as yellow, scabbed areas between the skin and the underlying tissues. IP may also appear as a yellow cheesy material or dried brownish flakes under the skin. In severe cases the skin will have a burnt waffle appearance. IP can occur anywhere on the bird but is most often seen around the vent, abdominal fat flaps, or side of the bird. These localized areas of infection generally can be trimmed to remove affected tissues. IP can also spread under the skin to breast muscles, and for this reason, these carcasses should be thoroughly examined to ensure that all affected portions are removed. If most of the carcass is affected by IP, then the entire carcass and viscera are unwholesome and must be disposed of properly to ensure they are not used as human food." "28 If the carcass affected with IP also has signs of systemic change (Sep\Tox), then the entire carcass and viscera are unwholesome and must be disposed of properly as described above. What to Look For: \u2022 Localized IP: look for areas of yellow, cheesy material found in the vent area, side of the carcass, or abdominal flaps. These areas must be trimmed to remove the unwholesome tissues. \u2022 Generalized IP: if the areas of yellow, cheesy material has travelled down to the breast, and most of the carcass is affected or the carcass shows signs of systemic change, then the entire carcass and viscera must be disposed of properly as described above. 06-0305 This is a well-nourished young chicken with ample body fat and no obvious blemishes. A well-defined area across the back is dark yellow to brown. Such a discoloration is compatible with inflammation. Tissue affected by inflammation is unfit for human food. 06-0338 This is a well-nourished young chicken with ample body fat and no obvious blemishes. A well-defined area on the vent flap is dark yellow to brown. Such a discoloration is compatible with inflammation. Tissue affected by inflammation is unfit for human food. 03-0679 The connective tissue below the skin of this young chicken contains localized exudates. The skin appears normal. Exudates evidence inflammation and inflamed tissue is unfit for human food." "29 10-1544 This is an adequately fleshed young turkey with quality defects \u2013 surface blemishes. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The scabs and open sores with red margins are consistent with inflammation 10-1502 The skin of this young turkey over the drumstick appears thick, wet, and yellow. The appearance of the skin is consistent with exudates and inflammation. 10-1490 This is a well-nourished young turkey with ample body fat and no obvious blemishes. The majority of the skin appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The thick, wet, yellow appearance of the skin over the breast is consistent with exudates and inflammation. E. Turkey Osteomyelitis Complex Turkey Osteomyelitis Complex (TOC) affects the cartilage of bones and surrounding tissues and joints. The cause is unknown. Any bone may have TOC, but most often the knee, shoulder or hip joints are affected. The swollen joints and soft tissues may be affected mildly or more severely. A green fringed liver may indicate TOC or some other condition. Additionally, carcasses affected with TOC may not have a green liver. For each flock, special examinations are conducted by cutting into the joints to determine whether the flock is affected with TOC. If the flock is affected with TOC, then sorters should identify the carcasses and viscera with swollen joints or green livers for the establishment to perform additional procedures to remove the unwholesome tissue. All

affected tissues must be removed from TOC carcasses. If it is not possible to do so, or if the carcass is showing signs of systemic change (Sep\Tox), the entire carcass and associated viscera are to be disposed of properly to ensure they are not used as human food.", "30 What to Look For: \u2022 Green fringed livers or swollen joints, especially the knee, hip, or shoulder, may indicate TOC, but it also may indicate other conditions. Carcasses are to be identified for further examination. \u2022 Enlarged livers, soft livers with smooth surfaces, or green streaked livers may all be signs of TOC. \u2022 Carcasses with green livers or swollen joints and with signs of systemic change are unwholesome and the carcasses and viscera must be disposed of properly. 03-0739 The bone marrow cavity of this young turkey appears white with an open area of tan fluid. This appearance is suggestive of necrosis and exudates, which is consistent with inflammation. 10-2234 This fibrotic liver in a young turkey contains excess bile. The liver appears purple with white spots and blotches. The general outline is not a smooth, unbroken curve. The texture of a fibrotic liver is firm. The fibrosis and excess bile does make the liver unfit for human food. 10-2256 This fibrotic liver in a young turkey contains excess bile. The liver appears purple with white spots and blotches. The general outline is not a smooth, unbroken curve. The texture of a fibrotic liver is firm. The fibrosis and excess bile does make the liver unfit for human food. The fat attached to the gizzard appears thin, pink, and transparent, which is suggestive of a wasting condition. F. Synovitis Synovitis is inflammation of the tissues around a joint. The hock joint is most often affected. Synovitis is caused by either physical injury or infection. The joints appear swollen and may have a red or yellow appearance and contain extra visible fluid. The fluid can range from a clear watery fluid to a severe pus-like fluid that is yellowish in", "31 color and creamy or flaky. The tendons may also be swollen. The affected legs are unwholesome and must be removed from the carcass and disposed of properly. A carcass with synovitis is wholesome unless it also shows systemic changes. If there is no systemic change, then all affected synovial tissues should be removed. 03-0893 The soft tissue around the joint in this young chicken is swollen. The skin appears wet and yellow. This appearance is suggestive of inflammation in the tendons and skin. 09-0811 The drumstick from this young turkey has a prominent swelling under the skin. Such swelling is consistent with the presence of exudates in the underlying tendons. Inflamed tissue is unfit for human food. 10-1203 A prominent greenish swelling is visible next to the kidney in this young chicken. The swelling and discoloration are consistent with the presence of exudates in the hip joint. Inflamed tissue is unfit for human food. 10-1342 The upper drumstick from this young turkey is normal. The lower drumstick has a 10-1383 This is an adequately nourished young turkey with minimal quality defects \u2013 retained cuticle and surface", "32 prominent swelling of the joint and the skin is thick and yellow. Such swelling and discoloration is consistent with the presence of exudates in the underlying tendons and skin. Inflamed tissue is unfit for human food. blemishes. A prominent swelling is visible over the thighbone. Such swelling is consistent with the presence of exudates in the underlying tendons. Inflamed tissue is unfit for human food. G. Mutilation Mutilated means the carcass is torn apart shredded or damaged by the slaughter processing equipment. Any part or organ that is mutilated and can be trimmed from the carcass is unwholesome and must be disposed of properly to ensure that it is not used as human food. If the entire carcass is affected, then the carcass is unwholesome and would be disposed of properly as described above. The viscera is wholesome and could be saved for edible product. What to Look For: \u2022 If the entire carcass is affected, then it is unwholesome and must be

disposed properly as described above; but the viscera is wholesome. \u2022 If part of the carcass is affected, then the affected tissues are unwholesome and must be trimmed and disposed of properly as described above. 10-0127 The skin and muscle tissue on this young turkey is mutilated. Mutilated tissue is contaminated and unfit for 10-1254 The muscle tissue on this young turkey is mutilated. Mutilated tissue is contaminated and unfit for", "33 human food. human food. H. Overscald Often overscald carcasses are found after the picking line breaks down, and the carcasses are held in the scalding tank too long. When both the top breast muscle and deep breast muscle have a cooked, white, dry texture, the carcasses are unwholesome and unfit for human food and should be disposed of properly along with its associated viscera to ensure they are not used as human food. Sometimes only the top layer of breast muscle appears white. This hard scald will likely show whitening only of the top layer of breast muscle. The hard scalded carcasses should not be disposed for overscald but should be trimmed to remove any affected tissue, and the viscera if it appears to be cooked. What to Look For: \u2022 If both top and deep breast muscles are white and appear cooked: then dispose properly as described above of the entire carcass and viscera. \u2022 If only the top layer of breast muscle is whitened: it may be trimmed. I. Ascites Ascites is an abnormal condition that is caused by the heart being overworked. As a result a clear to amber colored fluid collects inside the bird\u2019s body cavity (chest and abdomen). The fluid may also be found in the sac around the heart and the liver may appear swollen. It occurs in young chickens because of growing very fast. The fluid in the body of the carcass should be removed if the inside of the cavity cannot be viewed. If the carcass shows only signs of ascites, then the viscera is unwholesome and must be disposed of properly. The carcass can go down the line to the FSIS online inspector. If the carcass shows signs of ascites and systemic change (Sep\Tox) or any other disease condition, the entire carcass and viscera are unwholesome and must be disposed of properly to ensure the carcass and viscera are not used as human food.", "34 10-1862 A clear, watery fluid is visible in the body cavity of young chicken. Such fluid retention is compatible with ascites. 03-0869 Normal kidneys in a young chicken with blood tinged gelatinous fluid in the body cavity. Such fluid is compatible with ascites. 10-0977 A clear, watery fluid is visible inside the capsule surrounding the heart of young chicken. Such fluid retention is compatible with ascites. J. Breast Atrophy This condition has several names, including green atrophy, green breast, and green muscle degeneration. Atrophy means \u201cwasting away or to decrease in size.\u201d The deep breast muscle on either one or both sides of the keel bone is affected. The condition is found mostly in broad breasted hen turkeys older than five months. The breast (on one or both sides) will appear wasted away as if it has shrunken away from the keel bone. The change in the muscle could look like a small depression or dip, or it could look very extreme or obvious. The deep muscle will be greenish in color, and it will feel hard with a wood-like texture. The breast muscle is unwholesome and must be removed and disposed of properly. K. Turkey Leg Edema Turkey Leg Edema occurs mostly in heavy hen turkeys (older than 25 weeks) from August to October. The thigh may appear very white. The thigh will feel slick on the outside, and gas bubbles may be felt under the skin. Turkey leg edema is an inflammation of the leg. The affected leg is unwholesome and is to be disposed of properly. If there are signs of systemic change in the carcass, then the carcass and viscera are unwholesome and must be disposed of properly to ensure they are not used as human food. L. Bruises A bruise comes from physical trauma or damage to blood vessels and the leakage of blood into the surrounding

tissue. The color of a bruise varies from red to green to black depending on the age of the bruise. Bruises that affect most or all of the whole carcass or carcasses showing signs of systemic change are unwholesome and must be disposed of properly. If bruises are localized, they may be removed by trimming. NOTE: If sorters find increased numbers or clusters of severely bruised carcasses at the sorting station, this finding may be an indication that there has been a breakdown in the establishment's good commercial practices. Appropriate establishment personnel should be notified of the findings.

10-0210 This is a well-nourished young chicken with ample body fat and minimal blemishes. A well-defined area across the breast and wing is dark red. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food.

07-0263 This is a well-nourished young chicken with ample body fat and minimal blemishes. A well-defined area across the breast is dark red. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food.

10-1625 The skin of the hip in this young turkey is dark red. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food.

","36 09-0661 The skin of this young chicken is normal with quality defects retained feathers. A well-defined area across the back of the wing is dark red. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food.

10-0440 The skin of the drumstick in this young chicken is dark red. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food.

10-0443 The skin of the drumstick in this young chicken is dark red to green. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food.

M. Parts Disposition Generally, when carcasses are affected with localized disease or other conditions, the affected carcass, part or viscera is unwholesome and must be disposed of properly to ensure that they are not used as human food. If the unwholesome portions or parts can be effectively removed, the remainder of the carcass is wholesome. The following are some examples of some organs or parts that are unwholesome and must be removed and disposed of properly, but the rest of carcass is wholesome. Dispose properly to ensure the livers with the following unwholesome conditions are not to be used as human food:

\u2022 Fatty degeneration: Have visible, well defined light spots. (Livers with a uniform yellowish color throughout the liver are the result of diet and are wholesome.)

\u2022 Scar tissue due to disease (cirrhosis)

\u2022 Extensive small hemorrhages

\u2022 Inflammation (redness, swelling)

\u2022 Abscess

\u2022 Contamination from bile

\u2022 Green or other discoloration

\u2022 Granuloma

\u2022 One Leukosis tumor (also dispose of carcass and all viscera)

\u2022 One non-leukosis tumor

\u2022 Areas of necrosis (cells are dead because of death or injury)",

","37 03-0673 This normal liver in a young chicken contains excess fat. The liver appears tan with spots and blotches. The general outline is a smooth, unbroken curve. The texture of a fatty liver is soft. The excess fat does not make the liver unsafe or unfit for human food.

07-0296 This normal liver in a young chicken contains excess fat. The liver appears tan with spots and blotches. The general outline is a smooth, unbroken curve. The texture of a fatty liver is soft. The excess fat does not make the liver unsafe or unfit for human food.

10-0885 This normal liver in a young chicken contains excess fat. The liver appears tan with spots and blotches. The general outline is a smooth, unbroken curve. The texture of a fatty liver is soft. The excess fat does not make the liver unsafe or unfit for human food.

10-0929 This inflamed liver in a young chicken is fibrotic. The liver appears reddish-brown with spots and blotches. The general outline is not a smooth, unbroken curve. The texture of an inflamed, fibrotic liver is firm

to hard. 10-0884 This inflamed liver in a young chicken is fibrotic and enlarged. The liver appears uniformly tan. The general outline is a smooth, unbroken curve. The texture of an enlarged, inflamed, 10-0821 This inflamed liver in a young turkey is fibrotic and enlarged. The liver appears uniformly tan. The general outline is a smooth, unbroken curve. The texture of an enlarged, inflamed, fibrotic liver is hard. The", "38 The fibrosis makes the liver unfit for human food. fibrotic liver is hard. The fibrosis makes the liver unfit for human food. fibrosis makes the liver unfit for human food. 03-0667 This inflamed liver in a young chicken contains small granuloma throughout. The liver appears tan with spots and blotches. The general outline is a smooth, unbroken curve. The texture of an inflamed liver is soft to firm. The granuloma make the liver unfit for human food. 10-0907 This inflamed liver in a young chicken contains small granuloma throughout. The liver appears purple with spots and blotches. The general outline is a smooth, unbroken curve. The texture of an inflamed liver is soft to firm. The granuloma make the liver unfit for human food. The slight green tinge is suggestive of bile retention. 10-0835 This inflamed liver in a young turkey contains large granuloma throughout. The liver appears purple with spots and blotches. The general outline is not a smooth, unbroken curve. The texture of an inflamed liver is soft to firm. The granuloma make the liver unfit for human food. The slight green tinge is suggestive of bile retention. 10-0779", "39 This normal liver in a young turkey contains excess bile. The liver appears purple with green spots and blotches. The general outline is a smooth, unbroken curve. The texture of a normal liver is firm. The excess bile does make the liver unfit for human food. Kidneys are unwholesome and unfit and must be removed when: \u2022 from carcasses affected with airsacculitis in the abdominal area; \u2022 the liver is unwholesome because of disease; \u2022 the viscera is unwholesome; or \u2022 the kidneys are swollen. 09-0491 The kidneys in this young chicken are uniformly enlarged and pale in color. The uniform enlargement and color change are compatible with a growth disturbance and significant fibrosis. Tissue affected by disturbances of growth and significant fibrosis are unfit for human food. Salpingitis: the oviduct tubes are swollen and filled with firm cheesy fluid (normally the tubes are not seen, but when infected they are visible). All affected tissues are", "40 unwholesome and must be removed and disposed of properly. If the carcass shows signs of systemic change (Sep\Tox) then the carcass and viscera is unwholesome and must be disposed of properly. 06-0257 The oviduct of this young chicken contains white exudates. The oviduct is inflamed and unfit for human food. 09-0935 The oviduct of this young chicken contains white exudates. The oviduct is inflamed and unfit for human food. 10-0694 The oviduct of this young turkey contains white exudates. The oviduct is inflamed and unfit for human food. Pericarditis: the sac around the heart is swollen, cloudy, or filled with fluid. All affected tissues are unwholesome and must be removed and disposed of properly. If the carcass shows signs of systemic change (Sep\Tox) then the carcass and viscera is unwholesome and must be disposed of properly. 10-0988 This inflamed heart in a young chicken evidences the presence of exudates in the sac around the heart and on 10-0992 This inflamed heart in a young chicken evidences the presence of exudates on the 10-0987 This inflamed heart in a young chicken evidences the presence of exudates in the sac around the heart and on", "41 the surface of the heart. The presence of exudates makes the heart unfit for human food. surface of the heart. The presence of exudates makes the heart unfit for human food. surface of the heart. The presence of exudates makes the heart unfit for human food.", "42 Appendix: ANATOMY OF POULTRY Anatomy refers to the parts of a poultry bird or carcass. Outside

(External) Anatomy Figure 1. Outside Anatomy shows the parts of a chicken carcass after the feathers are removed and before the carcass is opened to remove the viscera (guts). The comb and wattles are on the head of poultry and are largely for looks. They vary in size and color based on type and breed, and whether they are females or males. Snoods and whiskers (beards) are external structures only found in turkeys.","43 Feathers cover almost the entire surface of the bird. They grow from follicles, which are organized into groups or zones and are called feather tracts (see shaded areas of Figure 1. The skin of chickens is thinner and more delicate than that of animals. In addition, the color of the skin depends on the type or breed of poultry, age, and diet. The skin may also be affected by the scalders used to loosen feathers. The neck attaches the head to the body. The wings are the \u201carms\u201d of the bird. The thigh is the upper leg and the drumstick is the lower leg. Meat from both of them is commonly called \u201cdark meat.\u201d The breast (\u201cwhite meat\u201d) is located in the front of the bird and contains large muscles. The hock joint is between the lower leg and the paw. The paws are the feet of the bird. The preen or oil gland is an important gland and is located near the tip of the tail. When poultry are preening, they take oil from this gland and apply it to their feathers. Inside (Internal) Anatomy The trachea or windpipe is the structure that carries air into the bird. Air passes through the trachea and into the air sacs. These structures are very thin, colorless membranes that when filled with air look like tiny balloons inside the body. The air sacs come in pairs, and the number of pairs is 5 in chickens and 4 in turkeys. The air sacs are round sacs that also have tiny finger like projections that go into certain bones and are shown in Figure 2. Air Sacs.","44 The digestive tract of the bird are shown in Figure 3. Digestive Tract of Fowl. The digestive tract of the chicken begins with the mouth or beak, which does not contain lips or teeth. The mouth is connected to the esophagus, also called the gzzle or gullet, which connects with the Crop (or craw) where feed is stored. After the crop is the stomach of birds. This stomach is called the true stomach (or proventriculus) and digests proteins. Next is the gizzard or the ventriculus. Its function is to grind the food. Often in healthy birds, there are large amounts of fat around the gizzard. The small and then large intestines come next and end at the cloaca. The cloaca opens to outside of the bird in an area called the vent. There is also a small sac on the side of the cloaca","45 called the rosebud. The rosebud is seen when the equipment cutting around the vent accidentally cuts into it. Birds that are healthy and well nourished usually have large amounts of fat throughout their tissues. The areas storing the fat are the abdominal or belly area, the vent flaps, and the gizzard and the heart. The normal liver has two lobes and each lobe is drained by a bile duct. One duct is larger and makes the gall bladder. The color of the liver depends on the fat content or bile content. Poultry do not contain a urinary bladder, but they do have two kidneys, one on each side and are set into the back bone of the bird. Ureters carry urinary waste from the kidneys to the cloaca where it leaves the bird. Bones: The bones of chickens are shown in Figure 4. Skeleton of domestic fowl.","46 The vertebral column (spine) is made up of many small bones and is divided into several parts: the neck, chest, lower back or pelvic and the tail. The neck has a bone called a wishbone or pulley bone. The bone has two branches and an air sac lies between the two branches. The shoulder blade is a bone that lies on top of each side of the rib cage. The shoulder blade with a bone from the wings and the coracoid bone makes up the shoulder joint. There are several bones in the wing. The bones at the very end of the wing are called the wing tip, and it is often broken during the slaughter process. The knee joint is made of the thigh bone

and the drumstick. The upper leg of the chicken is the thigh bone just as in animals. The drumstick is the lower leg, again just as in animals. The next bone down from the drumstick is the shank bone. The hock joint is formed from the drumstick and the shank. The hock joint is normally opened up for sorting. The shank joins the paws (or toes). The keel or breast bone is a single large bone on the bottom surface of the bird." , "47 Image Descriptions 03-0667: This inflamed liver in a young chicken contains small granuloma throughout. The liver appears tan with spots and blotches. The general outline is a smooth, unbroken curve. The texture of an inflamed liver is soft to firm. The granuloma make the liver unfit for human food. 03-0673: This normal liver in a young chicken contains excess fat. The liver appears tan with spots and blotches. The general outline is a smooth, unbroken curve. The texture of a fatty liver is soft. The excess fat does not make the liver unsafe or unfit for human food. 03-0679: The connective tissue below the skin of this young chicken contains localized exudates. The skin appears normal. Exudates evidence inflammation and inflamed tissue is unfit for human food. 03-0681: This is an adequately nourished young chicken with a quality defect \u2013 retained lung. A round, red mass compatible with a localized tumor extends out of the kidney and requires trimming. 03-0715: The skin over the neck on this young chicken is dark red. A visible cut across the cervical vessels is absent. The red skin discoloration and absence of a cervical cut are consistent with a cadaver - a bird that was still breathing when it entered the scald tank. Cadavers are unfit for human food. 03-0732: This normal heart in a young turkey appears red with uniformly white fat where the arteries and veins attach. The surface exhibits spots and blotches. The general outline is a smooth, unbroken curve except where the arteries and veins attach. 03-0739: The bone marrow cavity of this young turkey appears white with an open area of tan fluid. This appearance is suggestive of necrosis and exudates, which is consistent with inflammation. 03-0869: Normal kidneys in a young chicken with blood tinged gelatinous fluid in the body cavity. Such fluid is compatible with ascites. 03-0893: The soft tissue around the joint in this young chicken is swollen. The skin appears wet and yellow. This appearance is suggestive of inflammation in the tendons and skin. 04-0536: This young chicken evidences necrosis and hemorrhage in the liver and spleen. The liver appears reddish-brown. The general outline is a smooth, unbroken curve. The linear white areas are soft and suggestive of dead tissue. The dark red areas in the liver and dark purple spleen are characteristic of hemorrhage. The parallel orientation of the white and dark red tissue in the liver is suggestive of swelling caused by the liver pressing against the ribs. Necrosis and hemorrhage are consistent with a generalized disease condition. 05-0899: These are two adequately fleshed young chickens with ample body fat, normal skin, and minimal blemishes. The carcass on the right has normal skin color. The skin over the breast, thigh, and drumstick on the carcass on the left is dark red. The red skin discoloration of the otherwise normal carcass is consistent with a bird that was still breathing when it entered the scald tank. 05-1045: This is an adequately fleshed young chicken with a solitary mass extending out from the skin. Such a mass is compatible with a localized tumor and requires trimming. 06-0228: This normal liver in a young turkey appears brown with light spots and blotches. The general outline is a smooth, unbroken curve. The texture of a normal liver is firm." , "48 06-0257: The oviduct of this young chicken contains white exudates. The oviduct is inflamed and unfit for human food. 06-0298: This is an adequately fleshed young chicken with ample body fat, normal skin, and minimal blemishes. The overall dark appearance evidences dehydration. The prominent dark red discoloration of one side of the carcass is suggestive of

blood setting in the carcass. Depending on the ambient temperature and time since death, the carcass might be cool and\or stiff. The overall condition is consistent with a bird that was dead on arrival. 06-0305: This is a well-nourished young chicken with ample body fat and no obvious blemishes. A well-defined area across the back is dark yellow to brown. Such a discoloration is compatible with inflammation. Tissue affected by inflammation is unfit for human food. 06-0316: The skin of this young chicken appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The minor quality defects \u2013 feather remnant and scratches \u2013 do not make the skin unsafe or unfit for human food. 06-0338: This is a well-nourished young chicken with ample body fat and no obvious blemishes. A well-defined area on the vent flap is dark yellow to brown. Such a discoloration is compatible with inflammation. Tissue affected by inflammation is unfit for human food. 07-0159: This normal heart in a young chicken appears reddish-tan with uniformly white fat where the arteries and veins attach. The surface color appears uniform. The general outline is a smooth, unbroken curve except where the arteries and veins attach. 07-0194: The skin of a young chicken with a round, white to tan nodule greater than one millimeter in greatest dimension, with smooth borders, centered on a feather follicle. Such a nodule is compatible with the avian leukosis complex, which is a generalized tumor condition requiring disposal of carcass and viscera. 07-0242: These normal spleens from young chickens are round to oval. Their color varies from red to tan. The surface color appears uniform or exhibits spots and blotches. 07-0263: This is a well-nourished young chicken with ample body fat and minimal blemishes. A well-defined area across the breast is dark red. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food. 07-0296: This normal liver in a young chicken contains excess fat. The liver appears tan with spots and blotches. The general outline is a smooth, unbroken curve. The texture of a fatty liver is soft. The excess fat does not make the liver unsafe or unfit for human food. 07-0564: This young chicken evidences hemorrhage in the heart. The general outline is a smooth, unbroken curve except where the arteries and veins attach. The dark red surface blotches are characteristic with hemorrhage, which is consistent with a generalized disease condition. 07-0851: This young chicken evidences adequate body fat and normal skin. The enlarged joint at the end of the drumstick is suggestive of inflammation. The uniformly dark muscle tissue is suggestive of extreme loss of body fluids. Inflammation with loss of body fluids are compatible with wasting, which is a generalized disease condition. 07-0877: This is a well-nourished young chicken with ample body fat and minimal blemishes. The body is plump. The general form of the wings and hips is round. The skin appears uniform in color, moist, and thick. The underlying muscle tissue is barely visible through the skin. The yellow color is due to yellow plant pigments in the feed." 49 07-0885: The skin of a young chicken with a round, white to tan nodule greater than one millimeter in greatest dimension, with smooth borders, centered on a feather follicle. Such a nodule is compatible with the avian leukosis complex, which is a generalized tumor condition requiring disposal of carcass and viscera. 09-0275: This is an adequately fleshed young chicken. A round, white mass extends out of the kidney. Such a mass is compatible with a localized tumor and requires trimming. 09-0491: The kidneys in this young chicken are uniformly enlarged and pale in color. The uniform enlargement and color change are compatible with a growth disturbance and significant fibrosis. Tissue affected by disturbances of growth and significant fibrosis are unfit for human food. 09-0579: This is an

adequately fleshed young chicken. Multiple, round, white masses extend out of the skin. Such masses are compatible with localized tumors and require trimming. 09-0625: This young turkey evidences necrosis in the liver. The liver appears red. The general outline is a smooth, unbroken curve. The linear white areas are soft and suggestive of dead tissue. The parallel orientation of the white tissue is suggestive of swelling caused by the liver pressing against the ribs. Necrosis is consistent with a generalized disease condition. 09-0661: The skin of this young chicken is normal with quality defects \u2013 retained feathers. A well-defined area across the back of the wing is dark red. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food. 09-0690: These normal livers from two young turkeys appear reddish-brown with light spots and blotches. The general outline is a smooth, unbroken curve. The dry appearance of the liver on the left is a post mortem artifact. The texture of a normal liver is firm. 09-0691: These two normal hearts from two young turkeys appear red with uniformly white fat where the arteries and veins attach. The surface exhibits spots and blotches. The general outline is a smooth, unbroken curve except where the arteries and veins attach. 09-0693: These normal spleens from young turkeys are round to oval. Their color varies from red to tan. The surface color appears uniform or exhibits spots and blotches. 09-0794: This normal bone marrow from a young turkey appears uniformly red with a fine texture. 09-0811: The drumstick from this young turkey has a prominent swelling under the skin. Such swelling is consistent with the presence of exudates in the underlying tendons. Inflamed tissue is unfit for human food. 09-0834: This young chicken has round, white nodules, with smooth borders, throughout the liver and spleen. The heart appears normal. Such nodules are compatible with the avian leukosis complex, which is a generalized tumor condition requiring disposal of carcass and viscera. 09-0842: Multiple masses filled with blood are visible in the liver of this young chicken. A large ruptured mass is visible in the center of the liver. Such masses are compatible with localized tumors and requires trimming.. 09-0879: This is an adequately fleshed young chicken with coalescing, multiple, round, crater-shaped masses extending throughout the skin. Coalescing tumors require disposal of the entire carcass 09-0904: This young chicken has round, white nodules, with smooth borders, throughout the liver and spleen. The heart appears normal. Such nodules are compatible with the avian", "50 leukosis complex, which is a generalized tumor condition requiring disposal of carcass and viscera. 09-0910: This young chicken has round, white nodules, with smooth borders, throughout the liver and spleen. The heart appears normal. Such nodules are compatible with the avian leukosis complex, which is a generalized tumor condition requiring disposal of carcass and viscera. 09-0921: This young chicken evidences necrosis in the liver and hemorrhage in the spleen. The liver is soft with white blotches suggestive of dead tissue. The general outline is a smooth, unbroken curve. The dark purple and soft spleen is characteristic of hemorrhage. The heart appears normal. Necrosis and hemorrhage are consistent with a generalized disease condition. 09-0935: The oviduct of this young chicken contains white exudates. The oviduct is inflamed and unfit for human food. 10-0127: The skin and muscle tissue on this young turkey is mutilated. Mutilated tissue is contaminated and unfit for human food. 10-0151: This is a well-fleshed young chicken. A single, firm mass is present under the skin of the thigh. Such a mass is compatible with a localized tumor and requires trimming 10-0174: Digestive tract content is present on the exposed muscle tissue of a young chicken. Digestive tract contents require removal from the carcass and viscera. 10-0192: Digestive tract content is present on the skin and exposed muscle tissue of a

young chicken. Digestive tract contents require removal from the carcass and viscera. 10-0210: This is a well-nourished young chicken with ample body fat and minimal blemishes. A well-defined area across the breast and wing is dark red. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food. 10-0236: This normal joint surface and tendon in a young chicken are white. The surface is shiny. 10-0399: Feces is present on the skin of a young chicken. Color is green, has a semi-solid to paste consistency and does not have plant material. Feces requires removal from carcass and viscera. 10-0403: The skin of this young chicken appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The minor quality defects \u2013 feather remnants and red blemishes \u2013 do not make the skin unsafe or unfit for human food. 10-0440: The skin of the drumstick in this young chicken is dark red. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food. 10-0443: The skin of the drumstick in this young chicken is dark red to green. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food. 10-0694: The oviduct of this young turkey contains white exudates. The oviduct is inflamed and unfit for human food. 10-0706: The heart of this young turkey appears wet, and off-white. The fat, normally visible where the arteries and veins attach, is gone. The general outline is no longer a smooth, unbroken curve. This is compatible with wasting, which is a generalized disease condition. 10-0779: This normal liver in a young turkey contains excess bile. The liver appears purple with green spots and blotches. The general outline is a smooth, unbroken curve. The texture of a normal liver is firm. The excess bile does make the liver unfit for human food.", "51 10-0821: This inflamed liver in a young turkey is fibrotic and enlarged. The liver appears uniformly tan. The general outline is a smooth, unbroken curve. The texture of an enlarged, inflamed, fibrotic liver is hard. The fibrosis makes the liver unfit for human food. 10-0835: This inflamed liver in a young turkey contains large granuloma throughout. The liver appears purple with spots and blotches. The general outline is not a smooth, unbroken curve. The texture of an inflamed liver is soft to firm. The granuloma make the liver unfit for human food. The slight green tinge is suggestive of bile retention. 10-0866: The fat attached to the gizzard of this young turkey appears thin, pink, and transparent. This is compatible with wasting, which is a generalized disease condition. 10-0884: This inflamed liver in a young chicken is fibrotic and enlarged. The liver appears uniformly tan. The general outline is a smooth, unbroken curve. The texture of an enlarged, inflamed, fibrotic liver is hard. The fibrosis makes the liver unfit for human food. 10-0885: This normal liver in a young chicken contains excess fat. The liver appears tan with spots and blotches. The general outline is a smooth, unbroken curve. The texture of a fatty liver is soft. The excess fat does not make the liver unsafe or unfit for human food. 10-0907: This inflamed liver in a young chicken contains small granuloma throughout. The liver appears purple with spots and blotches. The general outline is a smooth, unbroken curve. The texture of an inflamed liver is soft to firm. The granuloma make the liver unfit for human food. The slight green tinge is suggestive of bile retention. 10-0923: Multiple black masses are visible in the liver and lung of this young chicken. Such masses are compatible with localized tumors and require trimming. 10-0929: This inflamed liver in a young chicken is fibrotic. The liver appears reddish-brown with spots and blotches. The general outline is not a smooth, unbroken curve. The texture of an inflamed, fibrotic liver is firm to hard. The fibrosis makes the liver unfit for human food. 10-0977: A clear, watery fluid is visible inside the

capsule surrounding the heart of young chicken. Such fluid retention is compatible with ascites. 10-0987: This inflamed heart in a young chicken evidences the presence of exudates in the sac around the heart and on the surface of the heart. The presence of exudates makes the heart unfit for human food. 10-0988: This inflamed heart in a young chicken evidences the presence of exudates in the sac around the heart and on the surface of the heart. The presence of exudates makes the heart unfit for human food. 10-0992: This inflamed heart in a young chicken evidences the presence of exudates on the surface of the heart. The presence of exudates makes the heart unfit for human food. 10-1039: This is a well-fleshed young chicken. A solitary mass is present in the skin. Such a mass is compatible with a localized tumor and require trimming. 10-1044: The normal thoracic air sac in this young chicken appears thin, pliable, and somewhat transparent. The minor quality defect \u2013 lung \u2013 does not make the carcass unsafe or unfit for human food. 10-1046: The normal thoracic air sac in this young chicken appears thin, pliable, and somewhat transparent. 10-1051: The abdominal air sac of this young chicken contains exudates, which evidence inflammation of the air sac and adjacent tissue. Inflamed tissue is unfit for human food.", "52 10-1052: The thoracic air sac of this young chicken contains exudates, which evidence inflammation of the air sac and adjacent tissue. Inflamed tissue is unfit for human food. 10-1054: The abdominal air sac and sac around the heart of this young chicken contain exudates, which evidence inflammation. The general outline of the liver is not a smooth, unbroken curve, which is suggestive of fibrosis. Inflamed tissue is unfit for human food. 10-1074: The abdominal air sac of this young chicken contains exudates, which evidence inflammation of the air sac and adjacent tissue. Inflamed tissue is unfit for human food. 10-1080: This is an adequately fleshed young chicken. Several , round, crater-shaped masses extend throughout the skin. Such masses are compatible with localized tumors and require trimming. 10-1100: This is a well-fleshed young chicken. Multiple, black masses are present in the skin. Such masses are compatible with localized tumors and require trimming. 10-1161: The skin of this young chicken appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The minor quality defects \u2013 red blemishes \u2013 do not make the skin unsafe or unfit for human food. 10-1203: A prominent greenish swelling is visible next to the kidney in this young chicken. The swelling and discoloration are consistent with the presence of exudates in the hip joint. Inflamed tissue is unfit for human food. 10-1232: This normal joint surface and tendon in a young turkey are white. The surface is shiny. 10-1254: The muscle tissue on this young turkey is mutilated. Mutilated tissue is contaminated and unfit for human food. 10-1257: This young turkey evidences inadequate body fat and normal skin. The prominent thighbone and uniformly dark muscle tissue are compatible with wasting, which is consistent with a generalized disease condition. 10-1318: This is an adequately nourished young turkey with adequate body fat and minimal blemishes. The body is slender. The general form of the wings and sternum is angular. The skin appears uniform in color, moist, and thin. The underlying muscle tissue is visible through the skin. 10-1320: This is a well-nourished young turkey with ample body fat and minimal blemishes. The body is plump. The general form of the wings and hips is round. The skin appears uniform in color, moist, and thick. The underlying muscle tissue is barely visible through the skin. 10-1324: This is a well-nourished young turkey with ample body fat and minimal blemishes. The body is plump. The general form of the wings and hips is round. The skin appears uniform in color, moist, and thick. The underlying muscle

tissue is barely visible through the skin. 10-1342: The upper drumstick from this young turkey is normal. The lower drumstick has a prominent swelling of the joint and the skin is thick and yellow. Such swelling and discoloration is consistent with the presence of exudates in the underlying tendons and skin. Inflamed tissue is unfit for human food. 10-1352: This young turkey evidences inadequate body fat and normal skin. The linear, red blemishes in the skin are veins filled with blood. The prominent thighbone and uniformly dark muscle tissue are compatible with wasting, which is consistent with a generalized disease condition." "53 10-1383: This is an adequately nourished young turkey with minimal quality defects \u2013 retained cuticle and surface blemishes. A prominent swelling is visible over the thighbone. Such swelling is consistent with the presence of exudates in the underlying tendons. Inflamed tissue is unfit for human food. 10-1424: The abdominal air sac of this young turkey contains exudates, which evidence inflammation of the air sac and adjacent tissue. Inflamed tissue is unfit for human food. 10-1465: This is a well-nourished young chicken with ample body fat and no obvious blemishes. The skin appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. 10-1490: This is a well-nourished young turkey with ample body fat and no obvious blemishes. The majority of the skin appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The thick, wet, yellow appearance of the skin over the breast is consistent with exudates and inflammation. 10-1502: The skin of this young turkey over the drumstick appears thick, wet, and yellow. The appearance of the skin is consistent with exudates and inflammation. 10-1532: The skin of this young turkey appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The minor quality defects \u2013 surface blemishes \u2013 do not make the skin unsafe or unfit for human food. 10-1544: This is an adequately fleshed young turkey with quality defects \u2013 surface blemishes. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The scabs and open sores with red margins are consistent with inflammation. 10-1568: This is an adequately fleshed young turkey with ample body fat and normal skin. The skin over the entire carcass is dark red. The red skin discoloration of the otherwise normal carcass is consistent with a bird that was still breathing when it entered the scald tank. 10-1606: The skin of this young turkey appears uniform in color, moist, and thick. Feather follicles appear uniform in size and arranged in rows with approximately equal space between follicles. The minor quality defects \u2013 retained cuticle and feather remnant \u2013 do not make the skin unsafe or unfit for human food. 10-1625: The skin of the hip in this young turkey is dark red. Such a discoloration is compatible with a bruise. Tissue affected by a bruise is unfit for human food. 10-1807: This normal liver in a young chicken appears reddish-purple with lights spots and blotches. The general outline is a smooth, unbroken curve. The texture of a normal liver is firm. The normal fat attached to the gizzard appears uniformly white and completely opaque. 10-1822: This is a well-nourished young chicken with ample body fat and no obvious blemishes. The body is plump. The general form of the wings and hips is round. The skin appears uniform in color, moist, and thick. The underlying muscle tissue is barely visible through the skin. 10-1846: This is an adequately nourished young chicken with adequate body fat and minimal blemishes. The body is slender. The general form of the wings and sternum is angular. The skin appears uniform in color, moist, and thin. The underlying muscle

Analysis and Critical Control Point (HACCP) plan or Sanitation Standard Operating Procedures (Sanitation SOP) or other prerequisite programs. The Agency is posting this guidance material on the FSIS Web site: <http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatory-compliance/compliance-guidesindex> and announcing its availability through the FSIS Constituent Update. This Compliance Guideline articulates how establishments can meet chilling requirements. It is important to note that this Guidance represents FSIS\u2019s current thinking on this topic and should be considered useable as of this issuance. Request for Comments FSIS is seeking comments on this guidance document. All interested persons may submit comments regarding any aspect of this document, including but not limited to: content, readability, applicability, and accessibility. FSIS will update these guidelines in response to any comments that it receives and as needed to reflect the most current information available to FSIS and stakeholders. The comment period will be 60 days.", "2 FSIS Compliance Guide: Modernization of Poultry Slaughter Inspection: Chilling Requirements 2014 Comments may be submitted by either of the following methods: Federal eRulemaking Portal: This Web site provides the ability to type short comments directly into the comment field on this Web page or attach a file for lengthier comments. Go to <http://www.regulations.gov> and follow the online instructions at that site for submitting comments. Mail, including CD-ROMs, and hand- or courier-delivered items: Send to Docket Clerk, U.S. Department of Agriculture, Food Safety and Inspection Service, Patriots Plaza 3, 1400 Independence Avenue, SW, Mailstop 3782, Room 8-163A, Washington, DC 20250-3700. Instructions: All items submitted by mail or electronic mail must include the Agency name, FSIS, and document title: FSIS Compliance Guideline for Chilling Requirements. Comments received will be made available for public inspection and posted without change, including any personal information, to <http://www.regulations.gov>. ", "3 FSIS Compliance Guide: Modernization of Poultry Slaughter Inspection: Chilling Requirements 2014 New Regulations Effective October 20, 2014 9 CFR 381.66 (b) (1) (i). Each official poultry slaughter establishment must ensure that all poultry carcasses, parts, and giblets are chilled immediately after slaughter operations so that there is no outgrowth of pathogens, unless such poultry is to be frozen or cooked immediately at the official establishment. 9 CFR 381.66(b) (1) (ii). Previously chilled poultry carcasses and major portions must be kept chilled so that there is no outgrowth of the pathogens, unless such poultry is to be packed and frozen immediately at the official establishment. 9 CFR 381.66(b) (2). After product has been chilled, the establishment must prevent the outgrowth of pathogens on the product as long as the product remains at the establishment. 9 CFR 381.66 (b) (3).The establishment must develop, implement, and maintain written procedures for chilling that address, at a minimum, the potential for pathogen outgrowth, the conditions affecting carcass chilling, and when its chilling process is completed. The establishment must incorporate these procedures into its HACCP plan, or sanitation SOP, or other prerequisite program. 9 CFR 381.66 (e) Air chilling is the method of chilling raw poultry carcasses and parts predominately with air. An antimicrobial intervention may be applied with water at the beginning of the chilling process, provided that its use does not result in any net pickup of water or moisture during the chilling process. The initial antimicrobial intervention may result in some temperature reduction of the product, provided that the majority of temperature removal is accomplished exclusively by chilled air.", "4 FSIS Compliance Guide: Modernization of Poultry Slaughter Inspection: Chilling Requirements 2014 Former Regulatory Provisions That Have Been Removed That May be

Followed to Meet New Requirements Establishments can meet the new chilling requirements by implementing the former regulatory time and temperature provisions that the final rule on modernization of poultry inspection removed from 9 CFR 381.66 (b). Below are the former regulatory provisions that an establishment can continue to implement to meet the regulatory requirements. FSIS considers these provisions to be \u201csafe harbors\u201d that will meet the new regulatory requirements. Under the new regulations, establishments producing RTC poultry that choose to use the former regulations must incorporate these procedures into their HACCP system (HACCP plan or Sanitation SOP or other prerequisite programs). These procedures will prevent the outgrowth of pathogens. As under any other procedures in a HACCP plan, Sanitation SOP, or other prerequisite program that is addressing pathogens, they will also need to continue to monitor those operating parameters and maintain documentation showing that they are following these procedures. Former provisions that FSIS considers to be safe harbors: A. All poultry that is slaughtered and eviscerated in the official establishment shall be chilled immediately after processing so that the internal temperature of poultry carcasses and major portions weighing under 4 pounds was reduced to 40 \u00b0F or below within 4 hours of processing; carcasses weighing 4 to 8 pounds, within 6 hours of processing; and those weighing over 8 pounds, within 8 hours of processing unless such poultry is to be frozen or cooked immediately at the official establishment. Once chilled, poultry to be packaged and shipped is to be stored at 40 \u00b0F or less. B. During further processing and packaging operations, the internal temperature of the poultry carcass may rise to 55 \u00b0F, provided that immediately after packaging, the poultry is chilled to 40 \u00b0F or placed in a freezer. Any poultry held at the establishment in packaged form longer than 24 hours should be held in a room at a temperature of 36 \u00b0F or lower. These times and temperatures ensure no bacterial outgrowth occurs before the package leaves the establishment. C. Only ice produced from potable water may be used for ice and water chilling, except that water and ice used for chilling may be reused in accordance with 9 CFR 416.2(g). Major portions of poultry carcasses (as defined in 9 CFR 381.170(b) (22) may be chilled in water and ice. The ice must also be handled and stored in a sanitary manner. D. Poultry chilling equipment must be operated in a manner consistent with meeting the applicable pathogen reduction performance standards for raw poultry products as set forth in 9 CFR 381.94 and the provisions of the establishment\u2019s HACCP plan.","5 FSIS Compliance Guide: Modernization of Poultry Slaughter Inspection: Chilling Requirements 2014 E. Previously chilled poultry carcasses and major portions must be maintained constantly at 40\u00b0 F or below until removed from vats or tanks for immediate packaging. Such products may be removed from the vats or tanks prior to being cooled to 40\u00b0 F or below, for freezing or cooling in the official establishment. Such products must not be packed until after they have chilled to 40\u00b0 F or below, except when the packaging will be followed immediately by freezing at the official establishment. F. Giblets should be chilled to 40\u00b0 F or lower within two hours of the time that they are removed from the inedible viscera, except that when the giblets are cooled with the carcass from which they were drawn, the giblets should be subject to the same time and temperatures for carcasses above in paragraphs A and B. Any of the acceptable methods of chilling the poultry carcass may be followed in cooling giblets. G. Poultry washing, chilling and draining practices and procedures must be such as will minimize water absorption and retention at time of packing. The establishment must provide scales, weights, identification devices and other

supplies necessary to conduct water tests. H. In air chilled, ready-to-cook poultry, the internal temperature of the carcasses shall be reduced to 40°F or less within 16 hours. Alternative Chilling Procedures Granted under Salmonella Initiative Program (SIP) waiver(s) Under the Modernization of Poultry Slaughter final rule, establishments will no longer need waivers of the regulatory provisions of 9 CFR 381.66 to use alternative approaches for chilling poultry.

Establishments that were granted SIP waivers from the time and temperature regulations can use the alternative chilling procedures to meet the new regulatory requirements. FSIS considers the alternative procedures approved under SIP waivers to be validated to prevent outgrowth of pathogens. The establishments producing RTC poultry that choose to use alternative operating parameters granted under SIP must incorporate these scientifically validated procedures into their HACCP system (HACCP plan or Sanitation SOP or other prerequisite programs). They will also need to continue to monitor those operating parameters. Below are examples of common alternative procedures implemented by establishments that participated in SIP. Because these alternative procedures have been validated under the SIP program, any establishment producing RTC poultry may choose to implement the alternative procedures and incorporate these scientifically validated procedures into their HACCP system (HACCP plan or Sanitation SOP or other prerequisite programs). These procedures will address the outgrowth of pathogens and no further scientific validation is needed. However, as with any procedure in a HACCP plan, Sanitation SOP, or other prerequisite program that addresses pathogens, establishments will need to document that they have executed these validated procedures to operate as intended within their establishment.", "6 FSIS Compliance Guide: Modernization of Poultry Slaughter Inspection: Chilling Requirements 2014 \u2022 Alternative procedures to chill young chicken carcasses immediately after processing so that the internal temperature is reduced to 44°F or below in six hours at the chiller exit. Under these alternative procedures, the internal temperature may rise to a maximum of 55°F during further processing provided that immediately after packaging the poultry is placed under refrigeration that promptly lowers the internal temperature to 44°F or less, and that temperature is maintained until shipping. Under these procedures, poultry held in packaged form in excess of 24 hours may be held in a room at a temperature of 40°F or less and poultry to be shipped from the establishment in packaged form needs to be maintained and shipped at 44°F internal temperature or less. \u2022 Procedures for time and temperature as the critical limit (CL) in the critical control point (CCP) to chill young chicken carcasses immediately after processing so that the internal temperature is reduced to 45°F or below in 16 hours. Under this alternative procedure, after chilling, the internal temperature may rise to a maximum of 60°F during further processing provided that immediately after packaging the poultry is placed under refrigeration that promptly lowers the internal temperature to 45°F or less until shipping. Under this procedure, poultry held in packaged form in excess of 24 hours needs to be held in a room at a temperature of 36°F, or less. \u2022 Procedures to maintain previously chilled young chicken carcasses and major portions so that the internal temperature is 44°F or below until removed from vats and tanks for immediate packaging. Such products may be removed from the vats or tanks prior to being cooled to 44°F or below for freezing or cooling in the official establishment. Under this alternative procedure, such products may not be packaged until after they have been chilled to 44°F or below, except when the packaging will be followed immediately by freezing at the official

establishment. \u2022 Procedures to chill giblets, major portions, paws, and parts to 44\u00b0F or less within 4 hours from the time they are removed from the inedible viscera."],{"file\_name":"FSIS\_GD\_2015\_0001","title":"Letter to Foreign Governments","num":"FSIS-GD-2015-0001","id":"60d5bcff3e9d342806310ea28e8399e581e720617cf67d34f4f5aaa3d5ad275c","corp\_us":"fsis\_guidelines","source\_page\_url":"https://www.fsis.usda.gov/policy/fsis-guidelines","url":"https://www.fsis.usda.gov/sites/default/files/import/Import-Rule-Letter-to-Foreign-Gov.pdf","type":"pdf","n\_pages":20,"word\_count":4916,"text\_by\_page":["USDA iiiiiii United States Department of Agriculture Food Safety and Inspection Service 1400 Independence Avenue, SW. Washington, D.C. 20250 TO: See Distribution SUBJECT: Final Rule-Electronic Import Inspection Application, Certification of Imported Products, Foreign Establishments; Amendments to PHIS, Other Import Inspection Regulations The U.S. Department of Agriculture's Food Safety and Inspection Service (FSIS) recently modified the meat, poultry, and egg products import regulations to allow foreign countries to certify shipments electronically, eliminating the need to issue a paper certificate. FSIS also modified its requirements for official inspection certificates to provide more flexibility to countries eligible to export products to the United States. Further, FSIS changed the annual certification of foreign establishments, and it clarified the U.S. prior notification requirements and the actions that FSIS will take when product for import is not presented for reinspection (FTP). On September 18, 2014, FSIS announced these changes in a final rule in the U.S. Federal Register (Docket No. FSIS-2009-0022; Electronic Import Inspection Application and Certification of Imported Products and Foreign Establishments: Public Health Information System and Import Inspection Regulations), and it notified the World Trade Organization of the rule as well (SPS\NV\USA\2484\Add.I). The final rule was effective on November 18, 2014; however, to ensure that foreign countries have sufficient time to adjust to the new requirements for certifying foreign establishments and additional product information on foreign inspection certificates, FSIS will allow countries to continue using existing inspection certificates until March 18, 2015. Foreign Establishment Certificates: FSIS will continue to require each eligible country's competent authority to submit annual certification of eligible establishments. FSIS sent a letter to each competent authority on December 16, 2014, requesting this certification; however, the December 16letter did not include the updated requirements that are contained in the final rule and discussed in Attachment 1 of this letter. Attachment 1 describes the changes designed to minimize the burden on foreign governments by reducing the information required for countries currently exporting to the United States that are not changing the previous year's annual establishment certification. Attachment 1 also includes the requirements for countries eligible to export to the United States that are changing the previous year's certification, or providing an initial certification. An Equal Opportunity Provider and Employer","Foreign Inspection Certificates: FSIS requires each eligible country's competent authority to certify shipments of product to the United States (9 CFR 327.4 (a) and (b), 381.197, and 590.915). After November 18, 2014, when foreign governments certify shipments electronically, FSIS no longer requires a paper copy of the certificate. You can find requirements for paper-based and electronic foreign inspection certificates in Attachment 2. Furthermore, FSIS has deleted certain requirements for the certification statements on foreign inspection certificates to provide foreign countries with

more flexibility. For paper-based foreign inspection certificates, the competent authority must certify that any product described on any official certificate is in compliance with requirements equivalent to U.S. domestic requirements. Foreign countries have the option to continue using the current certification statements or can certify to the applicable regulatory requirements (e.g. \u00a7327.2 (meat or meat products) or \u00a7381.196 (poultry or poultry products) or 590.910 (egg products)). Foreign governments can refer to the Codex Alimentarius generic model official certificate as a guideline for organizing the required data elements on an official certificate. The certificate guideline (CAC/GL 38-2001) can be found on the Codex Alimentarius Web site at: <http://www.codexalimentarius.org/standards/list-of-standards>. Questions about foreign inspection certificates should be submitted to FSIS at

InternationalEquivalence@fsis.usda.gov. Application for Import Inspection and Prior Notification: For foreign countries' awareness, FSIS also amended its regulations (9 CFR 327.5, 381.198, and 590.920) for the Import Inspection Application (FSIS Form 9540-1). These changes apply only to U.S. importers or brokers but could affect certified shipments destined for export to the United States if U.S. importers\brokers do not meet the requirements. U.S. importers and brokers have the option of submitting the application electronically through U.S. Customs and Border Protection's (CBP) Automated Commercial Environment (ACE) utilizing the Partner Government Agency (PGA) Message Set or on paper. FSIS will expand the PGA Message Set to include all ports, as well as all interested importers and brokers. For importers or brokers that electronically file entries with CBP using the PGA Message Set, this entry will replace the paper inspection application. U.S. importers or brokers that do not file the full PGA Message Set data must continue to submit paper applications to FSIS at the official import inspection establishment or other PSIS-approved location designated on the import inspection application. FSIS will enter the additional required FSIS data into the Public Health Information System (PHIS) Import Component by using information from the paper Import Inspection Application. An Equal Opportunity Provider and Employer","The final rule requires U.S. importers or brokers to submit electronic or paper import inspection applications to FSIS in advance of the shipment's arrival, but no later than when the initial entry is filed with CBP. If the U.S. importer or broker files the PGA Message Set with their Customs entry, this requirement is met. If the U.S. importer or broker is using the paper applications, this must be provided to FSIS in advance of the shipment's arrival at the official import inspection establishment (or other FSIS approved location designated on the import inspection application), and no later than when the entry is made with CBP. If the application has not been received prior to the shipment's arrival, FSIS will notify the establishment management of the violation, and that future shipments that do not meet the prior notification requirement may be refused entry. The objective of the prior notification requirement is to ensure that there is notice and data entry in PHIS is performed well before the shipment arrives at the official import inspection establishment. Importers and brokers that do not utilize PGA Message Set are to transition from the current FSIS Form 9540-1 to the revised Import Inspection Application (FSIS Form 9540-1) no later than March 18, 2015. Failure to Present (FTP): Imported meat, poultry, and egg products that have entered commerce without FSIS import reinspection violate the Federal Meat Inspection Act (21 U.S.C. 601-695); the Poultry Products Inspection Act (21 U.S.C. 451--472); or the Egg Products Inspection Act (21 U.S.C. 1031-1056), as well as the implementing regulations for each Act (9 CFR 327.6; 381.199; 590.925). It is the U.S. importer's responsibility to present the imported

product to FSIS, but there could be negative impact on the exporting company if the product enters commerce illegally (e.g., FSIS may request the importer of record conduct a voluntary recall of product in commerce). To help prevent future FTPs, FSIS will provide FTP notifications to the foreign competent authority. The foreign competent authority may then notify the exporter, as appropriate, to help ensure that future shipments will be presented to FSIS. An Equal Opportunity Provider and Employer", "While these regulatory changes provide for efficiencies at the port-of-entry, please be aware that FSIS will continue to require all shipments of meat, poultry, and egg products exported to the United States to be certified by the foreign country's competent authority and presented for reinspection at the designated FSIS official import inspection establishment or alternative inspection location authorized by FSIS. FSIS also will continue to perform verification activities at the designated official import inspection establishment on these imported products, prior to release into commerce. FSIS intends to work with foreign governments, industry, and all interested stakeholders in implementing these changes. In particular, we believe that progressing toward a more electronic environment will benefit the Agency, industry, and most of all, the public health. If you have questions, please contact Mike Kelley at Mike.Kelley@fsis.usda.gov or (713) 718-3322.

Incerel Daniel L. Engeljohn, PhD Assistant Administrator Office of Policy and Program Development An Equal Opportunity Provider and Employer", "Attachment 1: Foreign Establishment Certificate Requirements 1) Countries currently exporting to the United States that are making no changes to the previous year's annual establishment certification should submit the foreign establishment's name and control number (e.g. the establishment number assigned by the foreign inspection agency). The foreign official's title and signature is required for paper-copy submissions. FSIS does not require the foreign official's title and signature for foreign governments that electronically transmit foreign establishment certifications. 2) For countries providing an initial certification or countries currently exporting to the United States that are adding new establishments or listing any establishment for which information from last year's certificate has changed, the following information should be submitted for the new or changed establishments: \u2022 foreign establishment's name address, and control number; \u2022 foreign official's title, signature, and date (paper certificates only); \u2022 type of operations conducted at the foreign establishment (e.g., slaughter, processing, storage, exporting warehouse); \u2022 the establishment's eligibility status (e.g., new or relisted (if previously de listed) and, \u2022 for slaughter and processing establishments only, the species and type of products produced, such as the process category. The process categories include raw non-intact; raw -intact; thermally processed -commercially sterile; not heat treated -shelf stable; heat treated -shelf stable; fully cooked -not shelf stable; heat treated but not fully cooked -not shelf stable; and, products with secondary inhibitors -not shelf stable, and egg products.", "Attachment 2: Foreign Inspection Certificate Requirements 1) For paper-based foreign inspection certificates, FSIS requires the following information, in English, for all meat, poultry, and egg products: \u2022 date, name, and title of the official authorized to issue inspection certificates for products imported into the United States; \u2022 the official seal of the foreign government responsible for the inspection of the product; \u2022 foreign country of export and the producing foreign establishment number; \u2022 species used to produce the product and the source country and foreign establishment number, if the source materials originate from a country other than the exporting country; \u2022 product's description,

including the process category, the product category, and the product group (see Attachment 3); \u2022 name and address of the exporter or consignor; \u2022 name and address of the importer or consignee; \u2022 number of units (pieces or containers) and the shipping or identification mark on the units; \u2022 net weight of each lot, \u2022 production dates or codes used when country or establishment was ineligible. When production codes are used on product from establishments that have been delisted or relisted the codes must be translated into dates on the inspection certificate, and \u2022 any additional information needed by FSIS to determine whether the product is eligible to be imported into the United States., 2) For electronic foreign inspection certification, FSIS requires the same information listed above for paper-based certificates, except the name and title of the official authorized to issue inspection certificates for products imported into the United States.", "Attachment 3: Product Categorization FSIS has developed this document to assist with accurate identification of the meat, poultry, and egg products certified for export to the United States. Process Category: There are nine (9) process categories identified in 9CFR 417 .2(b ). Of the nine (9) listed, Slaughter is considered an internal process that occurs in establishments where the animals or birds are slaughtered. This category is not used for imported products. An additional process category that is not contained in 9CFR 417 .2(b ) is Egg Products. Note that FSIS has recently renamed two process categories: Raw Product-Ground and Raw ProductNot Ground are now referred to as Raw Product-Non-Intact and Raw Product-Intact, respectively. However, use of either terminology will be acceptable to FSIS. Note that official foreign inspection certificates should reflect the process category name, rather than the obsolete coding previously used by FSIS (e.g. 03B, 03C, etc.). These codes have been included in the table as some countries previously certified the process categories on the inspection certificates with this coding. Raw Product-Non-Intact: This process category applies to establishments that further process by using processing steps such as grinding, comminuting, injecting product with solutions, or mechanical tenderization by needling, cubing, pounding devices or other means of creating non-intact product. Examples of finished products in this category include raw products reconstructed into formed entrees, mechanically separated species and advanced meat recovery product. If the establishment produces bench trim or pieces of meat produced from non-intact meat, then the bench trim or pieces are also considered non-intact. Raw Product-Intact: FSIS considers raw products to be intact unless they have undergone any of the processes associated with the Raw Product-Non-Intact process category. Thermally Processed - Commercially Sterile: This process category applies to establishments that use a thermal processing step. Thermally processed, commercially sterile finished products are products in cans or flexible containers such as pouches, or semi-rigid, as in lunch bowls. Thermally processed, commercially sterile products are addressed in Subpart G, 318.300-311 for meat food products, and Subpart X, 381.300 to 311, for poultry products. Not Heat Treated-Shelf Stable: This process category applies to establishments that further process by curing, drying, or fermenting processing step as the sole means by which product achieves food safety. Establishments in this process category may apply a low-level heat treatment as long as the heat treatment is not used as means to achieve food safety. The finished products produced under this Process Categories are shelf stable. FSIS does not require shelf stable products to be frozen or refrigerated for food safety purposes. Heat Treated-Shelf Stable: This process category applies to establishments that further process by using a heat treatment processing

step to achieve food safety in combination with curing, drying, or fermenting processing step to achieve food safety. The finished products produced under this process category are shelf stable. FSIS does not require shelf stable products to be frozen or refrigerated for food safety purposes. If the establishment produces using the processing steps applicable under this process category,"and the product is not shelf stable, then establishment is producing product under the process category Fully Cooked-Not Shelf Stable. Fully Cooked-Not Shelf Stable: This process category applies to establishments that further process products by using primarily a full lethality heat process step (e.g. cooking) to achieve food safety. The finished products that establishments produce under this process category are not shelf stable. FSIS requires the products to be frozen or refrigerated for food safety purposes. These products also meet the definition of Ready to Eat (RTE) as defined in 9 CFR 430.1. Heat Treated but Not Fully Cooked-Not Shelf Stable: This process category applies to an establishment that further processes products that are (1) not ready-to-eat products (NRTE) or (2) raw otherwise processed products that are refrigerated or frozen throughout the product's shelf life. Meat and poultry products are produced using a heat process that meets one of the following criteria: a. The heat processing step is not adequate to achieve food safety. Products may be partially cooked or heated to set batter on a raw product. b. The heat processing step applied to meat or poultry component was adequate to achieve food safety, however product is further processed, assembled, or packaged so that cooked meat or poultry products contacts non-ready to-eat product ingredients. In this case, the final product is in a form that is not edible without additional preparing to achieve food safety. An example of this product is pot pie product that contains cooked chicken and raw dough. NOTE: This category may also include products that receive a full lethality treatment but there is no standard of identity defining them as fully cooked (e.g., hotdogs or barbecue) or a common or usual name that consumers understand to refer to RTE product (e.g., pates). Products with Secondary Inhibitors-Not Shelf Stable: This process category applies to establishments that further process by using a curing processing step or a processing step using other ingredients that inhibit bacterial growth. These products are generally refrigerated or frozen throughout the product's shelf life. Depending on the process and ingredients, these products may or may not meet the definition of RTE as defined in 9 CFR 430.1. Eggs\ /Egg Products: This process category applies to dried, pasteurized and unpasteurized egg products. Product Category (with Applicable Species) The Product Categories are shown in the PSIS Product Categorization table with the appropriate species indicated for each. The Species designations PSIS is using for PHIS are: for Meat: Beef, Veal, Pork, Lamb, Mutton, and Goat; for Poultry: Chicken, Turkey, Duck, Goose, Guinea, and Squab, including for Ratites: Emu, Ostrich, and Rhea; for Eggs: Chicken, Turkey, Duck, Goose and Guinea; and for Egg Products: Chicken, Turkey, Duck, Goose, and Guinea. For each product, the certification must indicate which species is predominant in the product to assure the appropriate regulations are applied to the product when applicable. Product Group. The product group defines the product down to a level that PSIS can program appropriate types of inspections (TOI) for examinations and laboratory sampling. Regulatory references are added where applicable for clarification. While these appear to be self-explanatory, for Raw Product-Intact, Cuts are cuts of meat (e.g., steaks, chops, etc.) that are below the Primal and Subprimal level."The following table displays the process categories and the types of finished products that can be present in a process category. Finished Product Types by Process Category

Raw Product NRTE Product RTE Products Thermally Processed Product Slaughter \u2022 Raw - Non Intact (Raw Ground) \u2022 Raw-Intact (Raw Not Ground) \u2022 Thermally Processed-Commercially Sterile \u2022 Not Heat-Treated -Shelf Stable \u2022 \u2022 Heat Treated -Shelf Stable \u2022 \u2022 Fully Cooked-Not Shelf Stable \u2022 Heat Treated but Not Fully CookedNot Shelf Stable \u2022 Product with Secondary Inhibitors-Not Shelf Stable \u2022 \u2022 \u2022 Eggs\Egg Products Not Applicable Ready to Eat applies to any product intended for human consumption without further preparation steps. Note: Products that appear fully cooked or are customarily consumed without further preparation, but the label does not include cooking instructions, are by default considered RTE. RTE fully cooked means that the products have been sufficiently cooked so that they are safe to eat as they are, with no further preparation required by the consumer. Note: Many of these products are customarily eaten hot, and heating instructions may be included on the label. Some frozen RTE products require reheating for palatability. These frozen products are still safe to eat without this further preparation by the consumer and are therefore still considered RTE. Some examples include: fully cooked hams, cooked beef, roast beef, pastrami, corned beef, hot dogs, meat loaves, meat and poultry salads, sliced luncheon meats, baked chicken, frozen entrees, and poultry rolls. Fresh or frozen entrees with fully cooked meat or poultry portions combined with fully cooked sauces, vegetables, pasta, or other ingredients are RTE products. These products are designed to be re-heated by the consumer, and may include instructions for re-heating. Not Ready to Eat applies to products with cooking instructions or labeled with statements on the principal display panel such as \"Cook Thoroughly, Cook and Serve, Not Ready to Eat, or For Safety and Quality-follow these cooking instructions.\" These products are considered NRTE. Certain NRTE products are required to bear safe handling instructions (SHI).,"Some NRTE finished products are heat treated but are not fully cooked. These NRTE products should have sufficient labeling information to inform the consumer that the product must be cooked for safety. This information may be contained within the product name on the principal display panel, and may contain cooking instructions that refer to cooking the product for safety rather than heating the product for best quality. The product often times may bear a safe handling instruction. Some NRTE finished products are prepared with both meat\poultry components that have received a lethality treatment in combination with non-meat\poultry components that need to receive a lethality treatment. These multi-component products, e.g., meals, dinners, and entrees, have labeling features which are conspicuous so that intended users are fully aware that the product must be cooked for safety. The principle display panel on the label defines these products, e.g., \"Cook and Serve, \"Must be thoroughly cooked,\" \"Cook before eating\", and the product should include cooking instructions when required. Processors should refer to <http://www.fsis.usda.gov/wps/wcmfcontent/ebb99ef17-40f9-4528-ac0f0b733ld871d6/ResourceI.pdf?MOD=AJPERES> for guidance on the labeling of NRTE products. ...","Raw Product-Non-Intact [HACCP] Process Category [Finished] Product Category Species Product Group Raw Product\u00ad Non-1 ntact Raw ground, comminuted, or otherwise non-intact beef Beef, Veal - Ground Beef [\u00a7319.1S(a)] -Hamburger [\u00a7319.15(b)] -Beef Patty Product [\u00a7319 .15(c)] -Formed Steaks [\u00a7319 .1S(d)] -Sausage [\u00a7319.142; 319.143] -Advanced Meat Recovery Product (AMR) -Finely Textured Beef -Non-1 nta ct Cuts -\u00b7 -Trimmings from Non-1 ntact -Bench Trim from Non-1 ntact -Other Non-Intact -Low Temperature Rendered Product -Partially Defatted Chopped Beef (PDCB) -Partially Defatted Beef Fatty Tissue

guidelines","url":"<https://www.fsis.usda.gov/sites/default/files/import/Import-Rule-Letter-to-Brokers.pdf>","type":"pdf","n\_pages":19,"word\_count":4852,"text\_by\_page":["USDA United States Department of Agriculture Food Safety and Inspection Service 1400 Independence Avenue, SW. Washington, D.C. 20250 Dear Importer or Customs Broker: The United States Department of Agriculture's (USDA) Food Safety and Inspection Service (PSIS) is the public health regulatory agency responsible for ensuring that domestic and imported meat, poultry, and processed egg products are safe, wholesome, and correctly labeled and packaged, based on the statutory authority of the Federal Meat Inspection Act (FMIA); the Poultry Products Inspection Act (PPIA); and the Egg Products Inspection Act (EPIA). All shipments of meat, poultry, and egg products exported to the United States, which are certified by the foreign country's competent authority, must be presented for reinspection at an PSIS official import inspection establishment, or alternative inspection location authorized by PSIS. FSIS has published a final rule that, effective November 18, 2014, changed FSIS' meat, poultry, and egg products import regulations to eliminate the requirement for a paper copy of the import application for import inspection (FSIS Form 9540-1), clarify that the prior notification timeframe for import inspection applications must be submitted when entry is filed with U.S. Customs and Border Protection (CBP) and change the specific product information that will assist FSIS in designating reinspection assignments and enforcement strategies for shipments that fail to present (FTP) to FSIS for reinspection. Additional clarification for each of these changes is provided below. Public Health Information System (PHIS) Import Component and the Automated Commercial Environment (ACE) On February 19, 2014, President Obama signed an Executive Order streamlining the import and export process for America's businesses. Executive Order 13659 requires the completion and government-wide utilization of the International Trade Data System (ITDS) by December 2016. When fully implemented, ITDS will allow businesses to submit the data required by CBP and its Partner Government Agencies (PGAs) to import or export cargo through the Automated Commercial Environment (ACE), or "Single Window." CBP is working to complete and deploy core trade processing capabilities in ACE by December 2016, and as part of this transition, a mandatory time line has been established requiring trade users to begin filing electronic data to ACE. Starting on November 1, 2015, importers or brokers must submit electronic cargo release and entry summary data-including any data within PGAs' jurisdiction-to CBP through ACE. An Equal Opportunity Provider and Employer,"The FSIS PHIS import component, which launched in 2012, automates and streamlines the import inspection application processes by electronically linking with CBP's ACE. The current PHIS-ACE interface accommodates a limited amount of data transfer, transmitting the entry and entry summary data collected by CBP. Importers and Customs brokers filing entry with CBP submit the additional PSIS-specific data on the paper import inspection application (FSIS Form 9540-1 ). Ultimately, the Single-Window system will enable U.S. importers and Customs brokers to enter FSIS import inspection application data directly into ACE through the Automated Broker Interface (ABI) as part of the CBP entry process, thereby eliminating the need to file a separate paper application with FSIS. To incorporate the PSIS-specific data elements as part of the PHIS-ACE interface and give importers or brokers the option of submitting import applications electronically, FSIS implemented a PGA Message Set pilot in April 2014, initially involving two Customs brokers and three ports of entry. The PGA Message Set populates additional PSIS-specific data elements in the PHIS import component for

importers and brokers filing entry with CBP, which expedites data entry and shipment clearance. Since the publication of FSIS' final rule, the PGA Message Set eliminates the need to file a separate paper application (FSIS Form 9540-1) with FSIS. FSIS will expand the pilot to include all ports, as well as all interested importers and brokers by November 2015. FSIS will soon provide information on upcoming stakeholder events that will give importers and brokers an overview of the FSIS PGA Message Set and outline the next steps for the industry. Import Inspection Application and Prior Notification FSIS' meat, poultry, and egg products import regulations require importers to apply for the inspection of imported product. In the final rule, FSIS clarified the timeframe for when applicants must submit import inspection applications; required the import inspection application (FSIS Form 9540-1) for egg products; and required additional information, such as production dates, when a country, foreign establishment, or specific product has been delisted or relisted as eligible for export. This information will help FSIS to verify that the relevant product was produced in the foreign establishment during an eligible timeframe. The final rule clarifies that applicants must submit import inspection applications to FSIS in advance of the shipment's arrival, but no later than when the initial entry is filed with CBP (prior notification). As noted above, the PHIS import component interfaces with CBP's ACE system and has the capability to receive the data needed to complete the import inspection application. Applicants that file their Customs entry with the PGA Message Set will meet the prior notification requirement. Applicants using paper applications must provide the paper application to FSIS in advance of the shipment's arrival at the official import inspection establishment or other PSIS-approved location designated on the import inspection application, and no later than when the entry is made An Equal Opportunity Provider and Employer", "with CBP. FSIS inspection program personnel will enter the additional required FSIS data into the PHIS import component by using information from the paper import inspection application. If FSIS has not received the application prior to the shipment's arrival, FSIS will notify the establishment management of the violation and that future shipments that do not meet the prior notification requirement will likely be refused entry. In addition, if the shipment is not rejected and FSIS proceeds with reinspection, the importer may experience delays in the import inspection process as a result of the delayed receipt of the application and subsequent data entry into PHIS. Importers and brokers that do not utilize PGA Message Set are to transition from the current FSIS Form 9540-1 to the revised import inspection application (FSIS Form 95401) no later than March 18, 2015. The revised FSIS Form 9540-1 ([http://www.fsis.usda.gov/wps/wcm/connect/a8eead0d-23c3-428e-937f\u00ad](http://www.fsis.usda.gov/wps/wcm/connect/a8eead0d-23c3-428e-937f/u00ad) a8a0Sb09edbb/FSIS~9540-1-Import-Inspection-Application.pdf?MOD=AJPERES) that is completed by the importer or broker must be correct. The revised import inspection application requires the production date(s) when a country, foreign establishment, or specific product has been de listed or relisted as eligible for export. If product codes are used in place of production dates, these codes must be translated into dates (mm\dd\yyyy) on the inspection certificate. Attachment 1 summarizes the options and requirements to apply for import inspection and Attachment 2 provides information on FSIS product categorization for meat, poultry, and egg products certified for export to the United States. Failure to Present (FTP) Imported meat, poultry, and egg product that has entered commerce without FSIS import reinspection violates the FMIA; the PPIA; or the EPIA, as well as the implementing regulations for each Act (9 CFR 327.6; 381.199; 590.925). The importer of record is responsible for any product identified as FTP

and when a product has been identified as a FTP, FSIS will request, through CBP, a redelivery of the shipment and appropriate CBP penalties. As part of the Single Window initiative, FSIS is working with CBP to automate the redelivery process by December 2016, which will streamline enforcement of CBP redelivery requirements and meet the goals of Executive Order 13659. Customs has full authority to assess penalties and liquidated damages claims and to seize merchandise for violations of Customs or other laws enforced by the Customs Service. For more information about CBP redelivery requirements and penalties, please contact CBP's Office of Regulations and Rulings (<http://www.cbp.gov/contact/internationaltrade-contacts>). FSIS may also request that the importer of record recall FTP product, if the shipment cannot be redelivered. Imported meat, poultry and egg products are considered "in-commerce" when they are off-loaded at a location other than the official import inspection establishment or other FSIS approved location designated on the import inspection application. If imported product bypasses FSIS reinspection, FSIS considers such product to be in-commerce and a FTP. The FTP product -whether the shipment is intact or partial -will no longer be eligible for reinspection. Product still in the original shipping containers may either be destroyed or returned to the country of An Equal Opportunity Provider and Employer", "origin. If any imported product identified as FTP has been removed from the original cartons or further processed, FSIS will initiate a regulatory control action to deal with the product, including any further processed product that contains the FTP product, to ensure appropriate disposition (i.e., destruction). Under this final rule, FSIS will continue to require all shipments of meat, poultry, and egg products exported to the United States to be certified by the foreign country's competent authority and presented for reinspection at the designated FSIS official import inspection establishment, or alternative inspection location authorized by FSIS. FSIS also will continue to perform verification activities at the designated official import inspection establishment on these imported products, prior to release into commerce. FSIS intends to work with foreign governments, industry, and all interested stakeholders in implementing these changes. In particular, we believe it is important for importers and brokers to begin adopting and participating in the electronic import processes described in this letter, which will help ensure that FSIS meets the goals and deadlines of Executive Order 13659. We believe this transition to a more electronic environment will benefit industry, FSIS, and most of all, the public health. FSIS strongly encourages importers and brokers to work together closely in meeting FSIS import requirements. If you have questions, please contact Mike Kelley at [Mike.Kelley@fsis.usda.gov](mailto:Mike.Kelley@fsis.usda.gov) or (713) 718-3322. Daniel L. Engeljohn, PhD Assistant Administrator Office of Policy and Program Development Enclosure An Equal Opportunity Provider and Employer", "Attachment 1: Options and Requirements for \u00b7 [Import Inspection Application Mode of CBP Entry Foreign Inspection Certificate Type Paper Foreign Inspection Certificate required? Process Category: There are nine (9) process categories identified in 9CFR 417.2(b). Of the nine (9) listed, Slaughter is considered an internal

process that occurs in establishments where the animals or birds are slaughtered. This category is not used for imported products. An additional process category that is not contained in 9CFR 417 .2(b) is Egg Products. Note that FSIS has recently renamed two process categories: Raw Product-Ground and Raw Product-Not Ground are now referred to as Raw Product-Non-Intact and Raw Product-Intact, respectively. However, use of either terminology will be acceptable to FSIS. Note that official foreign inspection certificates should reflect the process category name, rather than the obsolete coding previously used by FSIS (e.g. 03B, 03C, etc.). These codes have been included in the table as some countries previously certified the process categories on the inspection certificates with this coding.

**Raw Product-Non-Intact:** This process category applies to establishments that further process by using processing steps such as grinding, comminuting, injecting product with solutions, or mechanical tenderization by needling, cubing, pounding devices or other means of creating non-intact product. Examples of finished products in this category include raw products reconstructed into formed entrees, mechanically separated species and advanced meat recovery product. If the establishment produces bench trim or pieces of meat produced from non-intact meat, then the bench trim or pieces are also considered non-intact.

**Raw Product-Intact:** FSIS considers raw products to be intact unless they have undergone any of the processes associated with the Raw Product-Non-Intact process category.

**Thermally Processed -Commercially Sterile:** This process category applies to establishments that use a thermal processing step. Thermally processed, commercially sterile finished products are products in cans or flexible containers such as pouches, or semi-rigid, as in lunch bowls. Thermally processed, commercially sterile products are addressed in Subpart G, 318.300-311 for meat food products, and Subpart X, 381.300 to 311, for poultry products.

**Not Heat Treated-Shelf Stable:** This process category applies to establishments that further process by curing, drying, or fermenting processing step as the sole means by which product achieves food safety. Establishments in this process category may apply a low-level heat treatment as long as the heat treatment is not used as means to achieve food safety. The finished products produced under this Process Categories are shelf stable. FSIS does not require shelf stable products to be frozen or refrigerated for food safety purposes.

**Heat Treated -Shelf Stable:** This process category applies to establishments that further process by using a heat treatment processing step to achieve food safety in combination with curing, drying, or fermenting processing step to achieve food safety. The finished products produced under this process category are shelf stable. FSIS does not require shelf stable products to be frozen or refrigerated for food safety purposes. If the establishment produces using the processing steps applicable under this process category and the product is not shelf stable, then establishment is producing product under the process category Fully Cooked-Not Shelf Stable.

**Fully Cooked-Not Shelf Stable:** This process category applies to establishments that further process products by using primarily a full lethality heat process step (e.g. cooking) to achieve food safety. The finished products that establishments produce under this process category are not shelf stable. FSIS requires the products to be frozen or refrigerated for food safety purposes. These products also meet the definition of Ready to Eat (RTE) as defined in 9 CFR 430.1."

**"Heat Treated but Not Fully Cooked-Not Shelf Stable:** This process category applies to an establishment that further processes products that are (1) not ready-to-eat products (NRTE) or (2) raw otherwise processed products that are refrigerated or frozen throughout the product's shelf life. Meat and poultry products are produced using a heat process that meets one of the following

criteria: a. The heat processing step is not adequate to achieve food safety. Products may be partially cooked or heated to set batter on a raw product. b. The heat processing step applied to meat or poultry component was adequate to achieve food safety, however product is further processed, assembled, or packaged so that cooked meat or poultry products contacts nonready to-eat product ingredients. In this case, the final product is in a form that is not edible without additional preparing to achieve food safety. An example of this product is pot pie product that contains cooked chicken and raw dough. NOTE: This category may also include products that receive a full lethality treatment but there is no standard of identity defining them as fully cooked (e.g., hotdogs or barbecue) or a common or usual name that consumers understand to refer to RTE product (e.g., pates). Products with Secondary Inhibitors-Not Shelf Stable: This process category applies to establishments that further process by using a curing processing step or a processing step using other ingredients that inhibit bacterial growth. These products are generally refrigerated or frozen throughout the product's shelf life. Depending on the process and ingredients, these products may or may not meet the definition of RTE as defined in 9 CFR 430.1. Eggs\|Egg Products: This process category applies to dried, pasteurized and unpasteurized egg products. Product Category (with Applicable Species) The Product Categories are shown in the FSIS Product Categorization table with the appropriate species indicated for each. The Species designations FSIS is using for PHIS are: for Meat: Beef, Veal, Pork, Lamb, Mutton, and Goat; for Poultry: Chicken, Turkey, Duck, Goose, Guinea, and Squab, including for Ratites: Emu, Ostrich, and Rhea; for Eggs: Chicken, Turkey, Duck, Goose and Guinea; and for Egg Products: Chicken, Turkey, Duck, Goose, and Guinea. For each product, the certification must indicate which species is predominant in the product to assure the appropriate regulations are applied to the product when applicable. Product Group. The product group defines the product down to a level that FSIS can program appropriate types of inspections (TOI) for examinations and laboratory sampling. Regulatory references are added where applicable for clarification. While these appear to be self-explanatory, for Raw Product-Intact, Cuts are cuts of meat (e.g., steaks, chops, etc.) that are below the Primal and Subprimal level.", "The following table displays the process categories and the types of finished products that can be present in a process category. Finished Product Types by Process Category

Process Categories	Finished Products
Raw Product NRTE Product	RTE Products
Thermally Processed Product	Slaughter \u2022 Raw - Non Intact (Raw Ground) \u2022 Raw-Intact (Raw Not Ground) \u2022 Thermally Processed - Commercially Sterile \u2022 Not Heat-Treated-Shelf Stable \u2022 \u2022 Heat Treated -Shelf Stable \u2022 \u2022 Fully Cooked-Not Shelf Stable \u2022 Heat Treated but Not Fully CookedNot Shelf Stable \u2022 Product with Secondary Inhibitors-Not Shelf Stable \u2022 \u2022 Eggs\ Egg Products
Not Applicable Ready to Eat	applies to any product intended for human consumption without further preparation steps. Note: Products that appear fully cooked or are customarily consumed without further preparation, but the label does not include cooking instructions, are by default considered RTE. RTE fully cooked means that the products have been sufficiently cooked so that they are safe to eat as they are, with no further preparation required by the consumer. Note: Many of these products are customarily eaten hot, and heating instructions may be included on the label. Some frozen RTE products require reheating for palatability. These frozen products are still safe to eat without this further preparation by the consumer and are therefore still considered RTE. Some examples include: fully cooked hams, cooked beef, roast beef, pastrami, corned beef, hot dogs, meat loaves, meat

and poultry salads, sliced luncheon meats, baked chicken, frozen entrees, and poultry rolls. Fresh or frozen entrees with fully cooked meat or poultry portions combined with fully cooked sauces, vegetables, pasta, or other ingredients are RTE products. These products are designed to be re-heated by the consumer, and may include instructions for re-heating." "Not Ready to Eat applies to products with cooking instructions or labeled with statements on the principal display panel such as \"Cook Thoroughly, Cook and Serve, Not Ready to Eat, or For Safety and Quality-follow these cooking instructions.\" These products are considered NRTE. Certain NRTE products are required to bear safe handling instructions (SHI). Some NRTE finished products are heat treated but are not fully cooked. These NRTE products should have sufficient labeling information to inform the consumer that the product must be cooked for safety. This information may be contained within the product name on the principal display panel, and may contain cooking instructions that refer to cooking the product for safety rather than heating the product for best quality. The product often times may bear a safe handling instruction. Some NRTE finished products are prepared with both meat\poultry components that have received a lethality treatment in combination with non-meat\poultry components that need to receive a lethality treatment. These multicomponent products, e.g., meals, dinners, and entrees, have labeling features which are conspicuous so that intended users are fully aware that the product must be cooked for safety. The principle display panel on the label defines these products, e.g., \"Cook and Serve, \"Must be thoroughly cooked,\" \"Cook before eating\", and the product should include cooking instructions when required. Processors should refer to [http://www.fsis.usda.gov/wps/wcm/connect/ebb99e\\_17-40f9-4528-ac0f0b7331d871d6/Resource I.pdf?MOD=AJPERES](http://www.fsis.usda.gov/wps/wcm/connect/ebb99e_17-40f9-4528-ac0f0b7331d871d6/Resource I.pdf?MOD=AJPERES) for guidance on the labeling of NRTE products." State MPI program HACCP verification testing 3. State MPI program in-depth food safety reviews 4. State MPI program administrative enforcement actions IV. References and Attachments 1", "January 8, 2015 I. PURPOSE To provide guidance to State Cooperative Meat and Poultry Inspection (MPI) programs electing to use a data system other than FSIS\u2019s Public Health Information System (PHIS) for meeting the \u201cat least equal to\u201d data system essentials. II. BACKGROUND The Federal Meat Inspection Act (FMIA) (21 USC 661) and the Poultry Products Inspection Act (PPIA) (21 USC 454) provide for FSIS to cooperate with State agencies in

developing and administering their own Meat and Poultry Inspection Programs. Individual State MPI programs are required to operate in a manner and with authorities that are at least equal to the antemortem and post-mortem inspection, reinspection, sanitation, recordkeeping, and enforcement provisions as provided for in the FMIA and PPIA. Therefore, State MPI programs are required to develop a data system with characteristics that can produce inspection and recordkeeping outcomes at least equal to FSIS's procedures. FSIS maintains PHIS as its data system. PHIS functions as an integrated data collection and analysis system that verifies the effectiveness and efficiency of Agency inspection. FSIS relies heavily on data to promote proactive decisions affecting food safety and public health and has strengthened both its data collection and analysis activities to ensure valid, timely data is collected, carefully analyzed, and continually reported. FSIS ensures that data collected through PHIS is fully available and organized so that the analysis of data from FSIS's regulatory verification and compliance and enforcement activities, sampling, and other sources of data provide the Agency with evidence that shows whether or not the Agency's approach is working. To determine the success of the strategies used to combat threats to food safety and defense, FSIS employs data analysis as a management verification measure that helps ensure that the program components are effective in meeting the Agency's public health goals and objectives. FSIS recognizes that an integrated infrastructure with high quality data and feedback interaction is essential to a data-driven approach to inspection. A data-driven approach to inspection requires quality data collection methods, ongoing data analysis to refine analytical decisionmaking tools, and performance measures to assess the impact of policies and programs. PHIS is designed to consolidate and integrate the Agency's critical functions of inspection, surveillance, auditing, enforcement, scheduling, modeling, and analysis to provide better public health protection. It also reduces delays in FSIS decision-making by providing feedback loops that utilize the data input by the inspection staff and laboratory test results to drive automated scheduling functions, reporting functions, and alerting of events. PHIS uses the Task Library to develop the Task List for each establishment. Each task arrives on the inspection program personnel's (IPP) Task List with a due date and a frequency for performing the task. The inspectors then have the ability to place assigned tasks onto their personal Task Calendars and to schedule them for completion. PHIS gives IPP the flexibility to schedule tasks. As tasks are completed, IPP record their findings of compliance and non-compliance in PHIS. FSIS uses PHIS data to schedule follow-up tasks and additional lab sampling as required. There are feedback loops in PHIS that produce information vital to all levels of FSIS. Information and revised schedules are fed back to field personnel. Headquarters and District management generate reports to keep apprised of critical information for decision-making. Alerts and notifications are issued to Headquarters and IPP as events occur. The automated "January 8, 2015 feedback mechanisms are designed to reduce delays where action is required, through a system of specific input points. Alerts are issued when specific events requiring immediate attention occur. An alert consists of a trigger and a notification function. The trigger is a program that automatically scans the data for a specific event, and upon finding it, issues the notification. The notification can take the form of an email sent by PHIS, a message on the user's PHIS dashboard, or both. Examples of key events that would trigger an alert are: a large number of inspection activities not completed at an establishment, high rates of noncompliance in an

establishment, and a positive adulterant pathogen test result at an establishment (e.g., Escherichia coli (E. coli) O157:H7 in raw ground beef, Shiga toxin-producing Escherichia coli (STEC) in beef manufacturing trimmings, or Listeria monocytogenes (Lm)\Salmonella in ready-to-eat (RTE) products). The alert text gives directions to IPP by pointing them to the appropriate regulations and directives needed for the response. Reports are produced by PHIS that include aggregated data representing a period of time rather than a single specific event. Reports may be produced on demand and viewed online or offline. Reports allow users to access data and can be set up to flag irregular data so that users can investigate further and take corrective action. PHIS has a wide range of reporting capabilities and can produce a variety of reports. An example of a generated report is the monthly report of non-compliances by District. Reports are used at all levels of FSIS to manage the processes, to identify areas needing corrective actions, and to communicate progress towards goals.

III. ELEMENTS OF AN \u201cAT LEAST EQUAL TO\u201d DATA SYSTEM

To be \u201cat least equal to\u201d FSIS\u2019s system, the State MPI data system needs to:

- \u2022 Collect, analyze, and respond to establishment and State MPI program data
- \u2022 Monitor data streams to determine establishment performance, and
- \u2022 Respond, near real-time, to establishments that may pose a risk to public health

Also to be \u201cat least equal to,\u201d the State MPI data system needs to collect data from the following four activities:

1. Daily inspection verification activities at operating establishments
2. State MPI program HACCP verification testing
3. State MPI program in-depth food safety reviews
4. State MPI program administrative enforcement actions

Set out below are guidance and recommendations for State MPI programs on their data systems if they choose not to participate in PHIS. State MPI programs should monitor data collected from the four activities listed above. The data collected should be compared to different data sets (e.g., data of multiple circuits, data of multiple establishments, and data from previous months) and analyzed to determine whether the State MPI program is meeting program goals and objectives. State MPI programs should take appropriate actions, based on the analysis, when goals and objectives are not being met.

1. Daily inspection verification activities at operating establishments

Data Collection

State MPI programs should collect establishment demographics (profiles). These profiles should include critical up-to-date information about the establishment\u2019s size, products 3", "January 8, 2015 produced, production volume, recall history, non-compliance history, and food defense plans. HACCP information for the establishment should be available in the profile and include summary information, processing categories, food safety hazards, critical control points, and prerequisite programs. A State MPI program should ensure IPP verify that establishments\u2019 profile information is accurate and current at set intervals (e.g., at least every thirty days or whenever HACCP plans change).

NOTE: The FSIS PHIS Inspection Task Catalog is provided as an attachment to this guidance. This Task Catalog is subject to change, but it sets out the PHIS tasks available based on establishment profile information.

Data Analysis

The State MPI program\u2019s data system should contain public health-based decision criteria to identify establishments requiring more frequent inspection activities (e.g., increased directed food safety verification tasks). The State MPI program\u2019s data system should include a mechanism to react to inspection results. Examples of events or trends that would trigger the State MPI program to react to inspection results may include, but are not limited to:

- \u2022 A large number of inspection activities not completed in an establishment
- \u2022 High rates of non-compliance in an establishment

\u2022 A positive pathogen test result in an establishment (e.g., E. coli O157:H7 in raw ground beef or Lm in RTE products) \u2022 Infrequent establishment profile updates (e.g., HACCP plan changes failed to be identified or documented) \u2022 Tasks are not being performed at frequencies sufficient to ensure public health The State MPI programs should ensure data quality and accuracy (i.e., a system identifying outdated establishment profile information, unperformed tasks). 2. State MPI program HACCP verification testing Data Collection The State MPI programs should maintain a system for tracking pathogen and residue testing results. Data Analysis The State MPI program\u2019s verification testing system should contain public health-based decision criteria to identify establishments requiring more frequent inspection activities (e.g., increased directed sampling due to positive sampling results or concerns with establishment\u2019s production process). The system should include a mechanism to react to sampling results. Examples of events that would trigger the program to react to sampling results may include but are not limited to: \u2022 A large number of sampling activities not completed in an establishment \u2022 A large number of laboratory discards \u2022 Positive sampling results in an establishment for adulterant pathogens (e.g., E. coli O157:H7 in raw ground beef, STEC in beef manufacturing trimmings, or Lm/Salmonella in RTE products) 4", "January 8, 2015 \u2022 Violative residues \u2022 Identifying long term processes that may have exceeded their schedule (e.g., a Salmonella sample set that has not been finished) 3. State MPI program in-depth food safety reviews State MPI programs should have procedures (e.g., Food Safety Assessments (FSA)) in place to verify that an establishment\u2019s food safety systems are effective and producing wholesome unadulterated product. Data Collection A system should track routine and \u201cfor cause\u201d in-depth food safety reviews. Data Analysis The State MPI program\u2019s data system should include a mechanism to react to sampling and inspection results that could lead to a \u201cfor cause\u201d in-depth food safety system review. Examples of events that may trigger the State MPI program to conduct a \u201cfor cause\u201d in-depth food safety system review may include, but are not limited to: \u2022 Establishments not in compliance with specific laws and regulations \u2022 A positive for STECs in raw ground beef or raw ground beef components \u2022 A positive Lm or Salmonella in RTE products or a positive Lm food contact surface sample \u2022 A Class I recall or a food safety-related enforcement action (e.g., Notice of Intended Enforcement) that is not the result of an in-depth food safety system review \u2022 Establishments that fail Salmonella or Campylobacter performance standards \u2022 An establishment that is the supplier of product that tested positive for STECs in raw beef products \u2022 Human illness linked to product from a State-regulated establishment \u2022 An establishment that has a high level of public health-related Non-compliance Records (NR) 4. State MPI program administrative enforcement action State MPI programs should have procedures in place to initiate enforcement actions, as needed, to ensure food safety compliance. Data Collection The State MPI programs should maintain a system to collect data and facts to support administrative enforcement actions and to track the results of actions taken (e.g., NRs, in-depth food safety system reviews, intensified verification testing (IVT), suspensions, and recall information). Data Analysis The State MPI program\u2019s data system should include a mechanism to react to the data collected that support administrative enforcement actions. Examples of events that may trigger the State MPI program to take administrative enforcement actions may include, but are not limited to: \u2022 Positive STECs in raw ground beef or raw ground beef components

5","January 8, 2015 \u2022 Positive Lm, Salmonella, or E. coli O157:H7 in RTE products or a positive Lm food contact surface sample \u2022 An establishment which is the supplier of product that tested positive for STECs in raw beef products \u2022 Human illness linked to State-regulated product from an establishment (possible recall) \u2022 Establishments not in compliance with specific State laws and regulations An explanation of the data system and supporting documents are to be included in the annual State Self-Assessment that is submitted to the Federal State Audit Branch by November 15. Verify the establishment reassessed the plan if a deviation not covered by a corrective action occurred, or another unforeseen hazard arose; if a raw meat or raw poultry product tested positive for Salmonella at a rate exceeding performance standard on the second consecutive series of FSIS tests; or if there was a change that could affect the hazard analysis or alter a HACCP plan. If plan reassessment revealed a HACCP plan no longer meets \u00a7417.2(c) requirements, the establishment modified the HACCP plan. Individual who performed plan assessment or modification meets the training requirements. Verify establishment records document the decision making associated with the selection and development of CCPs and critical limits, and support the monitoring and verification procedures and frequency; document slaughter product a shipment of product, product code, product name or other identifier. Verify each record entry is made when the time specific event occurs, and includes date and time recorded, and is signed or initialed by the employee who made entry. Verify the establishment has implemented controls to ensure data integrity for plant records maintained on computers. Verify \u00a7417.5(a)(3) requires HACCP records be maintained for at least 1 year for slaughter activities and refrigerated product and 2 years for frozen, preserved, or shelfstable product; on site for at least six months, and are made available to inspection program personnel within 24 hours of request if stored off site. Verify each record entry is made at the time when the event occurs, and includes date and time and is signed or initialed by the employee who made entry. Prior to shipping a product for distribution, the establishment conducts a review of associated records including a determination that all critical limits were met, and when appropriate, a determination that the establishment took corrective action(s), including proper disposition of product. 03J03 Priority 3: Livestock Zero Tolerance Verification Verification of zero tolerance for feces, milk, ingesta on livestock carcasses Verify the adequacy of the establishment\u2019s procedures to ensure that carcasses are not contaminated with fecal material, ingesta, or milk by the post-mortem rail inspection 22","January 8, 2015 Inspection Task Code, Priority Task Name, Reg\Directive Inspection Task Description and Verification 9 CFR 307.2(g) and (m), \u00a7310.3, \u00a7310.17a,

\u00a7310.18a, \u00a7318.4b, \u00a7381.65e and \u00a7381.76(b)(iv) FSIS Directives 5000.1 and 6420.2 station, and that head, cheek, and weasand meat are not contaminated with fecal material, ingesta, or milk at the completion of the harvesting process 03J04 Priority 3: Poultry Zero Tolerance Verification 9 CFR 307.2(g) and (m), \u00a7310.3, \u00a7310.17a, \u00a7310.18a, \u00a7318.4b, \u00a7381.65e and \u00a7381.76(b)(iv) FSIS Directives 5000.1 and 6420.2 Verification of zero tolerance for feces on poultry carcasses entering chilling system Verify that the establishment\u2019s process is producing carcasses free of visible fecal material 04A01 Priority 6: Percent Yield\Shrink 9 CFR 319.107 \u00a7319.80 \u00a7319.81 \u00a7319.100 \u00a7319.101 \u00a7319.102 \u00a7319.103 \u00a7319.106 \u00a7424.21 (c) FSIS Directive 7620.3 \u201cProcessing Inspectors\u2019 Calculations Handbook\u201d Chapters 11, 12, & 13; % gain, %shrink & %yield Verification of certain products that have a specified %Yield\Shrink as part of their Standard of Identity are met and not misbranded. Select an appropriate product and Verify compliance with regulatory requirements by reviewing establishment records and labels, calculating the % yield or shrink, and comparing the result with the appropriate regulatory requirement. In addition, Verify compliance by weighing a sample of product before and after the appropriate step in the process calculating the % yield or shrink, and comparing the result with the appropriate regulatory requirement. 04A02 Priority 6: X Percent (%) Solution 9 CFR \u00a7319.104\* \u00a7319.105\* \u00a7381.129 \u00a7381.169 \u00a7317.2 (c) \u00a7317.8 \*NOTE: Applies only to sections of 319.104 and 319.105 covering X% labeled products. FSIS Directives 7620.3 Chapter 10 Verification of products that contain Percent (%) Added Solution meets regulatory standards and are not misbranded. \*NOTE: Applies only to X% Labeled Products Select an appropriate product and Verify compliance with X% labeling requirements by reviewing establishment records and labels, calculating the % added solution and comparing the results with the X% labeling declaration. In addition, inspection program personnel are to Verify compliance by weighing a sample of product before and after the appropriate step in the process (i.e., pumping, curing, drying, etc.), calculating the % added solution, and comparing the result with the X% labeling declaration. 23", "January 8, 2015 Inspection Task Code, Priority Task Name, Reg\Directive Inspection Task Description and Verification Labeling Policy Book FLD Policy Memos 42 44A 57A 59 66C 84A 04A03 Priority 6: MSS; MSP; PDBFT; PDPFT; PDCB; PDCP; AMRS 9 CFR 318.24 \u00a7319.5 \u00a7319.15(e) \u00a7319.29 \u00a7381.173 FSIS Directives 7160.1 7160.2 7160.3 Revision 1 Verification of Mechanically Separated, Partially Defatted, and Advanced Meat Recovery Products meet regulatory requirements. Select an appropriate product and Verify compliance by reviewing establishment records and labels, or by observing the preparation of products, and comparing the findings to the standards listed in the regulations. In addition, inspection program personnel are to take samples as directed. To Verify compliance, inspection program personnel should: -check product identification, condition, temperature, and holding time\temperature. -examine bones (for example, two intact portions of bones) before and after the meat recovery systems in order to observe condition and conformation. -review establishment laboratory results and compare findings with the appropriate regulatory standard -take samples as directed. 04A04 Priority 6: Batter Breading 9 CFR 319.880 \u00a7381.166 FSIS Directive 7620.3 Chapter 14 Directive 7220.1 Labeling Policy Book FLD Policy Memo 089 Verification of batter and breading of applicable products meets regulatory requirements and product is not misbranded. Select an appropriate product, Verify

compliance with the batter and breading regulatory requirements by reviewing establishment records to calculate final % batter\breading, and comparing the findings to the standards listed in the regulations. In addition, inspection program personnel are to: Verify compliance by performing batter and breading pickup tests on one or more subgroups (according to the plant\u2019s QC programs) or batches of the product. 04A05 Priority 6: Livestock Finished Product Standards Verification of Livestock products are wholesome and not adulterated. 04A06 Priority 6: Poultry Finished Product Standards Verification of poultry products are produced in a safe, wholesome manner and not misbranded. 04B01 Priority 6: Labeling - Product Standards 9 CFR 319.15 \u00a7319.140 \u00a7319.141 \u00a7319.142 \u00a7319.143 \u00a7319.144 \u00a7319.145 \u00a7319.160 \u00a7319.180 \u00a7319.181 \u00a7319.182 \u00a7319.260 \u00a7319.261 \u00a7319.280 \u00a7319.281 \u00a7319.300 \u00a7319.301 \u00a7319.302 \u00a7319.303 \u00a7319.304 \u00a7319.305 \u00a7319.306 Verification of Product Labeling Standards Select an appropriate product and Verify compliance by reviewing establishment records and labels; or observe the preparation of products and compare the findings to the appropriate regulatory standards. Verify some regulatory requirements, by performing calculations to determine specified components, such as % fat, or % water.

24", "January 8, 2015 Inspection Task Code, Priority Task Name, Reg\Directive Inspection Task Description and Verification \u00a7319.307 \u00a7319.308 \u00a7319.309 \u00a7319.310 FSIS Directives 7620.3 7220.1 04B02 Priority 6: Child Nutrition\Grade Labeling\ Declared Count\Vignette A 9 CFR 317.2, \u00a7317.8 and \u00a7381.116 FSIS Directives 6810.1 and 7222.1 Verification of Child Nutrition Labeling Select product and Verify that the product\u2019s label is correct and a label approval is on file 04B03 Priority 6: Labeling - Net Weights 9 CFR 317.18, \u00a7317.19 \u00a7317.20, \u00a7317.21, \u00a7317.22, \u00a7381.121a, \u00a7381.121b, \u00a7381.121c, \u00a7381.121d, and \u00a7381.121e NBS Handbook 133 NIST Handbook 44 Verification of Net Weights Select an appropriate retail-sized product and Verify net weight regulatory requirements by reviewing establishment records and conducting net weight\drained weight, scale calibration, or tare weight checks. Follow the QC program requirements after evaluating the program to ensure that following the program results in compliance with net weight regulatory requirements. \* FSIS has determined inspectors are to use NBS handbook 133 and NIST Handbook 44 as the definitive references for determinations of net weight compliance. 04B04 Priority 6: General Labeling 9 CFR Part 316 Part317 Part 318 Part 319 \u00a7319.6 \u00a7327.10(d) \u00a7327.26 Part 381 \u00a7381.174 \u00a7424.21 \u00a7441.10 FSIS Directives 7120.1, 7620.3, 6700.1, 7235.1 and 7270.1 Verification of General Labeling Requirements Verify that: 1) the label contains all required information; 2)the ingredients statement is accurate, (i.e., that all ingredients are listed in descending order of predominance); 3) the label declares any proteinaceous substances\* used in the ingredients statement; 4) the establishment used restricted ingredients as per regulatory requirements; 5) the label is used on appropriate product; and a label approval is on file. Verify the establishment meets the regulatory requirements for pre-stamping of imported product. When verifying restricted ingredient requirements or ingredient statement compliance, inspection program personnel are to observe the establishment formulating product and compare to the approved label. \* NOTE: Proteinaceous substances can cause adverse reactions (i.e., allergic and nonallergic) in certain individuals, and therefore, such substances are of a food safety concern if not clearly declared in the ingredients statement. 04C02 Priority 6: Livestock

Humane Handling 9 CFR 313, \u00a7318.2, \u00a7318.5, \u00a7318.6, \u00a7500.1, Verification of compliance with the following categories: \uf0fc adequate measures for inclement weather \uf0fc truck unloading \uf0fc water and feed availability \uf0fc handling during ante-mortem inspection \uf0fc handling of suspect and disabled animals 25", "January 8, 2015 Inspection Task Code, Priority Task Name, Reg\Directive Inspection Task Description and Verification \u00a7500.2, and \u00a7500.3 FSIS Directive 6900.1 and 6900.2 \uf0fc electric prod\alternative object use \uf0fc observations for slips and falls \uf0fc stunning effectiveness \uf0fc check for conscious animals on the rail \uf0fc check for sensibility NOTE: Humane handling is not, never has been, and never will be a HACCP issue. To verify compliance, inspection program personnel are to select and process samples and mail to the designated laboratory as scheduled, or when there is reason to believe that product does not comply with regulatory requirements. Food Safety\Public Health Directed Sampling Economic Testing and Criteria verify compliance by collecting, processing and mailing samples (bacon, species testing, Escherichia coli 0157:H7, Salmonella, Listeria, advanced meat recovery products, mechanically-separated species, etc.) to the designated laboratory, upon request from computer-generated instructions, or upon instructions from the Frontline Supervisor or District Office, or Washington Headquarters. 05C01 Directed Residue Sampling Verification of Task for directed residue sampling for NRP Residue Sampling 26", "January 8, 2015 Inspection Task Code, Priority Task Name, Reg\Directive Inspection Task Description and Verification 9CFR 310.21, \u00a7381.9 \u00a7381.80, and \u00a7381.346 FSIS Directives 7355.1 10,210.1 10,220.1 Residue Sampling and Criteria Collect random samples of poultry and livestock as requested for monitoring, and surveillance samples (KIS), or submit diagnostic samples as necessary Prepare sample and mail designated laboratory. Perform in-plant residue testing on livestock as required. 06B01 Priority 5: Custom Exempt 9CFR 303.1, \u00a7316.6, \u00a7317.6, \u00a7320.1, \u00a7381.10 \u00a7381.14, \u00a7381.15 and \u00a7381.175 FSIS Directive 5930.1 Verify that custom exempt operations in official establishments meet regulatory

requirements and do not impact inspected products or operations. . Custom Exempt\Retail Exempt Verify the establishment is conducting custom-exempt\retail-exempt operations in accordance with all applicable regulatory requirements including time\space separation and adequate procedures to assure that product does not bear the mark of inspection. . Actions are taken by the establishment or FSIS determines that the standards have not been met. This includes actions to ensure that misbranded\mislabelled products do not enter commerce.

06B02 Priority 5: Retail Exempt Verify that retail exempt operations do not interfere with inspected products\operations 06D02 Priority 3: Other Inspection Requirements 9CFR 307.2, \u00a7308.3 \u00a7308.8, \u00a7310.1, \u00a7310.3 \u00a7381.36, \u00a7381.76, \u00a7416.15, \u00a7416.17(c)&(d), \u00a7381 and Subpart H \u00a7381.50(a)(f) \u00a7381.91 FSIS Directives 5000.1, 5220.1 Rev.1, 5930.1, and 7640.1 Verify other inspection requirements Facilities and Equipment Verify plant facilities (including lighting, ventilation, and plumbing) and equipment meet regulatory requirements and therefore do not pose a public health hazard or result in product contamination. Verify welfare areas and lockers are clean. Verify outside premises are clean and orderly. Verify actions are taken by the establishment or FSIS determines that the standards have not been met. This includes actions to ensure that misbranded\mislabelled products do not enter commerce. Other Requirements Verify inspection and Reprocessing Stations meet the criteria set forth in regulations to ensure they are adequate for the purpose and do not pose a public health hazard. Verify that line speeds do not exceed regulatory limits. Verify that efficient inspection can be performed on carcasses and parts Verify actions are taken by the establishment or FSIS determines that the standards have not been met. This includes actions to ensure that misbranded\mislabelled products do not enter commerce. 07B01 Update Establishment Profile Review and update establishment profile to reflect current establishment operations. 07C01 Meeting with Establishment Management FSIS Directive 5420.6 Meet with establishment management for food defense surveys 08A11 Priority 6: 2011 Food Defense Survey Record performance of 2011 Food defense survey (note only some establishments in PHIS at this point) 27", "January 8, 2015 Inspection Task Code, Priority Task Name, Reg\Directive Inspection Task Description and Verification 08S14 Priority 6: Food Defense - Water Systems FSIS Directive 5420.6 Verify establishment measures to protect water systems (a) observe the security of the establishment\u2019s water systems, especially well water, ice storage facilities, and water reuse systems; (b) pay special attention to water used to prepare injection solutions and water and ice used in emulsification (for the production of deli meats and hot dogs); (c) to a lesser extent, check water used to prepare surfactant, antimicrobial agent sprays, and chill tank recharge. Suggested Activities: Determine whether the establishment: controls access to private wells; appropriately secures potable water lines or storage tanks; appropriately secures ice storage facilities. 08S15 Priority 6: Food Defense \u2013 Processing Manufacturing FSIS Directive 5420.6 Verify food defense for processing and manufacturing areas (a) observe production processes (e.g., raw product handling, processing, and packaging of final product) in which exposed products are being handled for indications of attempts to introduce contaminants into the product; (b) observe, in particular, operations where the establishment mixes bulk products (e.g., process monitoring by establishment personnel at balance tanks, grinding\emulsification of meat and poultry products, solution injection in preparation areas); (c) observe whether the establishment has procedures in place to prevent deliberate contamination (e.g., camera surveillance, closed

systems, or restricted access of personnel to sensitive production areas). Suggested Activities: Check a production process (e.g., ground beef production area) for evidence of possible intentional product contamination. Check to determine whether the establishment has implemented a system to restrict access to sensitive processing areas where bulk products are mixed or processed (e.g., camera surveillance, color-coded uniforms, identification badges, sign-out sheets). Check calibration of equipment (if any) used to dispense restricted ingredients.

08S16 Priority 6: Food Defense - Storage Areas FSIS Directive 5420.6 Verify access\tampering in storage areas. (a) observe products in cold and dry storage areas for evidence of tampering; (b) pay special attention to bulk product ingredients that will undergo mixing, such as combo bins of meat trim and poultry parts used for grinding or emulsification; (c) check dry ingredients, including spices, breading materials, and those used in injection solution preparations, for indication of tampering; (d) observe the use and storage of any hazardous materials in the establishment; (e) verify whether entry into such storage areas is controlled, and that usage logs are maintained and current; (f) pay special attention to cleaning materials, particularly those used in clean-in-place systems; (g) pay special attention to areas where bulk products are mixed (e.g., storage silos); and (h) verify the control of laboratory reagents and cultures.

Suggested Activities: Verify that the establishment has implemented: access control procedures to dry ingredient areas; access control procedures to raw product storage areas; access control procedures to finished product storage areas; control procedures for access and use of hazardous chemicals; and 28", "January 8, 2015 Inspection Task Code, Priority Task Name, Reg\Directive Inspection Task Description and Verification observation procedures of all products in storage for evidence of tampering.

08S17 Priority 6: Food Defense - Shipping and Receiving FSIS Directive 5420.6 Verify food defense in shipping and receiving areas (a) observe loading dock areas and vehicular traffic in and out of the establishment; (b) report immediately all unattended deliveries on loading docks and unmarked vehicles parked on the premises to establishment management; (c) verify that the establishment secures, when possible, dry and cold products stored in on-site trailers and parks the trailers in a restricted access area of the facility; (d) verify that the facility security staff routinely check the trailers\u2019 physical integrity (e.g., locks, seals, and general condition); and (e) pay special attention to storage silos, combo bins of meat trim, and dry ingredients.

Suggested Activities: Check to determine whether the establishment has procedures in place to restrict or control access to the loading dock area and verify that the establishment has implemented these access control procedures. Observe incoming raw materials to verify that the establishment checks deliveries against shipping documents. Pay special attention to tanker trucks, dry ingredients, combo bins of fresh meat trim or poultry parts, and boxes of frozen trim that the establishment will ship for further processing.

08S19 Priority 6: Food Defense - Processing; Manufacturing FSIS Directive 5420.6 Food defense verification in processing and manufacturing areas for ID warehouses

08S20 Priority 6: Food Defense - Storage Areas FSIS Directive 5420.6 Verify food defense in storage areas in ID warehouses.

08S21 Priority 6: Food Defense - Shipping and Receiving (V) FSIS Directive 5420.6 Verify food defense for shipping and receiving in ID warehouses.

Before submitting label applications for approval, establishments should ensure that the print is legible and that all required features (i.e., inspection legend, ingredients statement, handling statement, product name, signature line, and safe handling instructions, net weight, and nutrition facts, when required) are present and in compliance with requirements. The generic approval labeling regulations (9 CFR 412.2) provide for use of final labeling without further authorization from FSIS. It is the establishment's responsibility to prepare final labeling in accordance with applicable regulations\policies, and to create and maintain records of all final labeling. Establishment Responsibility \u2022 Create a record of final labeling for labeling previously approved as a sketch by LPDS. Final labeling includes modifications made by LPDS during evaluation. \u2022 Create a record of final labeling that has been generically approved. \u2022 Create a record of final labeling when changes are made to a label that do not require LPDS reapproval (changes that do not affect any special statements or claims and are in compliance with all regulations; adding additional products to a blanket label approval) \u2022 Update labeling records with temporary approvals where regulatory deviations occur that have received temporary approval from LPDS. \u2022 Maintain labeling records and provide them for FSIS inspectors upon request. Label Record Each label record consists of: \u2022 The actual product's label \u2022 The product formulation \u2022 Processing procedure \u2022 All documentation required to demonstrate the label\u2019s compliance with regulatory requirements, including sketch or temporary approvals if appropriate. For additional information, please contact LPDS at (301) 504-0878."]}, {"file\_name": "FSIS\_GD\_2015\_0006", "title": "Prior Notification and Failure to Present: Compliance Guidance for Importing Meat, Poultry and Egg Products to the United States", "num": "FSIS-GD-2015-0006", "id": "83ca372c7def62c7b31861d9573d790e12266b735cce6be6158303c08f3a38c0", "corpus": "fsis\_guidelines", "source\_page\_url": "<https://www.fsis.usda.gov/policy/fsis-guidelines>", "url": "<https://www.fsis.usda.gov/sites/default/files/import/failure-to-present.pdf>", "type": "pdf", "n\_pages": 5, "word\_count": 1998, "text\_by\_page": ["Prior Notification and Failure to Present: Compliance Guidance for Importing Meat, Poultry and Egg Products to the United States This guidance is designed to help importers of record (IOR), U.S. Customs brokers, and Official Import Inspection Establishment management understand and comply with the Food Safety and Inspection Service\u2019s (FSIS) import inspection regulations for meat, poultry, and egg products on prior notification and explains regulatory actions taken when products fail to present for FSIS reinspection, known as \u201cFailure to Present\u201d (FTP). Background: Final Rule and Statutory Authority FSIS published a final rule, effective November 18, 2014, that amends the meat, poultry, and egg products import regulations to provide for the Agency\u2019s Public Health Information System (PHIS) Import Component. The final rule also clarifies prior notification requirements and the definition of FTP for imported product, among other changes. The regulatory changes in this rule are based on the statutory authority of the Federal Meat Inspection Act (FMIA) (21 U.S.C. 601\u2013695); the Poultry Products Inspection Act (PPIA) (21 U.S.C. 451\u2013470); and the Egg Products Inspection Act (EPIA) (21 U.S.C. 1031\u20131056). This guidance discusses and clarifies FSIS"]}]

prior notification and FTP requirements as described in the final rule. Definitions For the purposes of this guidance, electronic applications are applications for import inspection that are submitted through the Partner Government Agency (PGA) Message Set, which facilitates the transfer of required FSIS-specific data from the U.S. Customs and Border Protection (CBP) Automated Commercial Environment (ACE) into FSIS Public Health Information System (PHIS). Paper applications are FSIS Form 9540-1, Import Inspection Application. Applying for import inspection electronically (i.e. PGA Message Set) eliminates the need to file a separate paper application with FSIS. Prior Notification of Imported Product The final rule clarifies that the applicant (importer of record or designated agent) must apply for the inspection of imported product as far as possible in advance of the anticipated arrival of each consignment, but no later than when entry is filed with CBP (9 CFR 327.5(b), 381.198(b), and 590.920(b)). The objective of the prior notification requirement is to enhance FSIS ability to identify shipments that are not presented for inspection, as well as to ensure that there is notice and data entry in PHIS is performed well before the shipment arrives at the official import inspection establishment, thus avoiding delays in the re-inspection of the shipment by FSIS at the official import inspection establishment. It is important to emphasize that applicants automatically meet the prior notice requirement by filing Customs entry with the PGA Message Set (i.e., an electronic application). Applicants using paper applications will meet the prior notice requirement if the application is provided to FSIS at the official import inspection establishment (or other FSIS approved location designated on the import inspection", "application) as early as possible, but no later than when entry is filed with CBP). Of note, FSIS has revised the import inspection application (FSIS Form 9540-1) to include egg products and additional required information, such as production dates, and whether and when a country, foreign establishment, or specific product has been delisted or relisted as eligible for export. This information will help FSIS to verify that the relevant product was produced in the foreign establishment during an eligible timeframe. FSIS announced in the final rule that importers and brokers that do not use the PGA Message Set are to transition from the current FSIS Form 9540-1 (Import Inspection Application and Report) to the revised FSIS Form 9540-1 (Import Inspection Application) no later than March 18, 2015. The revised FSIS Form 9540-1 completed by the importer or broker must be correct. Table 1: Options and Requirements for Import Inspection Application Mode of CBP Entry Foreign Inspection Certificate Type Paper Foreign Inspection Certificate required? Paper 9540-1 required? Prior notification met? ACE\Automated Commercial System (ACS) Entry Paper Yes Yes Yes, if paper 9540-1 received no later than when entry filed with CBP ACE\ACS Entry Electronic certification (eCert) No Yes Yes, if paper 9540-1 received no later than when entry filed with CBP ACE with PGA Message Set Paper Yes No Yes ACE with PGA Message Set eCert No No Yes Failure to Present (FTP) Shipments Imported meat, poultry, and egg product that has entered commerce without FSIS import reinspection violates the FMIA, the PPIA, or the EPIA, as well as the implementing regulations for each Act (9 CFR 327.6; 381.199; 590.925). The importer of record is responsible for any product identified as FTP. FSIS will likely request that importers of record recall FTP product. Imported meat, poultry, and egg products are considered \u201cin-commerce\u201d when they are off-loaded at a location other than the official import inspection establishment or other FSIS approved location designated on the import inspection application. The FTP product is no longer eligible for reinspection. Product still in the original shipping container may

either be destroyed or returned to the country of origin. When a product has been identified as a FTP, FSIS will request, through CBP, a redelivery of the shipment and appropriate CBP penalties. As part of the Single Window initiative, FSIS is working with CBP to automate the redelivery process by December 2016, which will streamline enforcement of CBP redelivery requirements and meet the goals of Executive Order 13659. Customs has full authority to assess penalties and liquidated damages claims and to seize merchandise for violations of Customs or other laws enforced by the Customs Service. For more information about CBP redelivery requirements and penalties, please", "contact CBP\u2019s Office of Regulations and Rulings (<http://www.cbp.gov/contact/international-tradecontacts>). If any imported product identified as FTP has been removed from the original cartons or further processed, FSIS will initiate a regulatory control action on the product, including any further processed product that contains the FTP product, to ensure appropriate disposition (i.e., destruction). Prior Notification Q&As 1. What action will FSIS take if a shipment is presented for reinspection and FSIS did not receive the paper import inspection application in advance of the shipment\u2019s arrival at the official import inspection establishment? Answer: FSIS inspection program personnel will first check the PHIS Import Component to determine whether the IOR made entry with CBP using the PGA message set. If the IOR submitted the entry using the PGA message set, FSIS will proceed with the reinspection. If the IOR did not submit the entry using the PGA message set, FSIS inspection program personnel will identify the shipment in PHIS as a \u201cPrior Notification Violation.\u201d In addition, FSIS personnel will notify the IOR through the official import inspection establishment management of the violation, and that if violations continue, future shipments that do not meet the prior notification requirement will likely be refused entry. FSIS inspection program personnel will document the discussion with establishment management in a Memorandum of Interview (MOI) and then proceed with reinspection unless otherwise directed by FSIS management. If the shipment is not rejected, and FSIS proceeds with reinspection, the importer may experience unnecessary delays in the import inspection process if it does not meet this requirement. For prior notification violations, FSIS will consider using outreach (e.g., education and communication) with the IOR to ensure that prior notice requirements are understood. 2. Will there be allowances for legitimate, mitigating circumstances, e.g., when ACE is not operational? Answer: Under the final rule, the applicant is required to submit an Import Inspection Application in advance of the shipment\u2019s arrival, but no later than when the entry is filed with CBP (9 CFR 327.5, 381.198, 590.920). FSIS is committed to working through any ACE-to-PHIS Import Component data transfer problems to avoid any delays in completing reinspection. 3. How will prior notification apply to those who apply for import inspection electronically via the PGA Message Set? Answer: Applying for FSIS import inspection electronically via the PGA Message Set will fulfill the prior notification requirement. 4. How will prior notification apply to those who apply for import inspection with a paper-based application? Answer: For those importers or brokers using the paper-based import inspection application (FSIS Form 9540-1), FSIS must receive the paper application as far as possible in advance of the anticipated arrival of the consignment at the official import inspection establishment (or other FSIS approved location", "designated on the import inspection application), but no later than when the entry is filed with CBP (9 CFR 327.5(b), 381.198(b), and 590.920(b)). 5. How can I learn more about participating in the PGA Message Set? What kind of software or other upgrades do I need? Answer: More information can be

found in CBP\u2019s Federal Register Notice on the PGA Message Set. Regarding technical requirements, please consult CBP\u2019s website on ACE Automated Broker Interface (ABI) and CBP and Trade Automated Interface Requirements (CATAIR). FSIS will expand its PGA Message Set pilot to include all ports, as well as all interested importers and brokers by November 2015). Failure to Present (FTP) Q&As 6. How does FSIS define \u201cin-commerce\u201d for purposes of imported product that has bypassed reinspection and entered commerce? Answer: Imported meat, poultry, and egg products are considered \u201cin-commerce\u201d when they are offloaded at a location other than the official import inspection establishment or other FSIS approved location designated on the import inspection application. If the FTP product shipment is in-commerce, the imported product, or any product produced from the ineligible product, is subject to regulatory control action (i.e., FSIS would retain or detain the product if it is not returned to the importer of record), and FSIS may request that the importer of record recall the product. 7. Is transporting and storing imported product at a U.S. warehouse prior to reinspection considered a FTP? Answer: Yes. FSIS does not permit storing of imported meat, poultry, or egg products in a warehouse or other facility prior to reinspection unless the warehouse or facility has the same physical address as the official import inspection establishment (or other FSIS-approved location designated on the import inspection application), and it is physically connected to the establishment. Official import inspection establishment managers can notify FSIS import inspection personnel of the shipment\u2019s arrival to such a warehouse or facility, so that the status of the shipment can be changed to \u201cOn Premises\u201d in the PHIS Import Component so as not to be identified as FTP. 8. Will FSIS alert importers\agents to potential FTP product problems as soon as they are discovered? Answer: Yes. FSIS inspection program personnel are instructed in FSIS Directive 9900.1 to notify the applicant electronically (e-mail) through the PHIS Import Component when a shipment has not arrived at the official import inspection establishment or other FSIS-approved location designated on the import inspection application by the Estimated Date of Arrival (EDA) recorded on the import inspection application. When prompted, PHIS will automatically send the e-mail to the applicant e-mail address entered on the Import Inspection Application, which is completed by the IOR or his agent. FSIS will communicate and work with import inspection establishment management to track and control potential FTPs.", "9. Can FTP products be re-exported or removed from the U.S? Answer: If the product is still in its original containers it may be removed from the United States and returned to the country of origin as part of the disposition process with FSIS. However, FSIS cannot issue an FSIS export certificate for imported product subject to a FTP violation. In particular, the guidance covers: \u2022 The difference between initial validation and ongoing verification; \u2022 How to identify scientific support relevant to their process; \u2022 What are critical operational parameters and how to identify them in the scientific or technical support; \u2022 How to demonstrate that the critical operational parameters are being met during initial validation \(i.e., through the collection of in-plant validation data\); and \u2022 How an existing establishment can incorporate this guidance into their HACCP system. FSIS Compliance Guideline HACCP Systems Validation April 2015 i", "This Compliance Guideline follows the procedures for guidance documents in the Office of Management and Budget\u2019s \(OMB\) \u201cFinal Bulletin for Agency Good Guidance Practices\u201d \(GGP\). More information can be found on the Food Safety and Inspection Service \(FSIS\) Web page. This guidance has been revised in response to public comment. A summary of the comments received and responses to those comments can be found at <http://www.fsis.usda.gov/wps/wcm/connect/3ba826ec-6e79-4f17-85fc29200f4e8d05/2009-0019-2015.pdf?MOD=AJPERES>. It is important to note that this Guideline represents FSIS\u2019s current thinking on this topic and should be considered usable as of this issuance. Purpose The purpose of this guidance document is to aid small and very small establishments in meeting the initial validation requirements in 9 CFR 417.4. This document provides guidance to assist establishments in meeting FSIS regulations. Guidance represents best practice recommendations by FSIS, based on the best scientific and practical considerations, and does not represent requirements that must be met. Establishments may choose to adopt different procedures than those outlined in the guideline, but they would need to support why those procedures are effective. Is this version of the guideline final? Yes, this version of the guideline, dated April, 2015 is final. FSIS will update this guideline as necessary should new information become available, although comments will no longer be accepted through regulations.gov on this guideline. What if I still have questions after I read this guideline? If the desired information cannot be found within the Compliance Guideline, FSIS recommends that users search the publicly posted Questions & Answers \(Q&As\) in the AskFSIS database or submit questions through AskFSIS. Documenting these questions helps FSIS improve and refine present and future versions of the Compliance Guideline and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter HACCP Systems Validation Guideline Question Field: Enter question with as much detail as possible. Product Field: Select General Inspection Policy from the drop-down menu. Category Field: Select Sampling from the drop-down menu. Policy Arena: Select Domestic \(U.S.\) Only from the drop-down menu. ii", "When all fields are complete, press Continue. .....	64 iii","Who is this guidance designed for? This guideline is focused on small and very small establishments in support of the Small Business Administration\u2019s initiative to provide small and very small establishments with compliance assistance under the Small Business Regulatory Flexibility Act (SBRFA). However, all FSIS regulated meat and poultry establishments may be able to apply the recommendations in this guideline. It is important that small and very small establishments have access to a full range of scientific and technical support, and the assistance needed to establish safe and effective HACCP systems. Although large establishments can benefit from the guidance that FSIS provides, focusing the guidance on the needs of small and very small establishments provides them with information that may be otherwise unavailable to them.
	Why did FSIS develop this guidance document? FSIS has determined from its HACCP verification activities that many establishments have not properly validated their systems. In particular, establishments have not conducted adequate activities during the initial validation period to translate all the required critical operating parameters from the scientific or technical support into their processes and gather in-plant validation data demonstrating the HACCP plan is functioning as intended. In addition, Agency enforcement actions have identified instances in which inadequate validation has led to the production of adulterated product and in some cases even illnesses. Specific examples of when inadequate validation has led to the production

of adulterated product and in some cases illnesses are provided in Appendix 1. Based on the findings from FSIS data analyses and outbreak investigations summarized in Appendix 1, FSIS recommends that establishments use this guidance document to ensure that their HACCP systems are properly validated. While most establishments have assembled the scientific or technical support for the judgments made in designing their HACCP systems, which is the first element of initial validation, many establishments have not gathered the necessary in-plant validation data demonstrating that the HACCP system is functioning as intended. FSIS has also found establishments have not: HACCP System Design Issues \u2022 Identified scientific support that properly relates to the establishments\u2019 current processes; or \u2022 Identified the critical operating parameters in the scientific support necessary for the intervention to function as intended. Agency enforcement actions have identified instances in which inadequate validation has led to the production of adulterated product and in some cases even illnesses 1","HACCP System Execution Issues \u2022 Translated those critical operating parameters into their HACCP systems; or \u2022 Documented that they have validated their HACCP systems under actual in-plant conditions. By ensuring that the HACCP system is designed and executed properly, an establishment can reduce the likelihood for product contamination and illnesses in the future. Initial validation of any HACCP system must include scientific or technical support related to the establishment\u2019s process supporting the design of the HACCP system along with some practical in-plant validation data reflecting an establishment\u2019s actual early experience in executing the HACCP system. Validation must demonstrate not only that the HACCP system is theoretically sound (design), but also that the establishment can implement it and make it work (execution). What concepts and skills will small and very small establishments learn from this guidance? Small and very small establishments that utilize this guidance will learn: \u2022 The difference between initial validation and ongoing verification; \u2022 How to identify scientific or technical support relevant to their processes; \u2022 What are critical operational parameters and how to identify them in the scientific and technical support; and \u2022 How to demonstrate that the critical operational parameters are being met during initial validation (i.e., through in-plant validation data). Establishments that understand these topics should have the tools needed to successfully validate their HACCP systems. What is the history of validation in the context of the HACCP regulations? On July 25, 1996, FSIS published a final rule on Pathogen Reduction; Hazard Analysis and Critical Control Point (HACCP) Systems (PR\HACCP) (61 FR 38806). The PR\HACCP rule requires that meat and poultry establishments under Federal inspection take responsibility for, among other things, reducing the contamination of meat and poultry products with disease-causing (pathogenic) bacteria by implementing a system, known as HACCP, of preventative controls designed to improve the safety of their FSIS stated in the HACCP Final Rule that validation data for any HACCP system must include practical data or information reflecting an establishment\u2019s actual experience in implementing the HACCP system 2","products. An establishment must have an effective HACCP system to comply with regulatory requirements and prevent adulteration of product. The HACCP requirements that establishments must meet are set out in 9 CFR Part 417. These requirements are based on the seven HACCP principles recommended by the National Advisory Committee on Microbiological Criteria for Food (NACMCF) in 1992. One of the principles identified by the NACMCF was \u201cVerification\u201d describing that HACCP systems should be systematically verified. In

the NACMCF explanation of the verification principle, which FSIS follows, an establishment is responsible for the following three processes encompassing the verification principle: \u2022 Validation, \u2022 Verification, and \u2022 Reassessment NOTE: This guidance document speaks only to the initial validation component of the verification HACCP principle. The recommendations in the verification principle form the basis for the requirements in 9 CFR 417.4. This section requires that every establishment validate the HACCP plan\u2019s adequacy in controlling the food safety hazards identified in the hazard analysis, verify that the plan is being effectively implemented on an ongoing basis, and reassess the plan at least annually, or when an unforeseen hazard or change occurs, or whenever any changes occur that could affect the hazard analysis or alter the HACCP plan. Although the HACCP regulations were implemented over 15 years ago, FSIS has found through Food Safety Assessments (FSAs) that establishments have not complied with the initial validation requirement. In particular, establishments have not collected the necessary in-plant validation data demonstrating that the HACCP system is functioning as intended. Therefore, FSIS determined that additional validation guidance for HACCP systems is needed. Key definition HACCP is a scientific system for process control that has long been used in food production to prevent problems by applying controls at points in a food production process where hazards could be controlled, reduced, or eliminated. The HACCP system is defined as the HACCP plan in operation, including the HACCP plan itself. The HACCP plan in operation includes the hazard analysis, any supporting documentation including prerequisite programs supporting decisions in the hazard analysis, and all HACCP records. Key Requirement 9 CFR 417.4(a)(1) requires \u201cupon completion of the hazard analysis and development of the HACCP plan, the establishment shall conduct activities designed to determine that the HACCP plan is functioning as intended. During this HACCP plan validation period, the establishment shall repeatedly test the adequacy of the CCP\u2019s, critical limits, monitoring and recordkeeping procedures, and corrective actions set forth in the HACCP plan. Validation also encompasses reviews of the records themselves, routinely generated by the HACCP system, in the context of other validation activities.\u201d 3", "What is HACCP System Validation? Validation is the process of demonstrating that the HACCP system as designed can adequately control potential hazards to produce a safe, unadulterated product. Validation encompasses activities designed to determine whether the entire HACCP system is functioning as intended. Validation of a HACCP system involves two separate elements 1) design and 2) execution. Under 9 CFR 417.4(a)(1) establishments are required to assemble two types of supporting documentation to demonstrate these elements are met: 1. The scientific or technical support for the HACCP system design (design) - that is the theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards; and 2. The in-plant validation data (execution) - that is the in-plant observations, measurements, microbiological test results, or other information demonstrating the control measures in the HACCP system can perform as expected within a particular establishment to achieve the intended food safety objective. Under 9 CFR 417.5(a)(1) and 9 CFR 417.5(a)(2), these supporting documents must be kept for the life of the plan. The two elements will be discussed in detail throughout this document. In summary, to validate the HACCP system, establishments should:

4 Element 1: Scientific or Technical Support (Design)

\u2022Gather scientific or technical support (e.g., published processing guidelines, journal articles, challenge studies, etc.) for its HACCP system that:

- \u2022Closely matches the actual process; and
- \u2022Shows that the establishment's process prevents, reduces, or eliminates the hazard identified in the hazard analysis; and
- \u2022Identifies the critical operational parameters from the scientific support relevant to the establishment's process

Element 2: Inplant Validation Data (Execution)

- \u2022Implements critical operational parameters in the actual production process consistent with the parameters in the scientific or technical support;
- \u2022Identifies at least one product from each HACCP category to gather in-plant validation data;
- \u2022Collects in-plant data demonstrating the effectiveness of the implementation of the critical operational parameters for at least one product from each HACCP category; and
- \u2022Analyzes the data to determine whether the critical operational parameters are being implemented effectively.

"What is the definition of a HACCP System, and do prerequisite programs have to be validated? Validation of the HACCP system involves validation of the critical control points in the HACCP plan, as well as of any interventions or processes used to support decisions in the hazard analysis. The regulations provide that \"[v]alidation \u2026 encompasses reviews of the records themselves, routinely generated by the HACCP system, in the context of other validation activities\" (9 CFR 417.4(a)(1)). Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). Said differently, when an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis (Element 1 of validation) and must collect in-plant validation data to support that the programs are implemented as designed (Element 2). For this reason, the HACCP system rather than the HACCP plan only is discussed throughout the rest of this document.

**KEY QUESTION** Question: Are establishments required to collect in-plant microbiological data to comply with the initial validation requirements? Answer: FSIS encourages establishments to gather in-plant microbiological data as part of in-plant validation data but does not require that they do so, provided that the establishment has adequate scientific or technical support (the first element of validation), is following the parameters in the scientific or technical support, and can demonstrate that it can meet the critical parameters during operation through in-plant validation data (the second element of validation). A discussion of scientific and technical support can be found beginning on page 6 and a discussion of in-plant data can be found beginning on page 20.

5", "What is the first element of HACCP Systems Validation? The first element of HACCP systems validation is the scientific or technical support that demonstrates that the HACCP system is theoretically sound. To meet the first element of validation, establishments should:

- \u2022 Gather scientific or technical support (e.g., published processing guidelines, journal articles, challenge studies, etc.) for its HACCP system that:
  - o Closely matches the actual process; and
  - o Shows that the establishment's process prevents, reduces, or eliminates the hazard identified in the

hazard analysis; and \u2022 Identify the critical operational parameters from the scientific or technical support relevant to the establishment\u2019s process. The scientific or technical support should reflect current thinking and not be outdated. In order to identify scientific or technical support that closely matches the actual process, establishments should understand the major types of scientific and technical support documents. What are the major types of scientific and technical support documents used to satisfy the design element of HACCP Systems Validation? There are several types of documents that can be used as scientific and technical support. These include:

1. Published processing guidelines that achieve a stated reduction of a pathogen are examples of scientific support. The time-temperature guidelines in Appendix A of the final rule \u201cPerformance Standards for the Production of Certain Meat and Poultry Products\u201d (64 FR 746-748) is an example of a guideline that addresses process lethality. The guidelines in Appendix B, Compliance Guidelines for Cooling HeatTreated Meat and Poultry Products (Stabilization), address product stabilization to meet the requirements of 9 CFR 318.17(a)(2), 9 CFR 318.23(c)(1), and 9 CFR 381.150(a)(2). Published processing guidelines are not limited to those published by FSIS. Published guidelines from other agencies, trade organizations, or universities can also be used as scientific support. Extension publications may also be cited as scientific support; however, extension publications often reference the original journal articles that were used to develop the support. In those cases, establishments should have the original journal articles on-file referenced in the extension publication because the extension publications often do not include all of the critical operational parameters that establishments would need to implement. Establishments need information on all the critical operational parameters in order to determine whether the process in the publication matches their actual process.
2. Peer-reviewed scientific or technical data or information that describe a process, and the results of the process can provide adequate scientific or technical support. This type of support could include journal articles, graduate student theses, or information found in a textbook. All of these types of scientific data go through a process of evaluation involving qualified individuals within the relevant field. In addition to describing the microbiological results of the process, the data may also describe the role intrinsic and extrinsic product factors play on the growth of microorganisms. For example, a textbook may contain data on the growth limits of certain pathogens based on a food product\u2019s water activity and pH. For journal articles, the study should relate closely to the establishment\u2019s process with regards to species, product characteristics, and equipment (to the extent that the use of different equipment would result in an inability to achieve the critical parameters of the study). The establishment should use the critical operational parameters cited in the journal article that achieve the required or expected lethality or stabilization if the establishment does not intend to perform additional research to validate its process. In addition, for biological hazards, the scientific article should contain microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis. A lack of microbial data in the scientific support could raise questions concerning whether the process design has been adequately validated. NOTE: Most scholarly journals use a process of peer review before publishing an article. As part of the review, scholars with expertise in the topic addressed by the draft article critically assess the article. Peer-reviewed journals only publish articles that have passed through a review process. The review process helps ensure that published articles

contain solid research work. If an establishment uses scientific or technical data that is not peer-reviewed, the establishment may be subject to additional scrutiny by Agency personnel performing verification activities. 3. Expert advice from processing authorities may also be used as scientific or technical support. Such expert advice may include reference to established scientific principles as well as reference to peer-reviewed scientific data. Expert advice from processing authorities should not rely on expert opinion alone. The scientific principles and data should relate to the establishment's product and process as well as the hazard identified in the hazard analysis. One example of how expert advice may be used is a processing authority's justification for why a different level of a critical operational parameter from the one studied in the scientific support should be used. Key definitions Intrinsic factors are those inherent parameters of a food that affect the growth of microorganisms. Examples of intrinsic factors include, among other things, pH, moisture content, water activity, and nutrient content. Extrinsic factors are those parameters that are external to the food that affect the growth of microorganisms. Examples of extrinsic factors include, among other things, temperature of storage, time of storage, and relative humidity.

"not impact the effectiveness of an intervention. As part of the justification, in addition to their own expert opinion, the processing authority should cite one or more peer-reviewed scientific data sets or documents that provide a science-based rationale for why the different level of the critical operational parameter should be at least equally as effective from the one in the scientific support. Another example of how expert advice from a processing authority may be used is as support for a scheduled process to produce a commercially sterile product. Prior to the processing of canned product for distribution in commerce, an establishment must have a process schedule for each canned meat or poultry product to be packed by the establishment. The process schedule used by an establishment is developed or determined by a processing authority. Any changes that may adversely affect the adequacy of the process must also be evaluated by a processing authority and that process schedule amended accordingly. When developing the process schedule, the processing authority should take into account established scientific principles as well as peer-reviewed scientific data in order to establish a thermal process that will specify the amount of time at a specific temperature necessary to ensure the destruction of *Clostridium botulinum* and spoilage organisms that may be present.

4. A challenge or inoculated pack study that is designed to determine the lethality or stabilization of a process also is an example of scientific support. These studies are performed in a laboratory or pilot plant by a processing authority or expert and sometimes can be accessed through the internet. The documentation on file should specify the level of pathogen reduction, elimination, or growth control (e.g., for stabilization); describe the process, including all critical parameters affecting the reduction or elimination; and give the source of the documentation. Such studies are often not published in peer-reviewed journal articles but should contain the same level of detail as is provided for peer-reviewed studies. Challenge studies should be based on a sound statistical design (i.e., a statistical design that ensures confidence in the data) and should also employ positive and negative controls. The statistical design should include the number of samples collected at each time interval and the number of study replicates needed to ensure the validity of the study. There are quantitative methods for assessing the statistical quality of a study (e.g., power analysis). As recommended by the National Advisory Committee on Microbiological Criteria of Foods (NACMCF), the number of samples to be analyzed initially and at each time interval

during processing or storage should be at least two; however, NACMCF recommends analysis of three or more samples. According to NACMCF, replicates should also be conducted. Replicates should be independent trials using different lots of product and inoculum to account for variations in product, inoculum, and other factors. When the number of samples analyzed at each time interval is only two, it is better for the study to be repeated (replicated) more than two times. In studies with three or more samples tested at each time interval, two replicates are usually adequate. NOTE: For more information on conducting challenge studies, please review the article, "Parameters for Determining Inoculated Pack/Challenge Study Protocols," published by the National Advisory Committee on Microbiological Criteria for Foods in the Journal of Food Protection in 2010. For more information on the use of positive and negative controls in challenge studies as well as general guidance on how to select a microbiological testing laboratory please review FSIS' 2019 Establishment Guidance for the Selection of a Commercial or Private Microbiological Testing Laboratory.

5. Pathogen modeling programs are computer-based software that, based on such factors as growth, lethality, and survival in culture broth and food products, estimate the growth or decline of foodborne microbes in food samples in production. Examples of uses of pathogen modeling programs include those to support the development of custom cooling schedules; to support product safety following heating, cooling, and storage deviations; and to support the use level of antimicrobial agents. Establishments may use the results of modeling programs as scientific support provided that the establishment inputs accurate values into the modeling program, and that the modeling program has been validated for the product in question. Validation data for the model is often provided along with the modeling program or can be obtained by contacting the model developer. The modeling program chosen should also be specific for the pathogen identified in the hazard analysis. If the modeling program has not been validated for the product in question, the establishment should provide additional scientific support for its use. Such additional support could include in-plant data showing routine levels of pathogens in the product, or documentation addressing the production of the raw materials and the product's intended use. Establishments should have the modeling results on-file for review and should have documentation supporting the values entered into the model (e.g., time-temperature profile data, pH, salt concentration).

6. Data gathered by the establishment in-plant can also be used to validate a process as part of a research study or other study. This data gathering can be done if the establishment could not implement the process as documented in the literature within its processing environment. Examples of this approach could be if an establishment is introducing a new technology not established in the literature or applying a standard technology in an unusual way (e.g., modifying critical operational parameters from the literature). In these cases the establishment should gather scientific support and in-plant validation data for its HACCP system under commercial operating conditions. For example, microbiological data may show that a steam vacuum process is achieving a certain level of reduction for the specified microorganism. If the establishment is modifying the critical operational parameters of the steam vacuum process then the documentation gathered in-plant used to show that the HACCP system is valid as designed should contain information from all the tests performed, such as temperature of steam, time of exposure, and microbiological results of swab tests, and information that makes clear whether the testing was performed on a routine or specified schedule. When collecting data in-plant, the

establishment should develop a sampling plan in advance of data collection to ensure that the data collected are adequate to make statistical determinations about effectiveness. 9", "In-plant data could also be collected as technical support for an establishment\u2019s HACCP system design. For example, an establishment may identify foreign material as a hazard in ground product because of the wooden pallets it uses, and how the product is loaded to be dumped into a hopper. The establishment could determine that the foreign material hazard is not reasonably likely to occur because of a prerequisite program that includes steps the establishment takes to ensure that pieces of the pallet do not break off and fall into the grinder to contaminate the product. The establishment could collect in-plant data to demonstrate the effectiveness of these technical procedures for preventing the hazard from occurring in its process. Large corporations with multiple establishments often conduct studies in one establishment to gain scientific information to validate an intervention\u2019s design and then extend the use of the intervention to other establishments within the corporate umbrella. For the establishment at which the data were gathered, FSIS would consider the data to be data gathered in-house, and thus the data would meet both parts of validation (design and execution). However, for the establishments to which use of the intervention was extended, the data would meet only the first element of validation. To meet the second element of validation, the corporation would still need to demonstrate that the intervention will function as intended in each of those establishments by gathering data on the critical operating parameters\u2019 execution in those additional establishments. So, for biological hazards, microbial data collected at one establishment could be used to support effectiveness of the intervention or process (i.e., the first element of validation) at other establishments within the corporation that use the same procedures.

7. Regulatory performance standards, as defined in the Code of Federal Regulations, that outline specific prescribed procedures such as time\temperature combinations, product storage conditions, or product reconditioning procedures. The poultry chilling requirements defined in 9 CFR 381.66 or the trichinae requirements in 9 CFR 318.10 would be examples of instances where the regulations clearly define the performance standard for a processing step and can be used to support the HACCP system design.

8. Best practice guidelines are another example of scientific or technical support. These guidelines generally contain a list of procedures or a set of principles that have been identified by experts as having a scientific or technical basis for preventing a hazard from occurring when implemented. For example, the Beef Industry Food Safety Council (BIFSCO) has developed a document that contains Best Practices for Beef Slaughter. This document may be used as scientific support that an establishment\u2019s sanitary dressing program prevents contamination with NOTE: FSIS does not advocate the introduction of pathogens in the plant environment.

10", "microbiological hazards such as STEC and ensures that the interventions the establishment has in place achieve their intended effect. What are some examples of incomplete scientific or technical support? The following are examples of incomplete scientific or technical support for validation:

- \u2022 Documentation that specifies the log reduction achieved by the process but that does not include information about critical parameters, such as pH, critical to achieving that reduction. That information should be included in order for the process to be considered validated.
- \u2022 Having a validated process on file but not following the process described.
- \u2022 Validating a process for a specific log reduction of a pathogen in a product other than meat and poultry. This validation data alone would not be sufficient

scientific support. For example, a process that achieves a 5-log reduction of E. coli O157:H7 in apple cider would not be sufficient scientific support for the reduction of E. coli O157:H7 in a beef product process. \u2022 Implementing an intervention based on scientific or technical support that did not contain data supporting the process\u2019s effectiveness. For example, implementing a lactic acid intervention in a prerequisite program to support E. coli O157:H7 as a hazard not reasonably likely to occur but maintaining scientific support with microbiological data for Salmonella. NOTE: Ensuring that the scientific support contains microbiological data for the hazard listed in the hazard analysis is particularly important for slaughter processes where interventions have different efficacy depending on the species of product and the pathogen. In other cases, such as for lethality processes, Salmonella may be used as an indicator of lethality for other pathogens. \u2022 Documentation in the form of a No Objection Letter or FSIS Directive 7120.1 without additional scientific or technical support that provides information on the levels of all of the critical operational parameters used, and without support that demonstrates the effectiveness of the new ingredient or technology against the specific hazards identified in the hazard analysis. Examples of such necessary scientific and technical support are included on pages 6 through 11 of this document. This additional support is needed because the No Objection Letter and FSIS Directive 7120.1 Safe and Suitable Ingredients Used in the Production of Meat and Poultry Products do not contain efficacy data or data on all of the critical operational parameters. \u2022 Expert opinion from a processing authority stating the growth limit of a pathogen without any reference to established scientific principles or peer-reviewed data. 11", "How can an establishment identify whether the scientific or technical support closely matches the process, product, and hazard analysis? In all cases, the scientific or technical support should identify: \u2022 The product studied (including formulation and intrinsic factors) \u2022 The hazard (biological, physical, or chemical), \u2022 The expected level of hazard reduction or prevention to be achieved, \u2022 All critical operational parameters or conditions necessary, \u2022 The processing steps that will achieve the specified reduction or prevention, and \u2022 How these processing steps can be monitored. The establishment should evaluate this information to determine whether it\u2019s scientific or technical support is sufficiently related to the process, product, and hazard identified in the hazard analysis. The scientific or technical support should be complete and available for FSIS review, so that FSIS personnel can also determine whether the support is sufficiently related to the actual process. Failure to take these steps would raise questions about whether the HACCP system has been adequately designed and validated. How can an establishment identify scientific support that adequately addresses the expected level of hazard reduction or prevention to be achieved for biological hazards? The type of scientific support (e.g., published processing guideline, peer-reviewed data or information, pathogen modeling program results) and the type of data or information contained in the support will differ depending on the product, biological hazards identified in the hazard analysis, and the intervention strategy the establishment designs to reduce, eliminate, or prevent the hazards. Some of these considerations for identifying scientific support for intervention strategies used to address hazards in RTE and raw products are outlined below. Scientific Support for RTE Products Establishments producing meat or poultry products that are RTE must support that potential hazards have been addressed in the product according to 9 CFR 417.2(a)(1). The Listeria Rule (9 CFR 430.1) defines RTE products as meat or poultry products that are edible without additional

preparation to achieve food safety. To support that products are RTE, among other steps, establishments need to achieve lethality of pathogens in the product. To support decisions in the hazard analysis related to lethality of pathogens RTE products, establishments must provide scientific support that specifies the expected level of pathogen reduction achieved by the intervention strategy for the product being produced. For example, establishments producing RTE semi-dry fermented products must provide scientific support that the fermentation and drying steps achieve a specific level of pathogen reduction. In the *Salmonella Compliance 12*,"*Guidelines for Small and Very Small Meat and Poultry Establishments that Produce Ready-to-Eat (RTE) Products*, FSIS recommends that these processes achieve at least a 5.0-log<sub>10</sub> reduction on of *Salmonella* spp. Without data demonstrating a specific log reduction is achieved, it would be difficult for an establishment to support that a product is RTE. The scientific support for RTE products should be sufficiently related to the process, product, and hazard identified in the hazard analysis. For thermal lethality treatments (i.e., cooking), establishments can use scientific support that demonstrates reduction in one pathogen to support that another pathogen would also be reduced. For example, although establishments may identify several biological hazards (i.e., *Salmonella*, *Listeria monocytogenes* (Lm), and *E. coli* O157:H7) that are addressed by a lethality treatment, *Salmonella* is generally considered the reference organism for lethality for most RTE meat and poultry products because: (1) It is prevalent in raw poultry, beef, and pork; (2) it causes a high incidence of foodborne illness; and (3) foodborne illness associated with *Salmonella* is severe (66 FR 12593). In addition, FSIS recommends that establishments use *Salmonella* as an indicator of lethality because it tends to be more heat resistant than other pathogens. Therefore, if an establishment's scientific support demonstrates that its lethality treatment achieves sufficient reduction in *Salmonella*, it does not need to provide additional support that adequate reduction in other pathogens such as Lm or *E. coli* O157:H7 is achieved. For these reasons, establishments should not use pathogens other than *Salmonella* as indicators of lethality unless they can provide support that the pathogen studied displays similar resistance to the process that destroys the bacteria (e.g., heat, acid, or drying). For example, establishments should not use scientific support demonstrating reductions in Lm from a lethality treatment to support that similar reductions in *Salmonella* would be achieved without support that Lm is at least equally as resistant as *Salmonella* under the conditions being studied. Non-pathogenic indicator organisms may be used and will be discussed in a later section. KEY QUESTION Question: Can an establishment use Appendix A, which was designed to address *Salmonella*, to support other pathogens such as *E. coli* O157:H7 or *Listeria monocytogenes* are controlled? Answer: Yes, an establishment can cite Appendix A as support that *E. coli* O157:H7 and *Listeria monocytogenes* are controlled as a result of a thermal process. Although Appendix A was developed based on experiments measuring the efficacy of thermal processes on *Salmonella*, *Salmonella* can be used as an indicator of lethality for other pathogens such as *E. coli* O157:H7 and *Listeria monocytogenes*. 13","*Scientific Support for Raw Products Under 9 CFR 417.2(a)(1)*, establishments producing raw meat or poultry products must support that potential hazards have been addressed in the product. For the production of raw products, the scientific support should contain microbiological data specifying the expected level of pathogen control or prevention achieved by the intervention strategy so that the establishment can determine whether the intervention is adequate for its product and process. Using documentation that does not contain

microbiological data on the specific level of reduction achieved could represent a vulnerability in an establishment's HACCP system design. For example, an establishment that identifies Salmonella as a hazard reasonably likely to occur in its poultry slaughter process because it has historically occurred would have a vulnerability in its process if it relies on scientific support that contains the number of samples that test positive for Salmonella before and after the application of an intervention. Using this type of data would represent a vulnerability because it would not provide information on the specific log reduction achieved. Without this information, the establishment would be unable to determine whether the intervention would reduce Salmonella in its process to acceptable levels. The scientific support for raw meat and poultry products should also be sufficiently related to the process, product, and hazard identified in the hazard analysis. It is particularly important that the scientific support for intervention strategies used in the production of raw products include microbiological data that specifies the expected level of pathogen reduction for the same hazard identified in the hazard analysis. For example, in slaughter establishments, interventions such as lactic acid and peroxyacetic acid (PAA) have been found to perform differently for different pathogens (e.g., Salmonella and E. coli O157:H7) and different species (e.g., poultry vs. beef). Therefore, it would be important for a beef slaughter establishment that references a lactic acid intervention applied to beef carcasses as a control for E. coli O157:H7 in its hazard analysis during slaughter and dressing to provide support that a specific log reduction in E. coli O157:H7 is achieved when the lactic acid is applied to beef carcasses. One exception when the scientific support may not need to address the specific pathogen listed in the hazard analysis for raw products is for intervention strategies designed to control or prevent non-O157 shiga-toxin producing Escherichia coli (STEC). At this time, FSIS is not aware of any controls specific to non-O157 STEC. Interventions validated to control E. coli O157:H7 should be effective in controlling non-O157 STEC when properly implemented as described in the establishment's scientific support. Can establishments use scientific support containing microbiological data from indicator or surrogate organisms? In general, establishments should not rely on scientific support containing data only from indicator or surrogate organisms unless there is sufficient data to establish a relationship between the presence or level of a pathogen or toxin and the indicator organism. When selecting the appropriate surrogate organism, the establishment 14", "should consider the process that destroys the bacteria (e.g, heat, acid, drying). For example, a surrogate organism that is at least as heat resistant as the pathogen of concern should be used if the process primarily relies on thermal destruction (i.e., heat). If the primary pathogen reduction mechanism is fermentation, then a surrogate should be at least as acid resistant as the pathogen of concern. The surrogate chosen in each of these situations may not be the same. Data demonstrating a relationship between the presence or level of a pathogen or toxin and the indicator organism can be collected from studies using indicator organisms that parallel the data in a challenge study performed with the inoculated pathogen. This data could be collected by performing the study with the indicator and pathogen as part of a single study or separately in two studies performed under similar conditions. If similar and consistent reduction or control can be established, then control of the indicator organisms can be reliably used to indicate expected pathogen control in actual application. An example of when similar and consistent reduction in an indicator or surrogate organism and a pathogen have been found is research that was done by the University of Wisconsin with ground-and-

formed jerky that found that two *Pediococcus* strains (Saga 200 and Biosource) have similar heat-resistance to *Salmonella* and can be used in validation studies (Borowski et al., 2009) for jerky lethality processes. In addition, FSIS has identified four surrogate organisms that have been shown to respond similarly to *E. coli* O157:H7 during cooking (see the following askFSIS Q&A1 for more information) for use in validation studies designed to demonstrate a reduction in *E. coli* O157:H7. At this time, however, FSIS is not aware of supporting documentation demonstrating a strong correlation to support the use of generic *E. coli* testing in lieu of testing for *E. coli* O157:H7 or non-O157 STEC. How can an establishment identify scientific or technical support that adequately addresses the expected level of hazard reduction or prevention to be achieved for physical and chemical hazards? For physical and chemical hazards, establishments will often use technical support to demonstrate that particular process control measures can adequately address specific hazards. As with biological hazards, the scientific or technical support should closely match the product, process, and hazard. For example, if the establishment uses detection equipment to identify foreign material such as metal in a particular product, it should have technical support on-file that demonstrates that the equipment can in fact detect the targeted materials (e.g., metal of a defined size and type) in the product. The same is true for chemical hazards. For example, an establishment that uses a lactic acid intervention during a beef slaughter process may identify a chemical hazard from [http://askfsis.custhelp.com/app/answers/detail/a\\_id/1392/kw/surrogate/session/L3RpbWUvMTMyNzUyMTY0Ni9zaWQvVFR6c3cyUGs%3D15](http://askfsis.custhelp.com/app/answers/detail/a_id/1392/kw/surrogate/session/L3RpbWUvMTMyNzUyMTY0Ni9zaWQvVFR6c3cyUGs%3D15), "excessive levels of lactic acid. The establishment may support that the hazard is not reasonably likely to occur based on instructions from the manufacturer on mixing the lactic acid with water to achieve a concentration that is safe and suitable in accordance with FSIS Directive 7120.1. In this case, the manufacturer's instructions or conditions of use are often provided as technical support that demonstrates the use of the chemical is controlled. How can an establishment identify scientific support for prerequisite programs? As previously discussed on page 5, when an establishment determines that a hazard is not reasonably likely to occur because the implementation of a prerequisite program prevents the hazard from occurring, that prerequisite program becomes part of the HACCP system. Therefore, prerequisite programs designed to support decisions in the hazard analysis (e.g. Sanitation Standard Operating Procedures [Sanitation SOPs], written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) must be validated to ensure that the overall system can operate effectively. Although prerequisite programs within HACCP systems are often designed as multiple hurdles of control, establishments should be able to provide scientific or technical support that each hurdle or combination of hurdles provides the necessary level of prevention for the identified hazards. For some prerequisite programs that are implemented at a discrete point or step in the process, such as those for antimicrobial interventions, the guidance provided on the previous pages for identifying scientific support for the expected level of reduction necessary to prevent the hazard can be applied. When using an antimicrobial intervention as a prerequisite program, establishments should identify scientific support that matches the product, process, and hazard and that contains microbiological data specifying the expected level of pathogen reduction necessary to prevent the hazard from occurring. For other prerequisite programs that are implemented across multiple points or steps in the process, such as those for allergen control or programs

that incorporate written sanitary dressing procedures, establishments may rely on scientific or technical support that contain best practices regarding the implementation of such programs. For example, the Beef Industry Food Safety Council (BIFSCO) has developed a document that contains Best Practices for Beef Slaughter. FSIS has identified, through both scientific literature review and best practice guidance created by industry, the points in the slaughter process where carcasses are most vulnerable to contamination and has included these steps in FSIS Directive 6410.1 Verifying Sanitary Dressing and Process Control Procedures by Off-line Inspection Program Personnel (IPP) in Slaughter Operations of Cattle of Any Age. These documents may be used as scientific support that an establishment's sanitary dressing program prevents contamination with microbiological hazards such as STEC and ensures that the interventions the establishment has in place achieve their intended effect. See Appendix 4 page 55 for an example of scientific support and in-plant data that could be collected to validate Sanitation SOPs, page 56 for an example of scientific support and in-plant data that could be collected to validate a temperature control prerequisite program, and page 57 for an example of scientific support and in-plant data that could be collected to validate a sanitary dressing program. What are the critical operational parameters of a process, and how does an establishment identify them in its scientific support? Critical operational parameters are the specific conditions that the intervention must operate under in order for it to be effective. For an establishment to validate an intervention, it should first identify the critical operational parameters within its process that it needs to implement and monitor. These critical operational parameters are identified in documents gathered as part of Element 1 of validation and often include but are not limited to: Time pH Temperature Contact Time Concentration Product Coverage Humidity Spatial Configuration Dwell Time Pressure Water Activity Equipment Settings or calibration To be effective, the process procedures should be consistent with the critical operational parameters in the scientific support. For example, if the scientific support listed a particular critical operational parameter such as the concentration of an antimicrobial, that same concentration should be used in the process. In some cases, establishments may be able to support using different levels of a critical operational parameter than that used in the support. For example, an establishment may be able to provide a justification for why using a higher lethality temperature than that used in the scientific support would result in the same level of pathogen reduction. When different levels of a critical operational parameter than those in the support document are used, establishments should consider developing a decision-making document that explains the scientific rationale for why the different level would not affect the efficacy of the intervention or process. See Appendix 2 for an example. This scientific rationale could be provided by a processing authority or other expert provided there is reference to established scientific principles or peer-reviewed scientific data and does not rely on expert opinion alone. Developing a decision-making document and explaining the rationale for use of a critical operational parameter different from the one in the scientific support is important because changing a critical operational parameter can impact the intended result in unexpected ways. For example, antimicrobials have been determined to be safe and suitable up to specific concentrations at specific pH levels as listed in FSIS Directive 7120.1 and 9 CFR 424.21(c)). Although the Directive and regulation provide maximum allowable concentrations for

antimicrobials, the establishment needs to determine the 17", "optimum concentration for its process based on the critical operational parameters in its scientific support (e.g., journal articles, challenge studies). The concentration chosen by an establishment is often the concentration at which maximum efficacy is observed. A synergistic or an additive effect may be observed when combinations of antimicrobials are used. Above the optimum concentration, although still within the allowable range, the chemical or antimicrobial efficacy decreases because the cells\membrane of the microorganism are saturated with the compound, and further inactivation of the bacteria is not observed. In other words, more of an antimicrobial is not always better. An establishment may be able support using a higher concentration of an antimicrobial in its process than that used in the scientific support but within the allowable range, provided that it evaluates whether changes to the concentration would affect the efficacy of the intervention or process, and that there is scientific support for its decisions. To identify the critical operational parameters when evaluating the scientific support, there are several questions one can ask. For example: \u2022 What parameters were measured in the research? \u2022 Where in the process or on the product were the measurements taken? o Is the establishment taking measurements in these locations? \u2022 What parameters, if any, were held constant across experimental conditions? \u2022 What parameters, if any, were varied or changed in the research? o When these parameters were changed, did the effectiveness of the intervention change as well? o If so, are these parameters that you have considered in your process? \u2022 Did the authors provide some guidelines as to the limitations of the research or any cautions against applying the findings outside of the scope of the study? o For example, were there some parameters that were controlled in the laboratory that differ in-plant that you should be aware of? o If so, have you considered if those apply to your process? If the scientific support does not document the measurement of a critical operational parameter, the establishment should evaluate whether this parameter really needs to be met or measured, or whether additional support is needed for the level of that parameter in the actual process. For example, humidity is a critical operational parameter in the cooking or heating of many ready-to-eat meat and poultry products. For the production of some of these products, however, humidity does not need to be met or measured. For example, as addressed in the Appendix A Guidance on Relative Humidity and Time\Temperature for Cooking\Heating and Applicability to Production of Other Ready-to-eat Meat and Poultry Products, humidity does not need to be met or measured when a product is cooked in a sealed, moisture impermeable bag. Establishments producing such cook-in-bag products may develop a decision-making document and cite the Appendix A Guidance on relative humidity as support for why humidity does not need to be met or measured in the process. What is important in this case is that the establishment considers the parameters that are relevant for their product and process 18", "and does not assume that just because the parameter was not measured in the scientific support it is not important. For prerequisite programs that are implemented across multiple points or steps in the process, such as those for allergen control or programs that incorporate written sanitary dressing procedures, establishments may rely on scientific or technical support that contains best practices regarding the implementation of such programs. When relying on these types of scientific or technical support, establishments may consider the recommended procedures that should be incorporated into the written prerequisite program as critical operational parameters. These procedures would be considered critical operational parameters

because these steps need to be implemented and monitored in order to ensure that the program is effectively preventing a hazard from occurring. See Appendix 3 for additional guidance as to how to identify critical operational parameters from the scientific support. Appendix 4 contains examples of critical operational parameters that have been identified for different types of processes and scientific support. Examples of the types of in-plant documentation expected are also provided. Key Point: An establishment that gathers scientific support for its processes (and properly identifies the critical operational parameters in the support) as described above would meet the threshold indicated in the HACCP Systems Final Rule (61 FR 38806) for the first element of initial validation in designing a valid HACCP system. The establishment's processes would be considered by FSIS to be based on or supported with documented scientific evidence. These processes would not need any additional scientific support as part of the initial validation process. However, as stated in the HACCP Systems Final Rule (61 FR 38826), an establishment introducing a new technology not established in the literature or applying a standard technology in an unusual way (e.g., modifying critical operational parameters from the literature) should gather scientific support and in-plant validation data for its new or modified HACCP system under commercial operating conditions. The effort to develop such information may require that the establishment conduct, or have conducted for it, scientific studies either in a laboratory setting, pilot plant, or in-plant. An establishment that lacks experience with a technology should also gather scientific support and in-plant validation data with the exception of when the effectiveness of the new technology has already been studied, but the establishment lacks experience implementing the technology. In this case, the effort to develop such information may focus more on the collection of in-plant validation data (discussed further in the next section). 19", "What is the second element of HACCP Systems Validation? The second element of HACCP systems validation is initial in-plant validation which may include in-plant observations, measurements, microbiological test results, or other information demonstrating that the control measures, as written into a HACCP system, can be executed within a particular establishment to achieve the process's intended result (61 FR 38806, 38826 (July 25, 1996)). FSIS stated in the HACCP Final Rule that validation data for any HACCP system must include practical data or information reflecting an establishment's actual experience in implementing the HACCP system. The validation must demonstrate not only that the HACCP system is theoretically sound in its design (Element 1), but also that the KEY QUESTION Question: Can an establishment's process use a different level of a critical operational parameter (for example, a higher concentration of an antimicrobial or a higher processing temperature) than what was used in the scientific or technical support? Answer: Generally, establishments should use the same critical operational parameters as those in the scientific or technical support. However, some minor differences are acceptable. For example, Table 1 of the Tompkin paper can be used to support a storage temperature CCP for raw meat of 45°F even though it cites 44.6°F as minimum growth temperature for Salmonella. This rounding is suitable because the growth rate of Salmonella at 45°F is not significantly different from its growth rate at 44.6°F. Furthermore, when temperatures are converted from Celsius to Fahrenheit, as in Table 1 of the Tompkin paper, numbers are often converted as fractions, which establishments may round to whole numbers because of practical measurement limitations of equipment in establishments. On the other hand, rounding may not be suitable for other critical operational parameters such as water

activity and pH because minor changes in the values can have a significant impact on pathogen growth. In some circumstances, establishments may be able to support using critical operational parameters (e.g., higher concentrations of antimicrobials or higher thermal processing temperatures) that are different from those in the scientific or technical support. In these cases, establishments should provide justification supporting that the levels chosen are at least as effective as those in the scientific or technical support. This justification is needed because higher levels of a critical operational parameter may not always be equally effective. For example, antimicrobial agents may only be effective within a range of concentration after which point efficacy may decrease. Similarly, higher processing temperatures may result in the surface of the product drying out before adequate lethality is achieved. In addition to ensuring that the levels chosen are at least equally as effective, establishments should ensure the levels are also safe and suitable (FSIS Directive 7120.1 Safe and Suitable Ingredients Used in the Production of Meat and Poultry Products and 9 CFR 424.21(c)). 20", "establishment can execute it as designed to reach the desired effect (Element 2). To meet the second element of validation, establishments should: \u2022 Implement the critical operational parameters in the actual production process consistent with the parameters in the scientific support; \u2022 Identify at least one product from each HACCP category for which to gather inplant validation data; \u2022 Collect in-plant data demonstrating the effectiveness of the implementation of the critical operational parameters for at least one product from each HACCP category; and \u2022 Analyze the data to determine whether the critical operational parameters are being implemented effectively. Once the critical operational parameters are identified, how should they be implemented in the actual process? Once the critical operational parameters are identified, an establishment should implement the critical operational parameters in the actual process consistent with the scientific support. If an establishment is using the scientific support as support for the development of a CCP and its critical limits (9 CFR 417.5(a)(2)) to prevent, reduce, or eliminate a hazard identified as RLTO, the establishment should incorporate all of the critical operational parameters into the critical limits of the CCP. An establishment may determine, however, based on its decision making, that some of the parameters can be monitored on an ongoing basis as part of a prerequisite program. An establishment may also determine that it only needs to ensure some of the critical operational parameters are implemented consistent with the support during the initial validation period (e.g., spatial configuration, equipment type to the extent that it affects other parameters, or ingredient formulation provided it does not change). These parameters should be included in a decision-making document, but they do not need to be monitored after the 90 days of initial validation unless there is a change. If an establishment is using the scientific support as support for a decision that a hazard is not reasonably likely to occur (9 CFR 417.5(a)(1) because the implementation of a prerequisite program prevents conditions that make the potential hazard likely, then all of the critical operational parameters should be incorporated into the prerequisite program. An establishment may also determine that it only needs to ensure some of the critical operational parameters are implemented consistent with the support during the initial validation period (e.g., spatial configuration, equipment type to the extent that it affects other parameters, or ingredient formulation provided it does not change). 21", "What types of data should establishments collect during the initial inplant validation period? Often establishments incorporate interventions into their processes to reduce the level of certain

pathogens and use published scientific articles as scientific support for the design of the interventions (see above discussion of the first part of validation). Establishments may implement those interventions consistent with the scientific support or make modifications to the critical operating parameters that could affect the efficacy of the intervention. To implement an intervention consistent with the scientific support means that changes among the critical operational parameters used in the scientific support and those used in the actual process will not affect the efficacy of the intervention or treatment. Depending on how an establishment implements the critical operational parameters for an intervention and the type of support used, different data should be collected during the initial in-plant validation period. These two scenarios are described below:

**Scenario 1** - In cases where the establishment's process is implemented consistent with the critical operational parameters described in the scientific support, and when the scientific support used contains microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, to meet the second element of validation, the establishment should:

- \uf0fc Identify the critical operating parameters in the scientific support, AND
- \uf0fc Implement those critical operational parameters in the establishment's production process consistent with the scientific support, AND
- \uf0fc Collect in-plant data that demonstrates that the critical operating parameters are being met (e.g., data on quantifiable characteristics of the critical operational parameters such as pressure, temperature, and concentration).

Thus, if an establishment implements the actual process consistent with the critical operational parameters in the scientific support, the establishment should collect in-plant data demonstrating that the critical operational parameters can all be met, and no in-plant microbiological data would be needed. For example, if the scientific support for a carcass wash intervention includes critical parameters of water pressure at the nozzle, water temperature at the point of contact with the carcass, whole carcass coverage, and a water\carcass contact time, then the establishment should measure and gather data on whether those parameters are being achieved. The water temperature measured in a holding tank or at the nozzle may not be the actual water temperature at point of contact with a carcass, so it is crucial to design measurement procedures appropriately.

**Scenario 2** - In cases where the establishment's process is not implemented in a manner that is consistent with the critical operational parameters described in the 22", "scientific support without justification, or when the scientific support used does not contain microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, to meet the second element of validation the establishment should:

- \uf0fc Identify the critical operating parameters in the actual process (either because they were modified from the scientific support without justification, or the scientific support does not contain microbiological data), AND
- \uf0fc Collect in-plant microbiological data that demonstrates the intervention's effectiveness under actual in-plant conditions or identify scientific support with microbiological data demonstrating the effectiveness of those critical operational parameters, \uf0fc AND
- \uf0fc Collect in-plant data that demonstrates that the modified critical operating parameters are being met.

Thus, if an establishment implements different critical operational parameters in the process from the scientific support, or if the scientific support does not contain microbiological data, then the establishment should collect in-plant data demonstrating the critical operational parameters

that it has implemented can all be met AND collect in-plant microbiological validation data or identify scientific support with microbiological data for the effectiveness of those implemented critical operational parameters. The establishment should develop the appropriate in-plant data during the initial 90 days of implementing a new HACCP system, or whenever a new or modified food safety hazard control is introduced into an existing HACCP system (e.g., as implemented after a HACCP plan reassessment). During these 90 calendar days, as described in the HACCP Final Rule, an establishment gathers the necessary in-plant data to demonstrate that the critical operating parameters are being achieved. In essence, the establishment would repeatedly test the adequacy of the process steps in the HACCP system to establish that the HACCP system meets the designed parameters and achieves the intended results. These in-plant data become part of the validation scientific support along with the scientific support used to design the HACCP system. See the section below on records for more information. Failure to take these steps would raise questions as to whether the HACCP system has been adequately validated. In addition to collecting the in-plant data described, it is critical that the establishment analyze the data to whether the critical operational parameters are being implemented effectively. This analysis should include a review of the records generated by the HACCP system during the initial validation period. Establishments may need to work with a statistician to conduct more in-depth statistical analyses of the in-plant data collected. For example, an establishment may need to work with a statistician to determine whether the in-plant validation data supports that it is implementing the critical operational parameters consistent with the scientific support. 23", "An establishment may also need to conduct more in-depth analysis if it implements critical operational parameters that are different from the process in the scientific support, and, as a result, it would need to collect in-plant microbiological data. For what types of processes and products should establishments collect in-plant validation data? Establishments should maintain scientific support for all processes and products; however, establishments should collect in-plant data for at least one product from each HACCP process category at that establishment. Depending on the HACCP category and products, establishments should consider collecting in-plant data for more than one product within each category. The object is to collect in-plant data for a wide variety of different products and worst case scenarios. Establishments should collect in-plant data for all CCPs and prerequisite programs used to support decisions in the hazard analysis for at least one product from each HACCP category at that establishment. Establishments should use food science principles in their decision making when deciding which product types within a HACCP category should be used to gather in-plant data. In addition, establishments should use decision-making documents to describe how the HACCP team decided on the product or product types that would be used during initial validation. Similarities and differences in species, process, intrinsic factors, product public health risk, and food safety hazards should be considered. Some examples of food science principles that could be used to decide which product within a HACCP category should be used to gather in-plant data include: \u2022 Fat content: Fat level in meat has been documented to influence bacterial heat resistance (Juneja et al., 2001). As the fat level increases, bacterial heat resistance increases. Therefore, higher fat content meat or poultry products require greater time or temperatures to achieve equal lethality compared with lower fat content products. o How this criterion could be used: If an establishment produces several fully cooked poultry products, the establishment should gather data for the product

with the highest fat content. Similarly, if an establishment produces several ground poultry products, and some of the products are made from skin-on thigh meat while others are made with boneless, skinless thigh meat, the establishment should collect in-plant validation data for the ground product made from the skin-on thigh meat because of the additional fat from the skin.

\u2022 Size and shape of the food: The size and shape of food affects heat penetration, heating rate, and heating uniformity. Irregularly shaped products, for example, are subjected to non-uniform heating because of differences in product thickness. In addition, in thicker products, more time will be needed for the heat to penetrate to the center of the product.

- o How this criterion could be used: If an establishment produces several fully cooked deli meat products of various thicknesses, the establishment should gather data on the thickest product because heat penetration is critical.

\u2022 Number and type of processing steps or ingredients: Certain processing steps, such as slicing of ready-to-eat product, are known to be potential sources of cross-contamination. In addition, some ingredients such as spices are known to introduce contamination (biological, chemical, or physical). Therefore, establishments should consider whether some products within a HACCP category undergo additional processing steps or contain additional ingredients that may introduce contamination and should collect in-plant validation data for that product.

- o How this criterion could be used: If an establishment fabricates beef manufacturing trimmings and uses the trimmings to produce ground beef and patties, the establishment should collect in-plant validation data for the patty process because the patty forming process introduces an additional step that could provide an opportunity for contamination.

\u2022 Product species: Studies have shown that there is a difference in bacterial resistance in products from different types of species. Therefore, establishments should consider collecting data separately for each species slaughtered or processed within a HACCP category.

- o How this criterion could be used: If an establishment slaughters hogs and cattle under one HACCP category, in-plant data should be gathered for both species because the slaughter process and the hazards associated with each are substantially different.

\u2022 Public health risk: Establishments should take past outbreaks into account when selecting a product to collect in-plant data for within a HACCP category.

- o How this criterion could be used: If an establishment produces several types of fully cooked ready-to-eat products, and one of the products is Lebanon bologna, data should be gathered for the Lebanon bologna because it was associated with an illness outbreak. In some cases, an establishment may produce products that are all of equal risk. In those cases, FSIS recommends that establishments select the product with the highest production volume because that product would have the greatest public exposure.
- o How this criterion could be used: If an establishment makes several types of fully cooked sausages and the only difference among these products are ingredients such as pimentos or pickles that are used as flavorings and that do not affect food safety, an establishment should gather data on the product produced in the highest volume. Finally, in other cases establishments may consider selecting more than one product from a HACCP category.

\u2022 For example: If an establishment processes both hot dogs and RTE whole turkey breast that is sliced, both products should be validated because their processes are substantially different, and both have been found to represent an increased risk of listeriosis illness to the consumer. How long does an establishment have to complete initial validation (Elements 1 and 2)? During the process of conducting a hazard analysis and developing a HACCP plan, establishments gather supporting documentation in the

form of scientific or technical support for the HACCP system design (Element 1). New establishments must conduct a hazard analysis (9 CFR 417.2) and develop and validate a HACCP plan (9 CFR 417.4) before being granted Federal inspection as required by 9 CFR 304.3(b) and 381.22(b). Additionally, establishments must conduct a hazard analysis and develop a HACCP plan (9 CFR 417.2) before producing a new product for distribution in commerce as required by 9 CFR 304.3(c) and 381.22(c). Consistent with these requirements, establishments should gather scientific or technical support for a modified HACCP plan before implementation, if the results of a reassessment indicate new or additional support is needed (e.g., if significant changes to an intervention are made or a new intervention is added). Establishments can begin gathering their support by conducting reviews of the available scientific literature, published processing guidelines, and regulatory performance standards to determine whether scientific documentation already exists matching their actual product and process. After the hazard analysis has been conducted, and the HACCP plan has been developed, establishments gather in-plant validation data proving that the HACCP system can perform as expected (Element 2). New establishments are issued a conditional grant of inspection for a period up to 90 days during which they must complete the initial validation as required in 9 CFR 304.3(b) and 381.22(b) (Element 2). Additionally, 9 CFR 304.3(c) and 381.22(c) require establishments producing a new product to complete the initial validation of the new HACCP plan during a period not to exceed 90 days after the date the new product is produced for distribution in commerce. Consistent with these requirements, initial validation should encompass the first 90 calendar days of an establishment's processing experience with a modified HACCP plan, if the results of a reassessment indicate in-plant validation data should be collected (e.g., if significant changes to an intervention are made or a new intervention is added). For large establishments, 90 calendar days equates to approximately 60 production days. FSIS recognizes that many small and very small establishments do not operate daily. Therefore, FSIS recommends a minimum level of records from 13 production days within those initial 90 calendar days should be used to initially validate a small or very small establishment's HACCP system. FSIS also recognizes that there are some establishments that produce products so infrequently that they would not be able to gather records from 13 production days within those 90 initial calendar days. If the establishment infrequently produces several products that are each part of a separate HACCP category, there is inherent risk with the processes if the establishment does not have experience in producing them. Therefore, to determine whether the system is "properly designed and executed, even though the regulations provide 90 days for initial validation, an establishment needing more than 90 days can ask the District Office, in writing, for additional time to collect at least 13 production days of records when it first starts operating, or when it begins producing new product, or for a modified HACCP plan if the results of a reassessment indicate additional support is needed. In the request, an establishment should indicate why more than 90 days are needed to collect the in-plant validation data, and how it plans to gather at least 13 production days worth of in-plant validation data within the next 30 calendar days. The request will then be evaluated on a case by case basis. The establishment should consider focusing validation activities on the product produced most frequently within each HACCP category. In addition, the establishment may consider evaluating data collected for products across multiple HACCP categories to determine whether the data together can support its ability to meet critical operational parameters. As

previously discussed, if an establishment implements a process consistent with the process specifications described in the scientific support, and the scientific support contains microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, the inplant validation data collected during the 90 day initial validation period will consist of data on quantifiable characteristics of the critical operational parameters, such as pressure, temperature, and concentration. However, if an establishment implements different critical operational parameters in the process from the scientific support, or the scientific support identified does not contain microbiological data, then the establishment should collect in-plant data demonstrating the critical operational parameters that it has implemented can all be met AND should collect in-plant microbiological validation data or identify scientific support with microbiological data that demonstrates the effectiveness of those implemented critical operational parameters. Establishments can continue producing and shipping product into commerce during the 90 day initial validation period with the exception of establishments that are gathering inplant microbiological data to support that a product is RTE. For example, if an establishment producing a RTE product is implementing a lethality process using different critical operational parameters (e.g., time, temperature, or relative humidity) from its scientific support, the establishment could commission a challenge study to demonstrate the effectiveness of the alternate parameters during the 90 day initial validation period. During this time, the establishment could not ship the RTE product into commerce because it does not have the necessary scientific support to demonstrate that all potential hazards have been addressed and that the product would meet the definition of RTE in 9 CFR 430.1 (that it is in a form that is edible without additional preparation to achieve food safety). If an establishment has questions as to whether complete scientific support is needed for its products before the products can be shipped into commerce, then it can submit a question through askFSIS at <http://askfsis.custhelp.com/> following the guidance on page ii of this document. 27", "What types of records are validation documents, and how long should an establishment keep them? The scientific support (design) and in-plant (execution) validation data support the decisions made in the hazard analysis and the adequacy of the process to control those hazards. Therefore, these supporting documents must be kept for the life of the plan to meet the requirements of 9 CFR 417.5(a)(1) & (2). NOTE: Establishments using existing HACCP systems developed before the issuance of this document that do not have the documents from their initial validation on file will need to gather the necessary data. Appendix 5 contains further guidance for establishments that no longer have the in-plant validation data. KEY QUESTION Question: If an establishment has not utilized a process for a year or more, is the process still validated? Answer: Most likely, no. An establishment would need to perform a reassessment in order to determine whether changes have occurred that could affect the hazard analysis or alter the HACCP plan. If the reassessment led to modifications in the HACCP system, then the establishment would need to gather additional in-plant validation data. Meat and poultry establishments must document each reassessment and the reasons for any changes to the HACCP plan based on the reassessment, or the reasons for not changing the HACCP plan based on the reassessment (9 CFR 417.4(a)(3)). For annual reassessments, if the establishment determines that no changes are needed to its HACCP plan, it is not required to document the basis for this determination. Key Requirement The scientific or technical support for the design

and initial in-plant execution validation documents must be kept on file as part of 9 CFR 417.5(a)(1) & (2) supporting documentation records. 28", "What is the difference between initial validation and on-going verification, and what happens after the initial validation period is over? Many agree that validation should be a distinct function from verification (see, e.g., Scott and Stevenson, 2006). During the 90 calendar days of initial validation following completion of the hazard analysis and development of the HACCP system, establishments check the validity or adequacy of the HACCP system. Establishments are to conduct validation activities during their initial experience with a new HACCP system. Establishments are required to complete the initial validation of the new HACCP plan in accordance with 9 CFR 417.4 during a period not to exceed 90 calendar days after the date the new process is used to produce product for distribution in commerce. During these 90 calendar days, an establishment gathers data from its monitoring and on-going verification activities at an increased frequency compared to the frequency listed in the HACCP plan and gathers additional data to demonstrate that the process is being executed effectively. During this period an establishment should be reviewing these data and making modifications to its system as necessary. NOTE: Establishments may determine that modifications are needed to an intervention during the initial validation period either because the design did not result in the intended effect or because the establishment could not execute the intervention as designed. Such modifications are part of the initial validation process. However, establishments that make major modifications multiple times throughout the initial validation period and as a result do not generate sufficient records that support the KEY QUESTION Question: If an establishment moves physical locations, will it have to repeat the in-plant documentation element of its initial validation? Answer: Most likely yes, as a result of the establishment\u2019s reassessment. Much like with large corporations with multiple establishments, the establishment will be able to transfer the scientific support from one location to another (meeting the first element of validation - design) but will most likely need to gather in-plant data to support the second element of validation (execution). There are often differences from location to location that may affect whether the critical operational parameters in the scientific or technical support can be implemented properly in the new establishment. For example, the same type of spray cabinet made by different manufacturers may have different flow rates for the intervention spray delivery that would require changes to other critical operational parameters in order to achieve equivalent application. The same may be true for the effect of employees or the size or shape of the physical location on the critical operational parameters. 29", "design and execution of the intervention used in the hazard analysis may not be able to support that the HACCP system is adequate. Following the 90 calendar day period of initial validation, an establishment uses its findings during the initial validation period to fully implement its system and solidify its monitoring and on-going verification procedures and frequencies. The establishment then continues on a daily basis to perform monitoring and verification activities to ensure that the HACCP system continues to be implemented properly. Establishments are required to support both the monitoring and verification procedures selected and the frequency of those procedures as part of 9 CFR 417.5(a)(2). Data gathered during initial validation, during which critical operational parameters are monitored at an intense frequency, is one source of information that can be used to support monitoring and verification procedures and frequencies (see examples in Appendix 4). Importantly, not all critical operational parameters

that are measured during initial validation are monitored on an ongoing basis after the initial validation period is over. For example, some parameters, such as spatial configuration or ingredient formulation, may not change over time and therefore do not need to be monitored. In addition, ongoing verification may include activities that were not performed as part of initial validation because the purposes of these two processes differ. The purpose of validation is to demonstrate that the HACCP system as designed can adequately control identified hazards to produce a safe, unadulterated product, while the purpose of ongoing verification is to support that the HACCP system is functioning as intended on an ongoing basis. Although it may be adequate to measure the critical operational parameters during initial validation to ensure that the HACCP system as designed can be executed, doing so does not negate the need for ongoing verification activities, such as testing for appropriate pathogens or other microorganisms, to support that the HACCP system is working as intended on an ongoing basis. In addition to continuing ongoing verification following the completion of the initial validation period, it is also important to recognize the role of reassessment in the process. At every reassessment, establishments should reassess the hazard analysis taking into account information on any foodborne illnesses associated with the products to determine whether all relevant hazards have been considered. In addition, establishments should ask: \u201cls my HACCP system adequate to control the identified food safety hazards?\u201d Annually and whenever changes occur that affect the hazard analysis, the establishment should review records generated over the course of the previous year, or during the period the change occurred, that reflect how the HACCP system is performing as a whole, and analyze them to determine whether food safety goals are being met. This review should include records of the monitoring of critical limits and parameters of prerequisite programs to ensure that the critical operational parameters in the scientific support continue to be met and any records from ongoing verification 30", "activities, such as microbiological testing, to ensure identified food safety hazards are being controlled. If the establishment determines at the end of the reassessment that the HACCP system is effective and functioning as intended, the establishment can continue on with the same system and the same monitoring and verification procedures and frequencies. If the establishment determines at the end of the reassessment that either its HACCP system was not set up correctly, is not being implemented consistently, or is no longer effective, the establishment should make changes to its HACCP system (e.g., add another intervention) and then would, in most cases, be required to validate any changes to its HACCP system. In some cases, however, changes that result from reassessment would not require validation. For example, an establishment that reassesses its HACCP system following a change in supplier of a raw material may find that the change does not require validation because the composition of the raw material and its microbiological profile are not significantly different from the material provided by the previous supplier. In other cases, changes that result from the reassessment would not require additional scientific support but would require additional in-plant validation data. For example, an establishment may find through reassessment that the design of an intervention was adequate, but that the employees were not implementing it correctly. In that case, the establishment would only need to collect in-plant validation data demonstrating the intervention could be implemented appropriately. Finally, depending on the change, the establishment will likely only need to validate that the change is functioning as intended and not assess the entire HACCP system. For example, an establishment may change the thickness

of a raw patty product and determine that it only needs to validate that the cooking instructions still achieve the desired endpoint temperature and does not need to validate the entire HACCP system. NOTE: Official establishments are to make a record of each reassessment required by 9 CFR 417.4(a)(3)(i). The regulations require establishments to document the reasons for any changes to the HACCP plan based on the reassessment or the reasons for not changing the HACCP plan based on the reassessment. For annual reassessments, according to the regulation, if an official establishment determines that it does not need to make changes to its HACCP plan, it is not required to document the reasons for not changing the HACCP plan. While the establishment is validating any changes it made to its HACCP system, the establishment continues to implement other parts of its HACCP system, such as any on-going verification activities, including testing that is done as part of its existing system. In other words, when an establishment makes changes to its existing HACCP If the establishment determines at the end of the reassessment that the HACCP system is effective and functioning as intended, the establishment can consider continuing on with the same system and the same monitoring and verification procedures and frequencies. 31", "system and is validating those changes, this validation does not occur in a vacuum. While microbiological testing is not required specifically as part of initial validation, other HACCP principles, such as on-going verification activities, continue to apply, including verification testing that is done to support that the HACCP system addresses identified hazards on an on-going basis. The following chart illustrates some of the key differences between initial validation and ongoing verification and shows the sequence of these key steps.

Initial Validation \u2022Frequency: \u2022Once over a period of the first 90 days of new or revised HACCP system \u2022Purpose: \u2022To ensure the HACCP system as designed functions as intended \u2022Process: \u2022Repeatedly test all critical operational parameters to show the establishment can implement them, and that they are effective at controlling the identified hazards

Ongoing Verification \u2022Frequency \u2022Ongoing following completion of initial validation (i.e., day 91) and onward

\u2022Purpose: \u2022To ensure the HACCP system is functioning as intended on an ongoing basis \u2022Process: \u2022Conducting ongoing verification activities including calibration, direct observation, and review of records as well as other independent checks such as testing

Reassessment \u2022Frequency \u2022Annually and whenever changes occur that affect the hazard analysis or HACCP plan \u2022Purpose: \u2022To determine whether the HACCP system as designed and executed is still adequate \u2022Process: \u2022Review of records generated from ongoing verification to ensure that the HACCP system as designed and executed is still adequate (i.e., through test results and monitoring of critical operational parameters) If reassessment results in no changes If reassessment results in changes to the HACCP system 32", "An example of the dynamic process illustrated earlier for a ground beef establishment is shown below. In this example, the establishment has decided to add an antimicrobial intervention to trimmings prior to grinding. Please note that the example only shows one part of the entire HACCP system.

Initial Validation \u2022During the first 90 days the establishment: \u2022Identified the scientific or technical support. \u2022Carpenter et al. 2011. Meat Sci: 88. \u2022Identified the critical operational parameters of the intervention \u2022Concentration: 2% lactic acid \u2022Dwell time: 20s \u2022Pressure: 20 psi

\u2022Temperature: 55\u00b0C \u2022Equipment: CHAD cabinet \u2022Complete coverage \u2022Demonstrated the critical operational parameters were met \u2022Trim Spray Cabinet

Worksheet was used to record critical operational parameters Ongoing Verification \u2022 On day 91 and onward the establishment chose to monitor the critical operational parameters as part of a CCP. \u2022 The establishment conducted ongoing verification activities related to the parameters being monitored including calibration, direct observation, and review of records. In addition the establishment, taking into account volume, chose to conduct ongoing verification testing of E. coli O157:H7 in trim on a quarterly basis. The establishment collected samples of trim after allowing the antimicrobial appropriate drip time and increased the frequency of testing during the high prevalence months. Reassessment \u2022 At the yearly reassessment the establishment evaluated the records generated during ongoing verification for the past year. Since there were no positives and the critical operational parameters of the intervention were consistently met, the establishment determined that the HACCP system is working as intended and will continue with conducting ongoing verification at the current frequency.

Reassessment resulted in no changes 33", "HACCP Initial Validation Self-Assessment Does my HACCP system: 1. Contain supporting documents for each CCP or prerequisite program that is used to support decisions in my hazard analysis? 2. Contain supporting documents that relate sufficiently to my product/process? 3. Identify the critical operating parameters based on the supporting documents used as scientific or technical support? 4. Contain critical operating parameters that are aligned with the referenced supporting document? 5. Contain critical operating parameters that support rather than contradict the selected critical operating parameter if multiple supporting references are used? 6. Contain in-plant validation data from 90 calendar days (see pages 26-27 for expectations regarding the equivalent number of production days) documenting the critical operating parameters are implemented for at least one product within each HACCP category? 7. Contain HACCP system in-plant validation data for at least one product within each HACCP category that was reviewed and found acceptable by the HACCP team to support that the process is validated by the HACCP team or other group responsible for food safety? 8. Contain additional research data demonstrating the effectiveness of the process in instances where the critical operational parameters from the support were not followed? For each HACCP category, identify at least one product from the category for which collect inplant demonstration data and complete a validation worksheet for such product containing the following information. Examples can be found in Appendix 4.

Product: Name the HACCP plan type or product category. Hazard: Name the hazard of concern. This should be the same content that is in the hazard analysis. Process: Name the processing step or prerequisite program that addresses the hazard. Critical Operating Parameters: Refers to the critical limits or other parameters cited in the scientific or technical support necessary for effective execution of the process step or program. Validation: Scientific or Technical Support - State the scientific or technical support document references and page numbers where the critical operating parameters are described. In-plant Validation Data - State the name of the monitoring documents or other records where observations were collected including the time frame. 34", "References FSIS. 1996. Following up on these results, FSIS conducted a review of Food Safety Assessments (FSAs) and onsite visits to veal slaughter establishments to identify concerns unique to veal slaughter. FSIS found that veal slaughter establishments, in applying their antimicrobial interventions, failed to achieve carcass coverage because of the practice of suspending carcasses from the rail system with both hind limbs on a single hook. Because of this practice, antimicrobial or hot water interventions, such as sprays, did not reach all parts of the carcasses. Carcass coverage \u2013ensuring that the entire carcass surface is treated -- is a critical operational parameter that is necessary for the intervention to operate effectively and as intended. As a result of the incomplete carcass coverage, interventions were likely less effective than intended, and this ineffectiveness may have contributed to the production of products contaminated with E. coli O157:H7. In addition, during on-site visits to beef fabrication establishments, FSIS found that beef fabrication establishments, in applying their antimicrobial intervention, had also failed to achieve product coverage because establishments stacked products and folded longer pieces, particularly loins. These actions prevented antimicrobial sprays from reaching all product surfaces. Additionally, establishment personnel did not adjust the conveyor belt timing, properly design spray applications, or ensure that product was singlestacked and lying flat so that all product surfaces received the antimicrobial spray. Validation Take-away: Had establishments translated this critical operational parameter \u2013 product coverage \u2013 into their HACCP system (either through a pre-requisite program, CCP, or during the initial set-up of their system) the contamination of raw beef products with E. coli O157:H7 and other STEC may have been prevented. 2011 \u2013 Lebanon Bologna E. coli O157:H7 Illness Outbreak In March 2011, there was a foodborne illness outbreak of E. coli O157:H7 associated with Lebanon bologna. The establishment that produced the product recalled it. An FSIS investigation into the processing of the product revealed that the establishment relied on scientific support that did not match the actual commercial process

used. In the scientific support, to represent a commercial process for Lebanon bologna, raw 36", "Lebanon bologna mix was compacted in 27 millimeter diameter impermeable sealed glass tubes that were immersed in a well-controlled water bath. However, in the actual process at the establishment, raw Lebanon bologna mix was compacted in 52 to 119 mm diameter permeable casings that were placed in a large smokehouse fitted with a single source of heat and humidity that was not well-controlled. The difference in the diameter and type of casing material likely led to a lower reduction in foodborne pathogens of concern in the actual process than what was demonstrated in the support. If the diameter of the establishment's product is larger than that of the product used in the support, it is possible that the product core will take longer to reach the desired temperature and pH. Taking a longer time than expected to reach the desired temperature and pH may lead to a lower level of pathogen reduction. Critical operational parameters such as the product diameter and type of casing material can also affect the amount of moisture exchange between the product and the environment and can play a role in the effectiveness of the fermentation. For these reasons, it is important that the support used by the establishment is representative of the establishment's actual process so that the results can be repeatable. Validation Take-away: Had the establishment ensured that its actual process matched its scientific support during the initial design of its system, the establishment could have addressed actual relative humidity and the time it took the actual product to reach the desired temperature and pH compared to that in the support, preventing product contamination and illnesses.

2007 \u2013 Chicken Pot Pie Salmonella Illness Outbreak and 2011 \u2013 Turkey Burger Salmonella Illness Outbreak In October 2007, a number of varieties of frozen pot pies were linked to an outbreak of salmonellosis. The establishment that produced the product recalled it. The pot pies contained pre-cooked poultry products but raw vegetables and dough. Testing of two of the pies taken from case patient homes found that the filling of the pot pies tested positive for Salmonella. An investigation revealed that the likely cause of illnesses was that consumers were not cooking the products in the microwave to a lethality temperature. Specifically, the investigation revealed that the instructions may have been confusing because different parts of the package recommended different preparation times. In addition, microwave time varied by wattage; however, most case patients interviewed did not know the wattage of their microwave. Other patients reported not following the microwave directions, including not following the rest time and microwaving more than one pie at a time. Therefore, one of the primary conclusions of the investigation was that the cooking instructions for such products should be validated to account for variability in microwave wattage and common misconceptions among consumers regarding the nature of not-ready-to-eat foods (<http://www.cdc.gov/mmwr/preview/mmwrhtml/mm5747a3.htm>). 37", "Between late December of 2010 and March of 2011, an outbreak of Salmonella Hadar linked to turkey burgers sickened 12 people, three of whom were hospitalized. Investigators were not able to determine consumption of turkey burgers for all casepatients. However, FSIS determined that at least three of the case-patients in three states specifically reported eating turkey burgers produced at the same establishment the week before their illness began. Samples of ground turkey burgers were collected by public health agencies from the homes of two case-patients who tested positive for the outbreak strain of Salmonella Hadar. Both turkey burger samples were positive for the outbreak strain. As a result of these findings, the establishment that

produced the product recalled 54,960 pounds of potentially contaminated product ([http://www.cdc.gov/salmonella/hadar0411/040411/index.html?s\\_cid=ccu041111\\_016](http://www.cdc.gov/salmonella/hadar0411/040411/index.html?s_cid=ccu041111_016)). In a post-outbreak investigation, FSIS found that the cooking instructions for the turkey burger were not sufficient to guarantee that a safe end-point temperature would be reached so that pathogens would be killed in the cooking process. Validation Take-away: Had the establishments validated the cooking instructions on the pot pies and turkey burgers to ensure they would achieve the desired end-point temperature under actual consumer cooking conditions; these illnesses may have been prevented.

38", "Appendix 2: Example Decision-making Document The following is an example of a decision-making document that could be used by a beef jerky processing establishment to justify using modified levels of critical operational parameters. In this case, the establishment has identified scientific support for its process; however, it has modified the critical operational parameters (length of cooking time and dry-bulb temperature during drying) in the actual process from those used in the scientific support. A rationale is provided for why the modified critical operational parameters should also be considered validated.

XYZ Meat Company - October 5, 2012 Beef Jerky Decision-Making Documentation Process Step: Cooking and Drying Process Step Overview: This process step includes the cooking and drying of beef jerky using a modified Type 1A process from Buege et al (2006). Scientific Support: \u2022 Critical limit summary for shelf stability of beef jerky and related products:[http://www.meathaccp.wisc.edu/validation/assets/CLSummary\\_WMJerkyleJune2013.pdf](http://www.meathaccp.wisc.edu/validation/assets/CLSummary_WMJerkyleJune2013.pdf). \u2022 Buege, D.R., Searls, G., and Ingham, S.C. 2006. Lethality of commercial wholemuscle beef jerky manufacturing processes against Salmonella Serovars and Escherichia coli O157:H7. J. Food Prot: 69(9): 2091-2099. Cooking and Drying Critical Operational Parameters: Stage 1 \u2013 170\u00b0F for 30 minutes. Stage 2 \u2013 Dry-bulb at 170\u00b0F and wet-bulb at 125\u00b0F for at least 90\* minutes Stage 3 - Dry at 175\u00b0F\* dry-bulb to doneness \*Rationale for Modified Critical Operational Parameters (those with an \*): The length of Stage 2 and the dry bulb temperature during Stage 3 were increased from what was studied in Buege et al. In Buege et al. the length of Stage 2 with a wet bulb of 125\u00b0F was 60 minutes, while the dry bulb temperature during Stage 3 was 170\u00b0F. As stated in the critical limit summary that goes along with the article: Type 1-A processes with a higher wet-bulb temperature or longer time in Stage 2, or a higher dry-bulb temperature in Stage 3, can also be considered validated as long as other parts of the process are not changed. So, these changes can also be considered validated.

39", "Appendix 3: Guidance to Identify Critical Operational Parameters from Scientific or Technical Support If a journal article from the scientific literature is used as the scientific support, it is important to understand how to read it and to identify the critical operational parameters used in the study. Researchers may measure a number of parameters during the scientific study; however, not all of these parameters are critical to the efficacy of the intervention studied. The establishment should document and explain any differences in its production process relative to any of the studies it used as scientific support. Critical operational parameters are those parameters of an intervention that must be met in order for the intervention to operate effectively and as intended. Typically critical parameters, identified in scientific documents gathered as part of Element 1 of validation, may include but are not limited to:

- \u2022 Time \u2022 Temperature \u2022 Concentration \u2022 Humidity \u2022 Dwell Time \u2022 Water Activity \u2022 pH \u2022 Contact Time \u2022 Product Coverage \u2022 Spatial Configuration \u2022 Pressure \u2022

**Equipment Settings or Calibration** The following discussion provides an overview of the sections of a journal article along with questions one can ask while reading each section to help identify the critical operating parameters in the scientific support.

**Organization of Journal Articles** In most scientific journals, scientific papers follow a standard format. Papers are divided into several sections, and each section serves a specific purpose. Common sections include the:

- \u2022 Abstract
- \u2022 Introduction
- \u2022 Materials & Methods
- \u2022 Results
- \u2022 Discussion
- \u2022 Conclusion

**Abstract** The paper begins with a short summary or abstract. Generally, the abstract gives a brief background to the topic, describes concisely the major findings of the paper, and relates these findings to the field of study.

**Introduction** This section presents the background necessary for the reader to understand why the findings of the paper are an advance on the knowledge in the field of study. Typically, the introduction:

- First, describes the accepted state of knowledge in a specialized field.
- Then, focuses more specifically on a particular aspect, usually describing a finding or a set of findings that led to the work described in the paper (i.e. objective or rationale).

**Materials & Methods** In some journals, this section is the last one but not in most food science-related journals. Its purpose is to describe the materials used in the experiments and the methods by which the experiments were carried out. When reading the abstract, first consider and review what you know about the topic. Discuss the study within the HACCP Team and gain an understanding of how you can apply the study in your HACCP decision making.

Questions to ask when reading the Materials & Methods:

- What food products did the researchers study?
- How similar are the products to the ones you are processing?
- If a product's characteristics were provided (i.e., % salt, fat, moisture, etc.), how similar are they to your product?
- What hazards did the researchers study? Are they the same hazards you have identified in your hazard analysis?
- Or did they study surrogates or indicator organisms only?
- Can you identify which operational parameters were measured? For example:
  - pH of the product;
  - Temperature of the product or carcass;
  - Temperature of the laboratory and/or processing facility;
  - Pressure or temperature at which that wash or antimicrobial was applied;
  - Length of time intervention was applied for.
- Where in the process or on the product were the measurements taken?
- Is your establishment taking measurements in these locations?
- What parameters, if any, were held constant across experimental conditions?
- What parameters, if any, were varied or changed in the research? Although some parameters may or may not have been experimentally manipulated, they are all important and their impact on the effectiveness on the intervention should be considered.

Note that some measured parameters in a study are not related to the efficacy of interventions and are not, therefore, critical operational parameters.

**Results** This section describes the experiments and documents the experiment outcomes.

**Discussion** In some journals the Results & Discussion section may be combined. When the discussion section is a stand-alone section it usually serves several purposes:

- Analyzing and interpreting the data in the results section.
- Explaining how the findings relate to other findings in the field of study.
- Explaining how the findings contribute to knowledge or correct errors of previous work.
- Sometimes provides guidance on appropriate applications of the research.

**Conclusion** This section summarizes key findings.

Often includes implications of research for broader field.

\u2022 May highlight limitations of the study. Figures & Tables \u2022 Contain the data described in the paper. \u2022 Give details of a particular experiment or experiments conducted. \u2022 The \u201cmeat\u201d of the article. Questions to ask when reading the Discussion: \u2022 Did the authors provide some guidelines as to the limitations of the research or any cautions against applying the findings outside of the scope of the study? o For example, were there some parameters that were controlled in the laboratory that differ in-plant that you should be aware of? o If so, have you considered if those apply to your process? 42", "For Illustration Purposes Only Appendix 4: Validation Worksheet Examples The following pages include validation worksheet examples that can be used to help an establishment understand the types of scientific support and in-plant documentation that are needed to comply with the validation requirements. Please note that these are only examples. Each establishment will have to identify scientific support that closely matches its process and identify and implement the critical operational parameters in the support. Depending on the support chosen, different critical operational parameters may be identified. In addition, mention of trademarks or commercial names does not constitute endorsement by USDA. 43", "For Illustration Purposes Only Product Hazard Process Critical Operational Parameters2 Validation Scientific or Technical Support In-Plant Validation Data Poultry Carcass Biological - Salmonella Final Chiller Dilution of 15% peracetic acid\10% hydrogen peroxide mixture (PAHP) to a final concentration of 85 ppm peracetic acid in chiller; exposure in chiller for 20 minutes; pH = 4.5; complete carcass coverage Bauermeister, L.J., J.W.J. Bowers, J.C. Townsend, and S.R. McKee. 2008. Validating the Efficacy of Peracetic Acid Mixture as an Antimicrobial in Poultry Chillers. J. Food Prot. 71(6): 11191122. Food and Drug Administration Environmental Decision Memo for Food Contact Notification No. 000323: April 10, 2003 FSIS Directive 7120.1 Safe and Suitable Ingredients used in the Production of Meat, Poultry, and Egg Products In plant monitoring records for 90 day period recorded on Final Chiller Monitoring Check Sheet (including PAHP concentration, estimation of exposure time, pH, and carcass coverage); Trial report showing consistent operational parameters and microbial analysis, if possible, for 90 days. 2 Refers to the critical limit or other parameter cited in the scientific support necessary for effective execution of the intervention. 44", "For Illustration Purposes Only Product Hazard Process Critical Operational Parameters Validation Scientific or Technical Support In-Plant Validation Data Poultry Carcass Biological Salmonella Spraying of carcasses with peroxyacetic acid prior to chiller 25-230 ppm of peracetic acid (PAA). Pressure or flow rate, pH, contact time, and complete carcass coverage specified in challenge study. Challenge study from \u201cXYZ\u201d laboratory demonstrating a 1 log reduction Salmonella on poultry carcasses after spraying with PAA using critical operational parameters specified. Food and Drug Administration Environmental Decision Memo for Food Contact Notification No. 000323: April 10, 2003. FSIS No Objection Letter for Use of PAA spray, June 12, 2007 on file with company \u201cABC\u201d. FSIS Directive 7120.1 In plant monitoring records for 90 day period confirm that antimicrobial solution was applied consistent with the critical operational parameters (pressure, pH, contact time, and carcass coverage)in the study. 45", "For Illustration Purposes Only Product Hazard Process Critical Operational Parameters Validation Scientific or Technical Support In-Plant Validation Data Poultry parts intended for grinding and ground poultry (including mechanically separated poultry) Biological Salmonella Acidified sodium chlorite applied to poultry parts as a dip prior to grinding and applied to ground poultry. 1200 ppm

acidified sodium chlorite in combination with any GRAS acid at a level sufficient to achieve a pH of 2.5 in accordance with 21 CFR 173.325 and scientific support (Note: The pH depends on the application, see 21 CFR 173.325) Contact time of dip and complete coverage. Chemical manufacturer's pamphlet demonstrating a 1-log<sub>10</sub> reduction Salmonella on poultry parts following acidified sodium chlorite dip using critical operational parameters specified. 21 CFR 173.325 for poultry parts and acceptability determination for ground poultry. FSIS Directive 7120.1 In plant monitoring records for 90 day period that indicate the antimicrobial was applied to the poultry parts prior to grinding and the mechanically separated poultry prior to mixing according to the appropriate concentration and pH and that indicate contact time and complete coverage were achieved according to scientific support. 46", "For Illustration Purposes Only Product Hazard Process Critical Operational Parameters Validation Scientific or Technical Support In-Plant Validation Data Ground Poultry Patties Biological Salmonella Validated cooking instructions for consumers Time and temperature combinations specific to various cooking methods (skillet on electric stove, skillet on gas stove, gas grill, charcoal grill), diameter and thickness of patties produced, formulation of patties produced (80% lean patties vs. 95% lean patties), and state of patties during cooking (frozen and thawed). Food Safety Inspection Service. 1999. Appendix A of the Compliance Guidelines for meeting Lethality Performance Standards for Certain Meat and Poultry Products. Available at: <http://www.fsis.usda.gov/wps/wcm/connect/212e40b3b59d-43aa-882ee5431ea7035f/95033Fa.pdf?MOD=AJPERES>. Cooking trials on-file supporting the timetemperature combination selected from Appendix A can be achieved using various cooking instructions provided on the label. Cooking trials should be for the thickest and largest diameter patties produced as these will need the greatest time to achieve the desired endpoint temperature. In plant monitoring records for 90 day period that demonstrate establishment produces products that are of the thickness, diameter, fat level, and state for which the instructions are validated. 47", "For Illustration Purposes Only Product Hazard Process Critical Operational Parameters Validation Scientific or Technical Support In-Plant Validation Data Hog Carcass Biological Salmonella Hot Lactic Acid Spray Cabinet A least a 2% Lactic acid solution at 131°F (55°C) for more than 60 seconds and 13-23 psi. Complete carcass coverage. Van Netten. P., D.A.A. Mossel, and J. Huis In't Veld. 1995 Lactic acid decontamination of fresh pork carcasses: a pilot plant study. Int. J. Food Micro. 5: 1-9. In plant monitoring records for 90 day period indicating a minimum internal temperature of  $130^{\circ}\text{F}$  for 112 minutes is achieved. In plant monitoring records for 90 day period demonstrating use of dry and wet bulb thermometers to calculate the relative humidity or use of a humidity sensor to measure relative humidity during cooking. Records should indicate that humidity can be maintained >90% for at least 25% of the cooking time and in no case less than one hour by use of steam injection for 90 days. 63", "Appendix 5: Guidance for Establishments that No Longer Have the In-Plant Validation Data FSIS realizes that some establishments may not have kept their initial in-plant validation data from when HACCP was originally implemented. These documents for example would generally include 90 days of production records and any additional data gathered to demonstrate the establishment is able to effectively execute the critical operating parameters of their system as described below. Those establishments that have not kept the records will be allowed the time to assemble their in-plant validation data. For large establishments, FSIS will wait until January 4, 2016 before including verification that establishments have complied with the second element of validation (inplant validation data) as part of its inspection activities. Thus, large establishments will have six months to gather all necessary in-plant validation documents. Small and very small establishments will have until April 4, 2016 gather all necessary inplant validation data before FSIS will verify and enforce the second element of validation (in-plant validation data). Such documents may include HACCP records that are already generated as part of the monitoring of

critical limits or parameters of prerequisite programs. Examples of documents that can be used by existing establishments that no longer have in-plant validation data include: \u2022 HACCP records collected during 90 days when the current HACCP system is in operation. \u2022 Decision-making documents related to CCPs and critical operational parameters data gathering methods. \u2022 Records associated with initial equipment set up or calibration that contain data on additional critical operational parameters that did not become CCPs to support that the parameters were met during the initial set-up. \u2022 Any establishment sampling results for the product and process of interest. Establishments should review such in-plant validation data already being collected to ensure that they continue to support that the critical operational parameters identified in the scientific documentation are being met. If these documents do not address all of the critical operational parameters identified in the scientific or technical support, then additional data may need to be generated to demonstrate that those parameters can be properly implemented. Establishments may also wish to use the HACCP Initial Validation Self-assessment provided on Page 34 as a check to ensure that the HACCP system was designed correctly the first time.

Future editions will continue to reflect feedback received from all stakeholders."}]

represents FSIS\u2019s current thinking on this topic and should be considered usable as of this issuance. Therefore, FSIS encourages establishments slaughtering or producing raw poultry products to incorporate information in this guideline in their decision making process. A final version of this guidance will be issued in response to public comments. The information in this compliance guideline is provided as guidance to assist poultry slaughter establishments, and is not legally binding from a regulatory perspective. What is the purpose of this Compliance Guideline? The purpose of this guidance document is to help small and very small poultry slaughter establishments comply with the new microbiological sampling and analysis requirements that apply to all official poultry slaughter establishments, except for establishments that slaughter ratites (79 FR 49566). Establishments may also find the references listed at the end of this document useful for further resources as well as background on technical concepts. Note that establishments can also seek guidance from University Extension Service specialists within the state that the establishment is located on how to design sampling plans, how to collect samples, and how to test raw poultry products. How can I comment on this Compliance Guideline? FSIS is seeking comments on this guidance document as part of its efforts to continuously assess and improve the effectiveness of policy documents. All interested persons may submit comments regarding any aspect of this document, including but not limited to: content, readability, applicability, and accessibility. The comment period will be 60 days and the document will be updated in response to the comments received.

Comments may be submitted by either of the following methods:

- 3", "Federal eRulemaking Portal: This Web site provides the ability to type short comments directly into the comment field on this Web page or attach a file for lengthier comments. Go to regulations.gov and follow the online instructions at that site for submitting comments.
- Mail, including CD-ROMs, and hand - or courier-delivered submittals: Send to Docket Clerk, U.S. Department of Agriculture (USDA), FSIS, OPPD, RIMD, Patriots Plaza 3, 1400 Independence Avenue SW, Mailstop 3782, Room 8-163A, Washington, DC 20250-3700. All items submitted by mail or electronic mail must include the Agency name and docket number FSIS\u2019s ability to maintain process control for prevention of contamination with enteric pathogens (e.g., *Salmonella* and *Campylobacter*) and fecal material. Under the new rule, establishments must incorporate their written procedures, including their microbiological sampling plans, into their Hazard Analysis and Critical Control Points (HACCP) plans or Sanitation Standard Operating Procedures (Sanitation SOP) or other prerequisite program. Because this sampling and analysis is part of the procedures to prevent contamination by enteric pathogens and fecal material, the establishment needs to be able to support that the results relate to prevention of enteric pathogens and contamination by fecal material throughout the slaughter and dressing operation. The new recordkeeping and sampling

requirements in 9 CFR 381.65(g) are applicable to poultry establishments that slaughter poultry under any of the exemptions based on religious dietary laws in 9 CFR 381.11 through 9 CFR 381.14 (Confucian, Buddhist, Islamic, or Kosher). Establishments that slaughter multiple classes of poultry, other than ratites, may test the type of poultry slaughtered in the greatest number to meet the requirements in 9 CFR 381.65(g). However, these establishments are required to have written procedures to prevent enteric pathogen and fecal contamination throughout slaughter and dressing process to address all species slaughtered at the establishment.

Establishments that slaughter poultry other than ratites are responsible for determining which microbial organisms will be most effective in monitoring process control for enteric pathogens and fecal contamination and in supporting their sampling plan. Establishments are required to have a supportable sampling plan, including sampling frequency, microbes for which there will be analysis, and, where appropriate and practical, acceptable microbiological levels. FSIS recommends that establishments conduct baseline sampling periods during which they map the various points in the slaughter operation that could impact microbial and fecal contamination. This baseline sampling and mapping should occur at some regular, defined interval (e.g., seasonally or annually). Such sampling can be used to determine the frequency of testing and set the microbiological levels that are needed to ensure that the food safety system is in control. The regulations prescribe the minimum requirements for the location and frequency of sampling, based on establishment size and production volume. The microbial testing program may include indicator organisms, enteric pathogens, or both collectively to 5", "meet the minimum sampling frequency requirements. Establishments may combine these sampling data into one sampling program and make process control decisions based on a collective analysis of these data. As FSIS stated in the final rule, \u201cFSIS considers the microbial characteristics of poultry carcasses at pre-chill to be a valuable source of data about how well an establishment is minimizing contamination with enteric pathogens and fecal material on live birds coming to slaughter and on carcasses throughout the evisceration and dressing process. FSIS considers the microbial characteristics of poultry carcasses post-chill to be a valuable source of data about how well an establishment is minimizing contamination during chilling and the overall effectiveness of any antimicrobial interventions the establishment has chosen to apply throughout its process. Because most establishments apply one or more antimicrobial interventions between the pre- and post-chill sampling points to help control microbiological hazards, FSIS would expect that a reduction in microbiological contamination between these two points to be an indication of the effectiveness of those controls.\u201d (79 FR 49602). Therefore, with an exception for very small and very low volume (VLV) establishments operating under the Traditional Inspection System, poultry slaughter establishments are required to collect samples for microbial analysis at the pre-chill and post-chill locations to monitor for process control. Establishments may integrate existing sampling programs, such as programs that were part of the Salmonella Initiative Program (SIP), to develop one comprehensive sampling program. Such a program could include microbiological sampling from process mapping or other programs that met requirements in previous generic E. coli requirements. This program could be acceptable provided that the total number of samples collected and analyzed at pre-chill and post chill is at least equal to the minimum number of samples required in the regulation. These programs could also include sampling of more than one microbe. The written plan should describe how the establishment

intends to analyze the data and to make process control determinations. Although an establishment is not required to routinely test for enteric pathogens (e.g., *Salmonella* and *Campylobacter*), it should maintain data on file to support why the indicator organism it has selected to monitor process control is representative of process control for enteric pathogens, and that it is reaffirming this relationship on a recurring basis (e.g., at least once per quarter). There are no identified index organisms that directly reflect the presence or absence of enteric pathogens in poultry (e.g., *Salmonella* and *Campylobacter*). Therefore, FSIS recommends that an establishment test for enteric pathogens at least intermittently and compare its results against the presence or absence of other non-pathogenic organisms (i.e., the indicator organisms the establishment is using) to assess whether it is maintaining process control. An establishment's program for preventing contamination of carcasses and parts by enteric pathogens and fecal material needs to address all edible products, including whole carcasses, reprocessed carcasses, and parts, produced during the slaughter process. The establishment must include in its design the frequency and location of sampling within its process and which microorganisms to test for to demonstrate process control in preventing contamination of carcasses and parts by enteric pathogens and fecal material. FSIS has defined very small establishments operating under Traditional Inspection and VLV establishments operating under Traditional Inspection below. These establishments must collect samples for microbial organisms at the post-chill point in the process. In addition, VLV establishments must collect and analyze samples at least once during each week of operation starting June 1 of every year. If, after consecutively collecting 13 weekly samples, a VLV establishment can demonstrate that it is effectively maintaining process control, it may modify its sampling plan. For example, after collecting 13 weekly samples, a VLV establishment could collect samples less frequently, such as once a month, and use visual observation and documentation at control points to monitor process control. In this case, the establishment would need to document the changes and maintain documentation showing that the changes allow the establishment to continue to effectively monitor process control. Additionally, the establishment should identify in a written document conditions that would indicate that there is a failure in its process that requires a return to the higher level of sampling until the source is identified and effectively corrected. All other establishments are required to collect and analyze a pair of samples - one sample at pre-chill and one sample at post-chill - at the following minimum frequency: Chickens: once per 22,000 carcasses but at a minimum of once during each week of operation; and turkeys, ducks, geese, guineas, and squabs: once per 3,000 carcasses but at a minimum once each week of operation. Table 1. Establishment Size, Sampling Frequency and Sampling Location Requirements Establishment size Defined as Minimum sampling location Minimum sampling event frequency Very low volume (VLV) Slaughter no more than 440,000 chickens, 60,000 turkeys, 60,000 ducks, 60,000 geese, 60,000 guineas, or 60,000 squabs annually A sample at post-chill per sampling event At least once during each week of operation, starting June 1 of every year. If, after consecutively collecting 13 weekly samples and upon demonstrating effective process control, the sampling plan may be modified. Very small (VS) Fewer than 10 employees or annual sales of less than \$2.5 million. A sample at post-chill per sampling event Chickens: once per 22,000 carcasses, but at a minimum of once during each week of operation. Turkeys, ducks, geese, guineas, and squabs: once per 3,000 carcasses 7", "Small 10 \u2013 499 employees unless annual sales total less than \$2.5 million A sample at

pre-chill and a sample at post-chill locations per sampling event but at a minimum once each week of operation. Large 500 or more employees The effective date of these requirements for establishments was as follows: \u2022 Large establishments: November 19, 2014; \u2022 Small establishments: December 19, 2014; and \u2022 VS and VLV establishments: February 17, 2015. To provide additional clarification to help establishments meet these sampling requirements, FSIS is providing information concerning how to determine the necessary number of samples on an annual basis. An establishment (other than a VLV slaughter establishment that needs to sample at the minimum frequency specified above) can determine the total number of samples that it would need to collect on a given production day based on its annual production volume over the previous calendar year divided by the total number of production days within the same calendar year. The establishment would then determine the distribution of total number of samples over the total number of production days. An establishment should consider seasonal increases in production over the calendar year when allocating how many sampling events need to take place on any given production day or production period. For example, many turkey slaughter establishments traditionally experience a seasonal increase in slaughter production volume during the later months of the year. To support their sampling frequency, establishments need to consider this seasonal increase in slaughter volume. Establishments may determine that they need to increase the number of samples collected on production days during this period as compared to other times of the year. This increase would provide increased assurance that testing data will be sufficient to inform the establishment of its process control during these periods of higher production volume. These determinations are required to be in decision making documents that support the establishment\u2019s sampling frequency. An establishment may choose to sample parts (e.g., wings, legs) rather than carcasses to meet the requirements under 9 CFR 381.65(g)(2). If an establishment chooses to do so, the establishment is required to maintain data that demonstrates that its process is preventing contamination of carcasses and parts by enteric pathogens and fecal material throughout the entire slaughter process. The establishment is also required to maintain data that demonstrates that the sampling of parts at pre-chill and post-chill is representative of results that would be observed with sampling of whole carcasses at pre-chill and post-chill locations. The establishment should verify this association at some frequency (e.g., annually). 8", "Statistical Process Control and Indicator Organisms Statistical process control provides a powerful mechanism for establishments to monitor and interpret the data collected for ongoing HACCP verification. Statistical process control can provide establishments with an early warning that their process may not be functioning as designed. This warning can allow establishments to take corrective actions or make other process modifications to bring their process back into control without actually failing the individual establishment-identified pre-determined performance criteria. Statistical process control can also provide establishments with reasonable assurance that their HACCP system is functioning as designed, and that they are likely to meet applicable establishment-identified performance criteria. A number of methods and approaches are available for establishments to follow. Establishments should consider available guidance and develop a statistically valid approach for interpreting sample results (Saini et al. 2011; De Vries and Reneau 2010). In cases where an establishment does not have the resources or capacity to conduct baseline sampling that would be used to develop and implement their own statistical control limits or procedures,

establishments can utilize the results from FSIS nationwide poultry surveys, provided in Tables 2 (chicken) and 3 (turkey). As the establishment continues to collect its own data, FSIS recommends that the establishment consider these data to modify their statistical process control parameters to be more useful within their own establishment. The results in Tables 2 and 3 come from nationwide surveys conducted between 2007 and 2012<sup>1</sup>. During these surveys, FSIS collected samples from multiple points during processing; both chicken and turkey carcasses at rehang; and post chill. In these studies, FSIS sampled chicken by rinsing the carcass with 400 mL of solution and turkeys by swabbing two 50 cm<sup>2</sup> areas on the carcass. The tables show the median enumeration values for four common indicator bacteria: generic E. coli, APC, Enterobacteriaceae, and total coliforms. The median indicates that 50% of the samples in the FSIS surveys had enumeration values below the ones in the table, and 50% had values above the ones in the table.

Table 2 - Indicator Organism Median Values for Chickens Median (CFU\mL) Generic E. coli APC Enterobacteriaceae Total Coliform Carcass \u2013 Rehang 540 28,000 1,600 940 Carcass \u2013 Post Chill 20 260 20 20 1 FSIS Young Chicken Survey; FSIS Young Turkey Survey. 9", "Table 3 - Indicator Organism Median Values for Turkeys Median (CFU\mL) Generic E. coli APC Enterobacteriaceae Total Coliform Carcass \u2013 Rehang 22 1,800 50 40 Carcass \u2013 Post Chill <1.2 18 <1.2 <1.2 If an establishment uses the data from these tables, it is important that its sampling methodology (i.e., amount of solution to rinse the chicken carcass) be comparable to the FSIS method. When establishments compare their sample results to the ones in the table, a sample value that is higher than the corresponding one listed in the table indicates that the establishment may not be maintaining process control and may be less likely to meet the applicable performance criteria. Sample values lower than the one listed in the table indicate that the establishment is maintaining process control unless there is evidence that there are other problems in the establishment\u2019s procedures or production environment, such as evidence that the establishment\u2019s product has been associated with illnesses. When illnesses are associated with a particular establishment, achievement of a lower frequency of contamination, along with a lower level of contamination, has been demonstrated to be essential in reducing or eliminating illness from the establishment\u2019s products and protecting public health. Very small and VLV slaughter establishments operating under Traditional Inspection can choose to continue to conduct generic E. coli testing at post-chill to meet these requirements. FSIS considers the requirements under the former regulations for generic E. coli testing of poultry to be a scientifically validated \u201csafe harbor\u201d for monitoring process control specifically for fecal contamination. However, an establishment may choose to perform additional testing to monitor for process control of enteric pathogens to meet the new regulatory requirements. Former provisions that FSIS considers to be safe harbors:

- A. Each very small or VLV establishments that slaughters poultry under Traditional Inspection may test for Escherichia coli Biotype I (also referred to as generic E. coli) at the post-chill point in the process.
- B. To collect the sample, the establishment should collect a whole bird from the end of the chilling process. If this is impracticable, the whole bird can be taken from the end of the slaughter line. The sample is collected by rinsing the whole carcass in an amount of buffer appropriate for that type of bird. Samples from turkeys may also be collected by sponging the carcass on the back and thigh.

10", "C. Laboratories analyzing the samples should use any quantitative method for analysis of generic E. coli that is validated by a recognized independent testing body and based on the results of a

collaborative trial conducted in accordance with an internationally recognized protocol on collaborative trials and compared against the three tube Most Probable Number (MPN) method and agreeing with the 95 percent upper and lower confidence limit of the appropriate MPN index. D. An establishment is operating within the criteria when the most recent E. coli test result does not exceed the upper limit (M), and the number of samples, if any, testing positive at levels above (m) is three or fewer out of the most recent 13 samples (n) taken as in Table 4 below. For classes of poultry that do not have established M and m values, an establishment can use Statistical Process Control to determine its upper and lower control limits: Table 4 \u2013 Upper and Lower Limits for Generic E. coli testing in Chickens Type of poultry Lower limit of marginal range (m) Upper limit of marginal range (M) Number of Samples tested (n) Maximum number permitted in the Marginal range Chickens 100 cfu/ml 1,000 cfu/ml 13 3 Written microbiological sampling program The following elements should be included in the written sampling program: 1. A description of the sample collection procedures, including how random sampling is achieved, how the sample is taken, and how samples are handled to ensure sample integrity; and the name or title of the establishment employees designated to collect the samples for testing. 2. Information on the analytical method used to analyze the samples and identify the laboratory performing the analysis. The method used should be validated by a recognized independent testing body. 3. The microbiological organisms (i.e., *Salmonella*, *Campylobacter*, or indicator organisms, such as aerobic plate count (APC), total coliform, *Enterobacteriaceae*, and generic E. coli) that it will test for to monitor the effectiveness of its process control procedures. 11", "4. The locations within the process where samples are collected. Establishments, except for very small establishments or VLV establishments operating under Traditional Inspection, must collect samples at pre-chill and post-chill points in their process (9 CFR 381.65(g)(1)). Very small establishments or VLV establishments operating under Traditional Inspection must collect samples at post -chill point in their process. 5. The frequency of sample collection (9 CFR 381.65(g)(2)) (See Table 1). 6. Scientific and technical documentation to support the design of the sampling program. Further information on scientific and technical documentation can be found in the FSIS Compliance Guideline: HACCP Systems Validation, May 2013. The Appendix on page 25 contains a self-assessment checklist that highlights the key elements that an establishment should address as part of their written microbiological sampling program. Random selection of carcasses Samples should be collected randomly at the frequency determined by the establishment as part of its sampling plan. At a minimum, the establishment must collect samples at the frequency specified under 9 CFR 381.65(g)(2). If more than one shift is operating at the establishment, the sample can be taken on any shift provided there are samples collected from all shifts randomly over time, and there are not notable differences in the outcome. Different methods of selecting the specific carcass for sampling could be used, but the method used should include the use of random numbers to ensure that testing data are not biased. Examples of methods include random number tables, calculator or computer-generated random numbers, or drawing cards. The carcass that is sampled should be selected at random from all eligible carcasses and should include reconditioned, trimmed and reprocessed whole carcasses as well as \u201cmajor portions\u201d since these carcasses can be a significant source of redistribution of contamination prior to chilling. If there are multiple lines or chillers, randomly select the line or chiller for sample collection for that interval. Each line or chiller should have an Definitions Pre-

chill: a point in the slaughter process between and including rehang and just prior to the carcass entering the chiller. Allow appropriate drip time after interventions before collecting sample.

Post-chill: a point in the slaughter process after the carcass exits the chiller and after all slaughter interventions are completed, which is the same point in the process that FSIS collects samples for *Salmonella* and *Campylobacter* verification testing. If water immersion chilling is used, allow appropriate drip time before collecting the sample. 12", "equal chance of being selected at each sampling interval within the relevant time frame (based on the sampling frequency for the establishment). Carcasses should be selected at the identified points in the process (pre- and post- chill). At the post-chill site, samples should be collected after the final wash and the application of any final antimicrobial interventions. A drip time of at least 60 seconds should be observed before sample collection to prevent excessive antimicrobial carryover in the collected sample. A longer drip time prior to sample collection may better ensure that the technical effect of the antimicrobial treatment is neutralized. Establishments should seek guidance from the manufacturer of the antimicrobial treatment as to the optimal drip time and process to counter adverse outcomes of the treatment. Pre-sampling preparation and aseptic technique Extraneous organisms from hands, clothing, sampling equipment, or the processing environment may contaminate samples and lead to erroneous analytical results.

Aseptic sampling techniques should be followed to ensure accurate results that are representative of the product and process. Before beginning sample collection, it is important to assemble sampling supplies, such as sterile gloves, sterile sampling solutions, and sanitizing solution. Sterile sampling solutions, such as Butterfield's phosphate diluent (BPD) or buffered peptone water (BPW), should be stored according to the manufacturer\u2019s instruction at room temperature; however, at least the day before sample collection, check such solutions for cloudiness and do not use solutions that are cloudy or turbid or that contain particulate matter. An area should be designated as a staging site for preparing the sampling supplies. A sanitizable surface, such as a stainless steel table or wheeled cart, can be used. A small plastic tote may also be useful for transporting sampling supplies to sample collection sites. Sterile gloves should be used when handling carcasses or sterile sampling equipment (e.g., sampling sponge) during the sample collection process. Care should be taken to prevent contamination of the external surface of the gloves prior to or during the sample collection process. Step-by step instructions on aseptic gloving are included as an attachment to this document (Attachment 1).

13", "Examples of non-destructive sample collection techniques that an establishment may choose to use to collect samples are included as attachments to this document. The methods describe a nondestructive sponge technique for sample collection from turkeys and a whole bird rinse technique for sample collection from chickens (Attachments 2 and 3). Sample analysis To obtain the most accurate results, samples should be analyzed as soon after collection as possible. If samples must be transported to an off-site laboratory, they should be refrigerated and then shipped refrigerated, on the same day they were collected, via an overnight delivery or courier service to the laboratory. NOTE: *Campylobacter* is particularly sensitive to freezing conditions. Thus, frozen samples may significantly underestimate whether this pathogen was present in the unfrozen sample. Multiple samples collected on the same day can be shipped together to the laboratory in the sample shipping container. A sample should arrive at the laboratory and be analyzed no later than the day after it is collected. If sample collection, pick-up or shipment, and laboratory analysis cannot be carried out within this timeframe, the

carcass or product selected for sampling should be held under refrigeration until the process can be accomplished in the appropriate span of time. The same principle applies for samples that are analyzed in-plant: If a carcass cannot be sampled and the sample analyzed by the day after it is collected, the carcass should be held under refrigeration until this is possible. Rinsate from a collected sample should not be held for an extended period of time. It should be either analyzed in-plant the same day as it is collected or by the following day or immediately shipped for overnight delivery to the laboratory that will conduct the analysis. Rinsate, sponge, or product samples should be held at refrigerated temperature, not frozen, and shipped cold to the laboratory in an insulated shipping container with frozen gel packs. FSIS recommends that multiple samples collected on the same day be analyzed individually and not composited into one sample. However, an establishment may consider compositing samples collected from the same Key Question Question: How soon after the samples are collected should they be analyzed to ensure the accuracy of the test results? Answer: To obtain the most accurate results, samples should be analyzed as soon after collection as possible. If samples must be transported to an off-site laboratory, they should be refrigerated and then shipped refrigerated, on the same day they were collected, via an overnight delivery or courier service to the laboratory. A sample should arrive at the laboratory and be analyzed no later than the day after it is collected. 14", "day and at the same point in the process as an option if a quantitative test is used. To help establishments meet regulatory requirements, FSIS is clarifying that establishments may composite samples. Additional information may be required to support compositing of pre-chill samples. If an establishment composites samples, it will need to demonstrate that it has collected sufficient data at various points throughout the pre-chill process over time in order to understand process variations that may be present at the various points in pre-chill where contamination may be redistributed. If the establishment has information to support that minimal variation exists within its pre-chill process then an establishment may elect to composite its pre-chill samples over a production day. However, the compositing of pre-chill and post-chill samples together would not be considered an acceptable practice. If an establishment uses a microbiological test that enumerates an organism, each of the individually composited samples would contribute to the final result. Therefore if the results are normalized (e.g., CFU/g) then these values can be applied to each of the individual samples with the understanding that these results are the average value among all of the composited samples. Microbiological Testing Method The establishment should ensure that microbiological testing meets its food safety needs. An establishment needs to determine whether sample analysis will be performed by an outside laboratory or in its own microbiological testing laboratory onsite (if available). Because of the costs and the logistics involved with maintaining an onsite microbiological testing laboratory, establishments may choose to have samples analyzed by an outside laboratory. FSIS has available the compliance guideline, Establishment Guidance for the Selection of a Commercial or Private Microbiological Testing Laboratory. This guidance document should be particularly useful to very small establishments when they are selecting a commercial or private laboratory to analyze establishment microbiological samples. Establishments should clearly communicate their needs to the testing laboratory and direct them to any necessary testing protocols or other guidance, including this document, on the FSIS Web site. Establishments that select a laboratory that does not apply appropriate testing methods or effective Quality Control\Quality Assurance

(QC\QA) practices may not receive reliable or useful testing results. FSIS has also made available a list of Foodborne Pathogen Test Kits Validated by Independent Organizations for the detection of relevant foodborne pathogens (i.e., *Salmonella*, *Campylobacter*, *E. coli* O157:H7, and *Listeria* spp. including *L. 15*,"*monocytogenes*). These lists are intended to be informational and are not an endorsement or approval of any particular method, regardless of its inclusion in the list. To prevent cross contamination, FSIS recommends that a microbiological testing laboratory be segregated from manufacturing areas and that access to the laboratory space be limited. If the establishment will be performing testing for pathogens onsite, then they should have the following additional safeguards in place to ensure food safety and security: \u2022 Follow requirements for Biosafety Level II laboratory operation as outlined in Biosafety in Microbiological and Biomedical Laboratories (BMBL) available at:

<http://www.cdc.gov/biosafety/publications/bmbl5/BMBL.pdf>; \u2022 Restrict access to the laboratory to trained staff; and \u2022 Ensure the laboratory is operating under the supervision of a qualified microbiologist or equivalent. NOTE: Establishments can (and often do) analyze samples for non-pathogenic organisms such as generic *E. coli* and aerobic plate counts (APC) on-site. The test method used should be validated for the target organisms and for the sample matrix being analyzed to ensure accuracy of the results. It should also be a method validated by a recognized independent body, such as the Association of Official Analytical Chemists (AOAC). Recordkeeping Upon implementation of the sampling program, the establishment must maintain records sufficient to document the implementation and monitoring of sample collection. Records should include the testing procedures, including support for the adequacy of the testing frequency, and the test results and information such as the: \u2022 Time, date, and location of the sample collection. \u2022 Sample collector\u2019s name. \u2022 Name or description of the product or sample source. \u2022 Lot information and producer. All entries should be dated and initialed by the sample collector immediately upon completion of the entry. If an outside laboratory is used for testing, then these records should also include information such as date the sample was shipped to the laboratory for analysis. The outside laboratory should document the: \u2022 Date received; 16"," \u2022 Condition of the sample upon receipt, including sample temperature, if applicable; \u2022 Date the analysis was started and completed; and the \u2022 Analytical result. Test results should also be recorded and linked to the sample collection records by a sample number, form number, or some other unique identifier. These records should be maintained in a way that ensures the integrity of the data. These records can be maintained in an electronic format, provided there are measures in place to ensure the security of the information. These records should be readily accessible for review by the establishment and FSIS inspection program personnel upon request. Charting and Interpreting Test Results Specific techniques of statistical process control include the use of a control chart, which plots data over time but also displays an upper control limit for specific measurements and a centerline, above and below which there is an equal number of sample results (the centerline is in effect an average). A sample result above the upper control limit would indicate the likely presence of a special cause of variation that should be addressed. Results within control limits indicate simply that the process is in control. Control charts are used to (1) analyze and understand variables that affect the process, (2) determine process capabilities, and (3) monitor effects of the variables on the difference between target and actual performance. In most situations more than one type of

control chart would be applicable. Detailed information on the use of control charts can be found in texts on statistical process control, under the topic \u201ccontrol charts\u201d. The following control charts are hypothetical examples of using quantitative microbiological test results, collected over time, to verify the effectiveness of a food safety system (Buchanan).

17","0.0 0.2 0.4 0.6 0.8 1.0 1.2 1.4 1.6 1.8 0 5 10 15 20 25 Log (cfu\/ml) Sample Number Chart 1

- System under control 0.0 0.2 0.4 0.6 0.8 1.0 1.2 1.4 1.6 1.8 0 5 10 15 20 25 Log (cfu\/ml)

Sample Number Chart 2 - Lack of control due to excess variability 0.0 0.2 0.4 0.6 0.8 1.0 1.2 1.4

1.6 1.8 0 5 10 15 20 25 Log (cfu\/ml) Sample Number Chart 3 - Loss of control due to gradual

process failure Chart 1 depicts a pattern of test results that would be seen in a well-controlled system. In a well-controlled system, the majority of test results will be clustered around a central value. It is important to note that even in a well-controlled system; there is some frequency of isolated results above the acceptable level. Chart 2 depicts a loss of process

control due to excess variability. This is reflected in both an increased number of results above the maximum acceptable level and an increase in the scatter of points below the maximum acceptable level. This chart suggests either a loss of control at a critical control point or the existence of another critical control point that had not been identified and controlled. Chart 3 -

depicts a situation where a component of the process is losing its effectiveness over time. This loss of control is apparent by the upward trend in the data points toward the maximum acceptable level. Maximum acceptable level Maximum acceptable level Maximum acceptable

level 18","The test results should be charted and evaluated in a \u201cmoving window\u201d format. For establishments other than very small and VLV establishments operating under the Traditional Inspection System, the test results for both pre-chill and post-chill samples should be plotted and evaluated in a series over time. The results should be evaluated to determine the effectiveness of process control measures in reducing microbiological levels between these two points. The test result chart should be updated within the next business day following the reporting of test results by the testing laboratory. Every time a new test result is recorded, the oldest test in the series is dropped from the moving window. For example, an establishment may choose to evaluate their test results in a moving window of 13 tests. The establishment would use this series of 13 tests to evaluate their process control over the period of time represented by the series of 13 tests. The 0.0 0.2 0.4 0.6 0.8 1.0 1.2 1.4 1.6 1.8 0 5 10 15 20 25 Log (cfu\/ml) Sample Number Chart 4 - Loss of control due to abrupt process failure 0.0 0.2 0.4

0.6 0.8 1.0 1.2 1.4 1.6 1.8 0 5 10 15 20 25 Log (cfu\/ml) Sample Number Chart 5 -Loss of control due to reoccurring transitory process failure Chart 4 depicts a catastrophic loss of process

control. This pattern of test results would be encountered in a situation such as an abrupt failure of a key piece of equipment, such as an antimicrobial wash cabinet. Chart 5 depicts conditions where there is the existence of an intermittent but reoccurring problem within the process. Note the distinct periodicity of the test results over time. An example of a situation where this pattern may be observed is the dripping of condensation onto product as it travels down a conveyor belt Maximum acceptable level Maximum acceptable level 19","control chart would be updated with each new test result reported, adding the new test result and removing the oldest test result on the chart. Microbiological testing provides a measure of the extent of control at the step being evaluated and all preceding steps. By performing microbiological analyses at several points within a process, it is relatively easy to identify the segment of the process where control has been lost. In addition, while it is not required, end-product testing

can provide an integrated measure of the performance of the entire process. Actions in Response to Test Results As part of its process control procedures, an establishment should define the actions it will take if the test results obtained through its sampling are above the limits it has set. The establishment should delineate what its actions will be, who will take each action, how the outcome of these actions will be documented, and how it will be verified. FSIS has made available the FSIS Compliance Guidelines for the Control of Salmonella and Campylobacter in Raw Poultry. The guidelines summarize known control points for Salmonella and Campylobacter in the pre- and post-harvest production process. Establishments should use this compliance guide to improve management practices, to ensure effective sanitary dressing procedures and to assist in investigating when there is a loss of process control. When an establishment makes changes at the appropriate locations, process control should improve. As a result, establishments should produce raw poultry products that have less contamination with pathogens, including Salmonella and Campylobacter. Generally, those interventions to reduce or prevent Salmonella will likewise reduce or prevent Campylobacter. If the establishment determines that the trends in its test results indicate a loss of process control, the establishment should take action to investigate the cause. An establishment should consider how the different parts of its food safety system work together and how they affect the entire food safety system. To do this, establishments should evaluate its process control procedures and sanitary dressing practices to determine whether a root cause can be identified and take steps to correct the problem. This determination should include a review of its process monitoring records as well as evaluation of the process during normal operations. The establishment should consider any implementation problems or changes in its practices, such as sanitary dressing procedures, including but not limited to: \u2022 Procedures for routine cleaning and sanitizing of equipment, including hand tools that are used to remove contamination or to make cuts into the carcass; 20", "\u2022 The design, configuration, and calibration of equipment to ensure proper function within operational parameters to prevent the contact between carcasses and parts and prevent contamination of carcasses during operation; \u2022 Employee hygiene practices, ensuring that employees frequently wash hands and aprons that come in contact with carcasses; and \u2022 The implementation of antimicrobial or mechanical intervention treatments, such as carcass washes, sprays, dips, drenches, or brushes, in accordance with the limits selected by the establishment, including effective application to ensure coverage of the entire carcass. Following its investigation, the establishment should respond appropriately to its findings through the use of decontamination procedures and antimicrobial intervention treatments as necessary to address any contamination that may have occurred on the carcasses and parts. The establishment should also take steps to initiate any necessary equipment repair or recalibration and employee training when identified. Finished Product Standards (FPS) Waivers On July 13, 2011, FSIS announced the Salmonella Initiative Program (SIP) as a voluntary program to provide incentives to establishments to maintain consistent process control to minimize Salmonella levels and to conduct microbial testing to demonstrate that they are maintaining process control (76 FR 41186). In return, establishments received one or more waivers of certain provisions of the regulations, such as those on use of alternative Finished Product Standards (FPS) procedures (9 CFR 381.76). These waivers were authorized under 9 CFR 381.3(b), which provides that the FSIS Administrator may, in specific classes of cases, waive any provisions of the poultry inspection

regulations for limited periods in order to permit experimentation so that new procedures, equipment, and processing techniques may be tested to facilitate definite improvements, provided that such waivers are not in conflict with the purposes or provisions of the Poultry Products Inspection Act (PPIA). FSIS has granted waivers to establishments with respect to testing and other provisions in the FPS regulations, so that establishments could collect data and assess whether this other data would facilitate definite improvements. 21", "The final rule to modernize poultry slaughter inspection (79 FR 49566) amended the poultry regulations to establish an additional inspection system, called the New Poultry Inspection System (NPIS), for young chicken and turkey slaughter establishments. Under the final rule, NPIS does not replace the Streamlined Inspection System (SIS), New Line Speed Inspection System (NELS), and New Turkey Inspection System (NTIS). For establishments that choose to operate under NPIS, the final rule replaces FPS with a requirement that establishments maintain records to document that poultry products resulting from its slaughter operation meet the definition of ready-to-cook (RTC) poultry (9 CFR 381.1). Thus, all FPS waivers will be terminated by operation of the final rule. The purpose of the waivers was to gather the information on how non-food safety defects should be handled. The Agency\u2019s decision on this matter, to go the ready-to-cook standard in NPIS, was based on the information obtained under these waivers. Therefore, the reason for granting the waiver has been fulfilled. The effect of the termination of the waiver will depend on what an establishment elected to do on February 23, 2015 (the opt-in date). Establishments that are operating under FPS waivers and that would like to continue to use their alternative FPS procedures will need to convert to the NPIS. Establishments that notify FSIS of their intent to operate under NPIS may continue to operate under the waiver from FPS requirements until they start operating under NPIS. If establishments choose to operate under SIS, NELS, or NTIS inspection systems (which require complying with FPS), their FPS waiver ends on February 23, 2015. FSIS will give 30 days written notice of the termination of that waiver. Otherwise, establishments will need to submit a request for a new waiver from FPS requirements under SIS, NELS, or NTIS with information on how the waiver would provide new information that would facilitate definite improvements (9 CFR 381.3(b)). FSIS expects that it will be difficult for establishments to meet requirements necessary to obtain a waiver now that NPIS is available. Sampling Frequency Waivers (9 CFR 381.65(g)(2)(i)) The Agency will consider granting waivers of provisions of the 9 CFR 381.65(g)(2)(i) requirements that specify sampling frequency for establishments, except for VLV establishments, to reduce the frequency of sampling below the minimum frequency of once per 22,000 chickens and once per 3,000 turkeys. VLV establishments will not need to request a waiver since the regulations (9 CFR 381.65(g)(ii)) provide for VLV 22", "establishments to reduce their sampling frequency if they are able to demonstrate process control after 13 consecutive samples are collected. These waivers of sampling frequency will be considered provided that the establishment 1) has collected and analyzed data in compliance with 9 CFR 381.65(g)(2)(i) over a minimum of six months (including before or after the effective date of the regulation) to demonstrate consistent process control over time; 2) provides the alternative procedures for reduced sampling frequency that it intends to follow; and 3) provides evidence that its alternative sampling program, along with other control procedures in its plan for preventing contamination by fecal materials or pathogens, will be at least as effective as the required sampling frequency to demonstrate process control. Such establishments may request a waiver of regulations

under the Salmonella Initiative Program (SIP) (76 FR 41186) as described above. FSIS will not grant waivers to 9 CFR 381.65(g)(2)(i) for a testing frequency that is less than the SIP data testing frequencies [i.e., daily Salmonella testing post-chill (one per line per shift) and weekly matched pair at re-hang and post-chill sampling for Salmonella, Campylobacter, and indicator organism] To obtain additional information, send an email to SIP.Mailbox@FSIS.USDA.gov.

**Submitting Monthly SIP Microbial Data:** Establishments operating under a waiver of regulations granted under SIP are required to continue to collect and analyze samples according to the SIP frequency and location; record and evaluate test results; take and document corrective actions, if any; and submit monthly test results on the data sheet provided by FSIS to the SIPMailbox@FSIS.USDA.gov.

In particular, the guidance covers: \u2022 Actions identified by the Interagency Retail Lm Risk Assessment (see page 3) that can decrease the predicted risk of listeriosis from deli products; \u2022 Information from the U.S. Food and Drug Administration (FDA) Food Code, scientific literature, other guidance documents, and lessons learned from meat and poultry establishments that retailers can use to control Lm; \u2022 Steps retailers can take to help ensure that deli products are maintained under sanitary conditions that do not allow Lm adulteration of the product; and \u2022 A self-assessment tool that retailers can use to determine what practices they are currently using and what new practices to adopt to control Lm.", "Table of Contents Purpose 1 Introduction 1 Regulation of Meat and Poultry Products at Retail The Interagency Retail Lm Risk Assessment Findings 2 3 How to Use this Guidance 6 Product Handling 7 Cleaning and Sanitizing 9 Facility and Equipment Controls 11 Employee Practices 12 Deli Self-Assessment Tool References and Resources 14 15 ii", "Purpose This guidance document provides specific recommendations for actions that retailers can take in the delicatessen (deli) area to control *Listeria monocytogenes* (Lm) contamination of ready-to-eat (RTE) meat and poultry products. These materials highlight recommendations that are based on an evaluation of retail conditions and practices in the Interagency Risk Assessment-Listeria monocytogenes in Retail Delicatessens (Interagency Retail Lm Risk Assessment). In

addition, FSIS has included information from the Food and Drug Administration (FDA) Food Code, scientific literature, other guidance documents, and lessons learned from Food Safety and Inspection Service (FSIS) verification sampling and review of sanitation programs for Lm in meat and poultry processing establishments. This version of the guidance document replaces the previous version of the document which was issued and announced in the Federal Register (79 FR 22082; April 21, 2014). FSIS updated this guidance based on comments received during the public comment period, which closed on June 20, 2014. FSIS made the following changes in response to comments:

- \u2022 Clarified that food processing equipment should be disassembled during cleaning and sanitizing.
- \u2022 Added a recommendation that retailers scrub surfaces during cleaning to prevent biofilm formation.
- \u2022 Clarified that retailers should rotate (change) sanitizers to help prevent Lm from establishing niches in the environment and forming biofilms.

Although comments will no longer be accepted through regulations.gov on this guidance document, FSIS will update this document as necessary, should new information become available.

**Introduction**

Lm is a bacterium that is found in moist environments, soil, and decaying vegetation and can persist along the food continuum. Transfer of the bacteria from the environment (e.g., deli cases, slicers, and utensils), employees, or raw food products is a particular hazard of concern in RTE foods, including meat and poultry products. Listeriosis is a serious infection usually caused by eating food contaminated with Lm. Controlling Lm has long been an objective of the public health community. The Centers for Disease Control and Prevention (CDC) estimates that infection with Lm causes about 1,600 illnesses, 1,500 hospitalizations, and 260 deaths in the United States each year. Listeriosis is rare, but its fatality rate is very high (about 16 percent, compared with 0.5 percent for either *Salmonella* or *E. coli* O157:H7) (Scallan et. al., 2011). It primarily affects older adults, pregnant women, newborns, and adults with weakened immune systems. Lm can survive and grow at cool temperatures (as low as 34\u00b0F/1\u00b0C). Because of its growth and survival characteristics, Lm is usually persistent in the environment and is commonly referred to. The CDC estimates that Lm causes a high level of deaths compared to other foodborne pathogens. Deli products have been shown to be a major contributor to these illnesses. Retailers can help decrease the risk of illness by controlling Lm contamination in the deli. Lm is a harborage organism (i.e., it can form niches and grow to high numbers in the environment; niches provide an ideal place for Lm to establish and multiply). It can cross-contaminate food contact surfaces and foods. Improper sanitation, product handling, and employee practices can lead to the transfer of Lm to RTE meat and poultry products at retail causing them to become adulterated (see Regulation of Meat and Poultry Products at Retail below). RTE meat and poultry products do not require cooking prior to being consumed and are often held at refrigerated temperatures. Once contaminated with Lm, RTE food products may provide an ideal environment for this harmful bacterium to grow. A variety of retail surveys of deli meats and a number of risk assessments of Lm in deli-sliced versus pre-packaged deli meats have analyzed the risk of listeriosis associated with deli prepared meat and poultry products. The FSIS Comparative Risk Assessment for Lm in Ready-to-eat Meat and Poultry Deli Meats (May 2010) estimated that of listeriosis illnesses attributed to deli meat, 83% are associated with deli meat sliced and packaged at retail (Endrikat et al. 2010). Safe food handling practices, thorough cleaning and sanitation procedures, maintenance of the facility and equipment, and good employee practices are key components that may prevent or reduce the likelihood of RTE foods

becoming contaminated in retail delis. Regulation of Meat and Poultry Products at Retail FSIS shares jurisdiction with FDA and with State, local, and tribal authorities for meat and poultry products at retail. FDA makes recommendations regarding retail practices through the FDA Food Code. The Food Code is used by the State and local agencies as a model to establish regulations, ordinances, and actionable policies that can be enforced in their jurisdictions. Operators of retail establishments are required to comply with the conditions of the permit or license under which they operate. The Federal Meat Inspection Act (FMIA) and Poultry Products Inspection Act (PPIA) apply to meat and poultry products produced in federally inspected establishments and other entities producing or handling meat and poultry, including at retail. Although retail firms are generally exempt from FSIS inspection, retailers are required to maintain sanitary conditions and otherwise not produce adulterated or misbranded product (21 U.S.C. 623(d) and 464(e); 9 CFR 303.1(f) and 381.10(d)(4)). The types of operations that are traditionally and usually conducted at retail stores can be found in 9 CFR 303.1(d)(1) and 9 CFR 381.10(d)(1). FSIS provides instructions to its personnel for surveillance activities at retail in FSIS Directive 8010.1. The purpose of in-commerce surveillance is to ensure that FSIS-regulated meat and poultry products distributed in commerce are: \u2022 Safe, wholesome, and not adulterated; \u2022 Correctly marked, labeled, and packaged; \u2022 Secure from intentional acts of contamination, and \u2022 Legally imported and properly exported. When performing in-commerce surveillance, FSIS verifies that: 1. Meat and poultry are wholesome and not adulterated; 2. Sanitary conditions are such that meat and poultry will not become contaminated with filth or rendered injurious to health; 3. Hazard controls are adequate to prevent meat and poultry from becoming adulterated; 4. Meat or poultry not intended for use as human food are properly denatured or otherwise made inedible as prescribed by Federal regulations; and 5. All records are kept and maintained in a manner that fully and correctly discloses all transactions involved in the business activity that is subject to the provisions of the FMIA and PPIA. This guidance does not replace the FDA Food Code, State, tribal or local, or FSIS regulations. This document can be used along with the 2013 FDA Food Code to help retailers ensure that meat and poultry products are not prepared or sliced under insanitary conditions in the retail deli area, which can lead to Lm contamination and outgrowth of the organism on the product. The Interagency Retail Lm Risk Assessment Findings The Interagency Retail Lm Risk Assessment was jointly developed by FSIS and FDA, and in consultation with the CDC, to help guide food safety efforts to minimize the public health burden of listeriosis in the U.S. The risk assessment was conducted to better understand how retail practices (e.g., temperature control, sanitation, worker behavior) influence the public health risk of listeriosis associated with eating deli products (e.g., meats, cheeses, and salads) sliced or prepared in retail. It also examines how effective various interventions are in limiting the survival, growth, or crosscontamination of Lm. The risk assessment is based on observations of: \u2022 Deli employees' work routines; \u2022 Concentrations of Lm on incoming products and in the deli environment; \u2022 Studies on the ability of Lm to spread in retail delis, such as from a slicer to food; and \u2022 An existing dose-response model. The study was designed to apply to a range of deli establishments, from small independent operations to the deli departments in large supermarkets. The risk assessment also reinforces the importance of FDA's Food Code recommendations to operators of retail delis. State, local, and tribal jurisdictions can do their part to reduce listeriosis by enforcing all relevant provisions of the 2013 FDA Food Code as part

of their own food safety requirements. The risk assessment found that certain practices are needed to effectively prevent crosscontamination and limit Lm growth in RTE foods handled or prepared in retail delicatessens, including: No single action or practice will control Lm contamination of retail foods. Instead there are many steps that retail deli operators and their suppliers can take to help reduce the risk of listeriosis. 3", "\u2022 Proper storage, \u2022 Adequate sanitation, and \u2022 Effective employee practices. NOTE: This guidance document includes key findings from the Interagency Retail Lm Risk Assessment and provides an overall summary of the data for typical retail deli settings. More detailed information regarding the findings is in the Retail Lm Risk Assessment Report. 4", "Key Findings The following are key findings of the Interagency Retail Lm Risk Assessment for typical retail deli settings. \u2022 Storage Temperature. If all refrigerated RTE foods are stored at 41\u00b0F (5\u00b0C) or below, as the 2013 FDA Food Code (3-501.16(A)(2)) recommends, approximately 9% of predicted listeriosis cases caused by contaminated deli products prepared or sliced in the retail deli could be prevented. \u2022 Growth Inhibitors. If all deli products that support Lm growth were reformulated to include growth inhibitors, approximately 96% of predicted listeriosis illnesses caused by RTE products prepared or sliced in the retail deli could be prevented. While this finding is significant, the actual benefit may be smaller in part because the concentration of the growth inhibitor used may not be sufficient to be effective throughout the shelf life of a food or may not be used in high enough concentrations because the inhibitors can adversely affect the flavor of the product. \u2022 Control Cross-Contamination. The predicted risk of listeriosis dramatically increases in retail delis as a result of cross-contamination. In particular, slicers are key sources of crosscontamination in retail delis. Eliminating all points of cross-contamination in the deli (including slicers) would decrease the predicted risk of illness from the consumption of RTE products prepared or sliced in the retail deli by approximately 34%. Cross-contamination is particularly difficult to control completely; however, the risk assessment shows that proper product handling, cleaning, sanitizing, and glove use help prevent cross-contamination. \u2022 Control Contamination at its Source. Increased levels of Lm from incoming products and the environment (including potential niches), directly increases the predicted risk of illness. Therefore, elimination of environmental niches in the deli area will reduce the predicted risk of listeriosis from the consumption of RTE products prepared or sliced in the retail deli. Additionally, if levels of Lm on RTE foods (including foods that do not support the growth of Lm) that the retail deli receives from processing establishments were reduced by half, approximately 22% of the predicted listeriosis illnesses caused by contaminated deli products could be prevented. This finding suggests that continued efforts to prevent low levels of Lm contamination during processing, even on products that do not support growth of the pathogen, reduces the predicted risk from these products and other RTE foods that can be subsequently cross-contaminated in the retail delis. \u2022 Continue Sanitation. Sanitation practices that eliminate Lm from deli food-contact surfaces reduce the predicted risk of illness. Cleaning and sanitizing food-contact surfaces reduces the predicted Lm levels in the deli area. Employees not wearing gloves while serving customers increases the predicted risk of listeriosis from the consumption of RTE products prepared or sliced in the retail deli by approximately 5%. 5", "How to Use this Guidance This guidance provides practical recommendations that retailers can use to control Lm contamination and outgrowth in the deli area based on the findings of the Interagency Retail Lm Risk Assessment, available scientific knowledge, the 2013 FDA Food

Code, as well as lessons learned from controlling Lm in meat and poultry processing establishments. Retailers can use this best-practices guidance to help ensure that RTE meat and poultry products in the deli area are handled under sanitary conditions and are not adulterated as defined in the FMIA and PPIA. While these practices are designed to control Lm specifically, they also may help control other food borne pathogens that may be introduced into the retail deli environment and other facilities where consumers take possession of food. The best practices are divided into four sections: (1) product and product handling, (2) cleaning and sanitizing, (3) facility and equipment controls, and (4) employee practices. Practices identified by the risk assessment that can significantly decrease the predicted risk of foodborne illness are highlighted in each section. The other practices that are based on scientific knowledge or lessons learned also will help retailers increase Listeria control in the deli area. For example, although floors and drains were not considered as a source of crosscontamination according to the Interagency Retail Lm Risk Assessment, FSIS data has shown that floors, drains, and items like floor mats tend to be harborage points in FSIS establishments. Providing this information can assist retailers in controlling Lm in the deli area. A selfassessment tool, starting on page 14 of this guidance, is provided for deli operators to help them identify the best practices they are using and to assess whether they need to adopt others. By following the best practices in the guidance and the 2013 FDA Food Code, retailers can help ensure that RTE products are not adulterated with Lm, and that the potential for listeriosis is decreased. NOTE: Retailers should be aware that the recommendations in this guidance, especially those based on the 2013 Food Code may be requirements in State, local, or tribal regulations. Questions on this guidance may be submitted through AskFSIS. 6", "Product Handling The Interagency Retail Lm Risk Assessment found that using practices that prevent bacterial growth in the product substantially reduced the predicted risk of listeriosis. In addition, while the risk assessment showed that the risk from incoming Lm-contaminated products that do not support growth is low, it also showed that these products can cross-contaminate RTE products that support growth, and when they do, the risk increases substantially. The formulation of RTE products with antimicrobial agents prevents growth of Lm in RTE foods both at retail and during consumer home storage, leading to an overall reduction in the predicted risk of listeriosis. The 2013 FDA Food Code (3501.16(A)(2)) recommends keeping RTE products at or below 41\u00b0F (5\u00b0C), which slows the growth of Lm in the deli and decreases the predicted risk for listeriosis. Other scientific studies also have shown that preventing product contamination reduces the risk of foodborne illness. Therefore, it is important for retailers to adopt practices that protect RTE product from contamination with Lm and to use strategies to prevent or limit the growth of Lm in deli products. Below are a few such strategies. \u2022 Use products formulated with antimicrobial agents (e.g., acetic acid, sodium diacetate, lactic acid, citric acid) when possible, to eliminate or prevent the growth of Lm in RTE products. In some cases, the addition of antimicrobial agents may not be possible because of the adverse effect on the flavor of the products. Retailers can read the ingredients statements on the labels to see whether the products in the deli have antimicrobial agents and can contact their suppliers to determine whether products formulated with antimicrobial agents are available. NOTE: As stated previously, the Interagency Retail Lm Risk Assessment estimated that if antimicrobial agents are used in all products in the deli, the predicted risk of listeriosis from the consumption of RTE products sliced or prepared in retail departments could be decreased by approximately 96%.

Things to Consider at Retail \uf0fc Are the deli products being sold formulated with antimicrobial agents? \uf0fc Is RTE product properly identified and labeled? \uf0fc Are RTE products identified with the date the package is opened? \uf0fc Is RTE product discarded if it is past the recommended discard date? \uf0fc Is there a process to routinely remove RTE products that are not suitable for sale from the retail case? \uf0fc Are RTE meat and poultry products promptly refrigerated after use? \uf0fc Are RTE products prepared and stored adjacent to raw product? \uf0fc Is the retail deli case maintained at 41\u00b0F (5\u00b0C) or below to prevent pathogen growth? \uf0fc Is RTE product covered, wrapped, or otherwise protected after opening? \uf0fc Are RTE products placed on the same contact surfaces as other RTE product, e.g., cheese, vegetables, seafood? 7", "\u2022 Use products that have been treated to reduce pathogens (e.g., through high pressure processing (HPP)). This information can be determined from certificates of analysis (COA), letters of guarantee (LOG), or other information from suppliers. Separate products that support growth from products that do not support growth (when possible) to help prevent cross contamination. NOTE: As stated previously, the Interagency Retail Lm Risk Assessment found that if current levels of Lm in RTE foods (e.g., meats, cheeses, and salads) received by the retail deli were reduced by half, the predicted risk of listeriosis from the consumption of RTE products sliced or prepared in retail deli departments could be decreased by approximately 22%. \u2022 Monitor the shelf life of an RTE product that is opened, prepared, and held in a retail setting for more than 24 hours. To monitor shelf life of the opened product, retailers should date-mark the product (e.g., clearly mark it with the date of opening and the discard date) as recommended by the 2013 FDA Food Code (3-501.17). Products also should be properly identified and labeled. RTE products that are past their shelf life should be discarded. \u2022 Do not pre-slice products in the morning, after cleaning. Retailers should slice the product at the time it is requested by consumers. NOTE: The Interagency Retail Lm Risk Assessment found that pre-slicing the product increases the predicted risk of listeriosis from the consumption of RTE products sliced or prepared in retail deli departments by approximately 6%. \u2022 Remove products that are filthy, putrid, decomposed, slimy, rancid, or in off-condition, which are considered adulterated, from the deli area as soon as possible. Thoroughly clean and sanitize areas that were contacted by the affected product to prevent any cross-contamination. \u2022 Promptly return RTE products to refrigerated units, after slicing, to prevent pathogen growth. Maintain refrigeration units at or below 41\u00b0F (5\u00b0C) to slow the growth of Lm, as recommended by the 2013 FDA Food Code (3-501.16(A)(2)). RTE products should be covered, wrapped, or otherwise protected to prevent cross-contamination when not in use. NOTE: The Interagency Retail Lm Risk Assessment found that storing the products at or below 41\u00b0F (5\u00b0C) decreases the predicted risk of listeriosis from the consumption of RTE products sliced or prepared in retail deli departments by approximately 9%. \u2022 Store and handle RTE products in separate areas from raw products. RTE products that are prepared, held, or stored near raw products can become contaminated (e.g., because of aerosolization or dripping). The 2013 FDA Food Code (3-302.11(A)(1)) recommends that retailers separate RTE foods from raw foods. If storage space is limited, wrap the products and store RTE products above raw products. When wrapping, unwrapping, and slicing products, take care to prevent cross-contamination from the outer wrapper, other products, and unclean surfaces and utensils. Raw 8", "products (e.g., chicken used for frying or rotisserie) prepared in the same area as RTE products can increase

the potential for cross-contamination. \u2022 Clean and sanitize surfaces between RTE items when using the same equipment to cut, slice, or otherwise reduce the size of large RTE products (e.g., ham, seafood, and vegetables). \u2022 Ensure that grinders, dicers, or other equipment are maintained in sanitary condition when preparing deli salads. Cleaning and Sanitizing The Interagency Retail Lm Risk Assessment found that following the sanitation practices in the 2013 FDA Food Code aid in controlling Lm on deli area food contact surfaces and reduces the predicted risk of listeriosis. The 2013 FDA Food Code (4-602.11(C)) recommends cleaning equipment and utensils at least every 4 hours. Below are some key issues to consider when cleaning and sanitizing. \u2022 Develop written sanitation procedures that describe how utensils and equipment (e.g., slicers) will be cleaned and sanitized prior to use. Ensure employees are familiar with and follow these procedures to reduce the risk of contaminating RTE products with Lm. Insanitary conditions (e.g., flies, rodent droppings, mold, or dirty surfaces) should not be present in retail areas. Retailers should document the actions they perform to ensure that sanitation procedures are performed on a regular basis. NOTE: The Interagency Retail Lm Risk Assessment found that the predicted risk of listeriosis from the consumption of RTE products sliced or prepared in retail deli departments increases by approximately 41% if wiping, washing, and sanitizing activities are not performed. \u2022 Clean and sanitize utensils and equipment used to handle, prepare, and store RTE products frequently (e.g., at least every 4 hours as recommended by the 2013 FDA Food Code (4-602.11 (C)) to maintain sanitary conditions throughout the day. Things to Consider at Retail \uf0fc Are sanitation procedures documented? \uf0fc Are RTE product contact surfaces cleaned and sanitized prior to use? \uf0fc Are routine cleaning and sanitation procedures performed in areas where RTE products are handled, stored, and sold? \uf0fc Is RTE equipment disassembled before cleaning and sanitizing? \uf0fc Are surfaces scrubbed during cleaning to prevent biofilm formation? \uf0fc Are sanitizers used at the recommended concentrations? \uf0fc Are sanitizers rotated on a periodic basis? \uf0fc Are cleaning cloths rinsed or soaked in sanitizer between uses? \uf0fc Are only low-pressure water sources (hoses) used during cleaning to prevent splashing? 9", "Clean and sanitize items that employees routinely handle, such as on/off switches, slicer handles, display cases, cooler handles, and similar surfaces. NOTE: As stated previously, the Interagency Retail Lm Risk Assessment found that slicers are sources of Lm cross-contamination to RTE foods. Control of Lm crosscontamination at all points (including slicers) during retail preparation and handling of RTE foods will reduce the predicted risk of listeriosis from the consumption of RTE products sliced or prepared in retail deli departments by approximately 34%. \u2022 Disassemble RTE food-processing equipment when cleaning and sanitizing equipment as recommended by the Food Code to ensure that hard to reach areas where Lm can hide are addressed. For more information, see the FDA poster: Keep Commercial Deli Slicers Safe. \u2022 Scrub surfaces during cleaning to prevent biofilms from occurring. Biofilms are thin layers of microorganisms that adhere to product contact surfaces. Lm and other bacteria can adapt to the environment over time and form biofilms. Biofilms are difficult to remove, and they may protect Lm from the effects of sanitizers. \u2022 Follow the manufacturer\u2019s recommendations for sanitizer strength and application to ensure it is effective. Many sanitizers, when used as recommended, are effective against Lm, including those containing quaternary ammonia compounds, chlorine solutions, and organic acids. Generally, increasing the sanitizer strength above the recommended levels will not increase the

efficacy of the sanitizer and may result in harmful levels of the sanitizer in foods. \u2022 Rotate (change) sanitizers as needed to provide more effective bacterial control. Alternating sanitizers (e.g., quaternary ammonia and bleach) may help prevent Lm from establishing niches in the environment and forming biofilms. For example, retailers can use quaternary ammonia on the week days and bleach on the weekends when rotating sanitizers. \u2022 Develop a procedure to sanitize cleaning aids or have single-use items that are discarded after use. Cleaning cloths, brushes, sponges, mops, and similar cleaning aids can become contaminated with bacteria and then can spread the bacteria to every surface they contact. Therefore, they should be cleaned of visible material and soaked in clean sanitizer between uses. Retailers should monitor sanitizer strength and change the sanitizer as needed so that food particles do not overwhelm the effectiveness of the sanitizer. \u2022 Use low water pressure when cleaning in the deli areas. Splashing and overspray from high-pressure hoses can aerosolize microorganisms and distribute them into the air and onto nearby surfaces. \u2022 Use separate sinks for hand washing and cleaning product or equipment (as recommended by the 2013 Food Code (2-301.15 and 4-501.16)). Hand washing can cause the sink to be contaminated with Lm and other pathogens, which can be spread to any other items cleaned in the sink. 10", "\u2022 Eliminate or remove unnecessary items (e.g., supplies and equipment) from the deli area. Organize supplies and equipment to facilitate thorough cleaning. Facility and Equipment Controls As stated on page 4, the Interagency Retail Lm Risk Assessment found that increasing the level of Lm and the potential of cross-contamination increases the predicted risk of listeriosis. The 2013 FDA Food Code (6-101.11(A)(1)) recommends that floors, walls, and ceilings be smooth, durable, and easily cleanable. Facilities, equipment, and utensils should not contribute to product adulteration or contamination. Here are some areas to check and some insanitary issues to avoid. \u2022 Do not allow conditions in the retail facility that could cause the product to become adulterated. These conditions could include condensation dripping on exposed product, construction dust on product or food contact surfaces, or broken equipment which could harbor Lm. \u2022 Ensure that walls, floors, drains, and overhead structures in the RTE deli and cooler areas are smooth, durable, easily cleanable, and in good repair. Rubber floor mats and other items used on the floor may be harborage sites for Lm. Clean them as often as necessary to ensure that sanitary conditions are maintained. \u2022 Do not perform construction (e.g., replacing floors, walls, or ceilings) when exposed RTE product is present in the deli. Lm can be harbored behind the walls and carried by dust. Therefore, the product and equipment should be protected during construction, and the deli area should be cleaned and sanitized after construction and before use. \u2022 Maintain tables, slicers, and other food contact surfaces so that they are easily cleanable. Rough surfaces created by welds, cracks, and other defects can be difficult to clean and can create areas where bacteria can hide. Replace worn, missing, or degraded seals or gaskets because they may become contaminated with Lm. \u2022 Clean overhead structures as often as necessary to keep them free of condensation and ensure that sanitary conditions are maintained. Overhead items (e.g., cracked light fixtures) can be Lm harborage points. Condensation on overhead structures can lead to contamination of food or food preparation surfaces. \u2022 Keep water from pooling on the floor or other surfaces within the deli area. Doing so will reduce the likelihood that splashes could contaminate food products or food contact surfaces. Standing water can serve as a vehicle for Lm and other pathogens. Things to Consider at Retail \uf0fc Is the facility structure in good

repair to prevent contamination or adulteration of products in the deli area? \uf0fc Is the equipment nonporous and free of cracks, pits, and rough welds? \uf0fc Is the overhead structure in the deli area free of condensation? \uf0fc Is the deli area free of standing water on floors or product contact surfaces? 11", "Employee Practices As mentioned previously, the Interagency Retail Lm Risk Assessment found that wearing gloves while serving customers reduces the predicted risk of listeriosis. The 2013 FDA Food Code also recommends that employees wear gloves or use other suitable utensils to handle RTE foods and includes recommendations for training, hand washing, employee health and hygiene, and limiting public access in deli areas to prevent product contamination (references below). Good employee hygiene practices are critical to prevent cross-contamination and the spread of Lm and other pathogens. Lm can be present on, and spread by, equipment, materials, foods, and people. Here are a few employee practices retailers can use to minimize cross-contamination. \u2022 Ensure that employees wear gloves or use suitable utensils when handling RTE products, as recommended by the 2013 FDA Food Code (3-301.11(B)). Provide disposable gloves so that employees wear and change gloves, as needed, to prevent the contamination of food. NOTE: The Interagency Retail Lm Risk Assessment found that employees not wearing gloves increases the predicted risk of listeriosis from the consumption of RTE products sliced or prepared in the retail deli department by approximately 5%. \u2022 Train employees in sanitation practices and safe food handling procedures. Ensure that the manager has knowledge of food safety practices and procedures, as recommended by the 2013 FDA Food Code (2-102.11), and that employees have been properly trained in hygienic practices. \u2022 Provide adequate facilities, including soap and running water, for employees to wash their hands. As recommended by the 2013 FDA Food Code (2-301.14), employees should wash hands prior to gloving, when switching between handling raw and RTE foods, after engaging in other activities that may contaminate the hands (e.g., handling money or potentially dirty or contaminated surfaces), or using the restroom. \u2022 Implement a policy to ensure that ill employees do not work with open food items, including RTE foods. For example, written procedures should include removing workers from the deli when they are ill with respiratory or diarrheal diseases, as recommended by the 2013 FDA Food Code (2-201.11). Things to Consider at Retail \uf0fc Are there procedures to prevent ill employees from working in the food preparation area? \uf0fc Do employees wash hands prior to handling exposed RTE product? \uf0fc Do employees wear disposable gloves when handling exposed RTE product? \uf0fc If employees wear disposable gloves, do they change them, as necessary, to prevent crosscontamination (e.g., after handling raw product or money) when handling RTE product? \uf0fc Is foot traffic limited in RTE food product handling areas? 12", "\u2022 Limit employee traffic in the deli area and develop traffic-flow plans for product, employees, and other items to prevent contamination by consumers and employees. The plans should minimize exposure of open RTE foods to raw foods, exterior packaging, and other possibly contaminated materials, such as boxes, trash, and chemicals. Designing facilities and controlling traffic in the deli area to restrict movement of people and material reduces the chance of cross-contamination. Non-deli workers should not handle exposed RTE products. \u2022 Develop practices to prevent outer clothing from spreading contamination. Ensure that employees change their aprons or outer clothing, such as frocks or smocks, when the clothing is soiled with food or dirt particles that could transfer to food or food contact surfaces. Employees should not hold exposed RTE food products against their aprons or other clothing. Employees

should not wear this outer clothing into restrooms, in break areas, or outside the deli area.

13", "Deli Self-Assessment Tool Retailers should use this tool to determine whether they have adopted the appropriate procedures to control L<sub>m</sub>, or whether they should adopt new procedures. The preferred answer (based on the information in the guidance) is indicated with an asterisk. Having a \u201cno\u201d answer does not necessarily indicate lack of control. If retailers find that they are not meeting the recommendations in this guidance, they should consider changing practices to better control L<sub>m</sub> in the deli area.

Product\ Product Handling:

RTE Deli Area YES NO N\A

1. Is any visibly adulterated product present in the area (e.g., filthy, putrid, decomposed, slimy, rancid, off-condition)? \u25a1 \u25a1\* \u25a1
2. Are RTE meat or poultry products refrigerated promptly after use? \u25a1\* \u25a1 \u25a1
3. Is RTE product prepared, held, or stored near or adjacent to raw product in the deli case and elsewhere in the deli area? \u25a1 \u25a1\* \u25a1
4. Is the RTE product date-marked when opened? \u25a1\* \u25a1 \u25a1
5. Is there any RTE product in the deli case that is outside of the date-marked period? \u25a1 \u25a1\* \u25a1
6. Are the deli cases and other refrigerated units maintained at or below 41\u00b0F (5\u00b0C)? \u25a1\* \u25a1 \u25a1
7. Is opened RTE product covered, wrapped, or otherwise protected to prevent cross-contamination when not in use in the deli case and elsewhere in the deli area? \u25a1\* \u25a1 \u25a1
8. Is RTE product stored in the deli case properly identified and labeled? \u25a1\* \u25a1 \u25a1
9. Do you use deli products formulated with antimicrobial agents? \u25a1\* \u25a1 \u25a1
10. Are RTE product contact surfaces cleaned and sanitized prior to using the surface for another product to avoid cross-contamination of products? \u25a1\* \u25a1 \u25a1
11. If you prepare deli salads, are there controls in place to ensure that grinders, dicers, or other equipment are maintained in sanitary condition? \u25a1\* \u25a1 \u25a1

Cleaning\Sanitizing:

RTE Deli Area YES NO N\A

  12. Are insanitary conditions (e.g., flies, rodent droppings, mold, or dirty surfaces) present in areas where meat and poultry products are prepared, packed, or held? \u25a1 \u25a1\* \u25a1
  13. Do you use sanitizers at the proper concentration? \u25a1\* \u25a1 \u25a1
  14. Do you clean and sanitize the RTE equipment (including slicers) at least every 4 hours? \u25a1\* \u25a1
  15. Do you disassemble RTE equipment (including slicers) during cleaning and sanitizing? \u25a1\* \u25a1 \u25a1
  16. Do you scrub surfaces during cleaning to prevent biofilms? \u25a1\* \u25a1 \u25a1
  17. Do you soak or rinse cleaning cloths in sanitizer between uses? \u25a1\* \u25a1 \u25a1
  - 14", "18. Are sanitizer types (e.g., quaternary ammonium, chlorine- based, or iodophores) rotated periodically? \u25a1\* \u25a1 \u25a1
  19. Do you clean the RTE area with a high pressure hose (e.g., with enough pressure to cause splashing)? \u25a1 \u25a1\* \u25a1
  20. Are there separate sinks for hand washing and other uses? \u25a1\* \u25a1 \u25a1
  21. Do you have material (e.g., pallets, milk cartons, cardboard boxes, or push carts) in the deli area that makes cleaning difficult? \u25a1 \u25a1\* \u25a1

Facility:

RTE Deli Area YES NO N\A

    22. Are there facility conditions (e.g., condensation dripping on exposed product, construction dust on product, or broken equipment) that could cause the product to become adulterated? \u25a1 \u25a1\* \u25a1
    23. Is there condensation on overhead structures or over the RTE product? \u25a1 \u25a1\* \u25a1
    24. Is there standing water on surfaces, including the floor? \u25a1 \u25a1\* \u25a1
    25. Are product contact surfaces in good condition (e.g., non-porous surfaces, free from cracks, pits, and rough welds)? \u25a1\* \u25a1 \u25a1
    26. Are slicers and mixers in good condition (e.g., free of cracks, broken, missing or unattached parts; seals and gaskets not worn, degraded, or missing)? \u25a1\* \u25a1 \u25a1
    27. Are the walls,

floors, and ceilings sanitary and in good repair? \u25a1\* \u25a1 \u25a1 Employee Practices: RTE Deli Area YES NO N/A 28. Are visibly ill employees working in food preparation areas where product could become contaminated (e.g., by coughing or sneezing)? \u25a1 \u25a1\* \u25a1 29. Do employees work without washing hands prior to handling exposed RTE product? \u25a1 \u25a1\* \u25a1 30. Do employees wear disposable gloves when handling exposed RTE product that will not be cooked? \u25a1\* \u25a1 \u25a1 31. If employees wear gloves, do they change them as necessary to avoid cross-contamination of RTE product? \u25a1\* \u25a1 \u25a1 32. Do employees change outer clothing (e.g., frocks, aprons, or smocks) as often as necessary to avoid contamination of RTE product? \u25a1\* \u25a1 \u25a1 33. Is foot traffic limited to necessary employees in areas where RTE product is handled? \u25a1\* \u25a1 \u25a1

*Listeria monocytogenes* (Lm) Lm is a bacteria found in moist environments, soil, and decaying vegetation. It causes the foodborne illness, listeriosis. Transfer of Lm from the environment, equipment, employees, or raw food is a particular hazard of concern in retail delis. It can cross-contaminate food contact surfaces and foods. Improper sanitation, product handling, and employee practices can lead to the transfer of Lm to RTE meat and poultry products at retail. Lm forms biofilms (thin layers of microorganisms that stick to product contact surfaces) that are difficult to remove from equipment and other surfaces. Listeriosis Serious infection can result from eating food contaminated with Lm. Infection is rare, but could result in a high fatality rate (16% compared to 0.5% for *Salmonella* or *E. coli* O157:H7). It affects everyone, with older adults, pregnant women and fetuses, newborns, children, and adults with weakened immune systems being at higher risk. Flu-like symptoms can begin a few days after consuming contaminated products. However, invasive listeriosis, which can affect the central nervous system and may cause stillbirth or result in death, can begin up to 2 months after eating food contaminated with Lm. There are an estimated 1,600 illnesses, 1,500 hospitalizations, and 260

"]}

deaths in the U.S. each year. Product Handling It is important to adopt practices that protect RTE product from contamination with Lm (see bullets below on ways to prevent or limit the growth of Lm in deli products). \u2022 Use products that contain antimicrobial agents or have received other treatments to eliminate or prevent the growth of Lm in RTE products. \u2022 Monitor and limit the shelf life of an RTE product that is opened, prepared, and held in a retail setting for more than 24 hours. \u2022 Do not pre-slice products - product should be sliced at the time it is requested by consumers. \u2022 Remove products that are filthy, putrid, decomposed, slimy, rancid, or in off-condition from the deli area as soon as possible and thoroughly clean and sanitize areas that were contacted by such product to prevent any cross-contamination. \u2022 Promptly return RTE products to refrigerated units (at or below 41\u00b0F), after slicing, to slow pathogen growth. \u2022 Store and handle RTE products in separate areas from raw products. RTE products that are prepared, held, or stored near raw products can become contaminated (e.g., because of aerosolization or dripping). A number of food safety practices are needed to control Lm contamination of retail foods. Cleaning and Sanitizing \u2022 Develop written sanitation procedures that describe how utensils and equipment (e.g., slicers) will be cleaned and sanitized prior to use. \u2022 Clean and sanitize utensils and equipment used to handle, prepare, and store RTE products frequently (e.g., at least every 4 hours). \u2022 Disassemble RTE food-processing equipment when cleaning and sanitizing to ensure that hard to reach areas where Lm can hide are addressed. \u2022 Scrub surfaces during cleaning to prevent biofilms from occurring. \u2022 Follow the manufacturer's recommendations for sanitizer strength and application, including exposure time, to ensure it is effective. \u2022 Consider rotating sanitizers to provide more effective bacterial control. \u2022 Develop a procedure to sanitize cleaning aids (e.g., cloths and scrub brushes) or have singleuse items that are discarded after use. \u2022 Use low water pressure when cleaning in the deli areas to minimize splashing and overspray. \u2022 Use separate sinks for hand washing and cleaning product or equipment. \u2022 Eliminate or remove unnecessary items (e.g., supplies and equipment) from the deli area.", "Employee Practices \u2022 Train employees in sanitation practices and safe food handling procedures. \u2022 Ensure that employees wear gloves and change them as needed to prevent crosscontamination of RTE products. \u2022 Provide adequate facilities, including soap and running water, and post instructions for employees to wash their hands. \u2022 Implement a policy to ensure that ill employees do not work with open food items, including RTE foods. \u2022 Limit employee traffic in the deli area and develop traffic-flow plans for product, employees, and other items to prevent contamination by consumers and employees. \u2022 Develop practices to prevent outer clothing from spreading contamination, such as wearing disposable aprons. For more information and a checklist of practices for your deli, go to FSIS Best Practices Guidance for Controlling Listeria monocytogenes (Lm) in Retail Delicatessens at [http://www.fsis.usda.gov/wps/wcm/connect/29d512\\_58-0651-469b-99b8-e986baee8a54/Controlling-LMDelicatessens.pdf?MOD=AJPERES](http://www.fsis.usda.gov/wps/wcm/connect/29d512_58-0651-469b-99b8-e986baee8a54/Controlling-LMDelicatessens.pdf?MOD=AJPERES) See the FDA Food Code, 2013, at: <http://www.fda.gov/Food/GuidanceRegulation/RetailFoodProtection/FoodCode/ucm374275.htm> Additional information on Listeria is at <http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatory-compliance/listeria-Facility-and-Equipment-Controls> \u2022 Do not allow conditions in the retail facility that could cause the product to become contaminated. \u2022 Ensure that walls, floors, drains, and overhead

structures in the RTE deli and cooler areas are smooth, durable, easily cleanable, and in good repair. \u2022 Do not perform construction (e.g., replacing floors, walls, or ceilings) when exposed RTE product is present in the deli. Thoroughly clean\ sanitize the equipment and facilities after construction and before handling product. \u2022 Maintain tables, slicers, and other food contact surfaces so that they are easily cleanable. \u2022 Clean overhead structures as often as necessary to keep them free of condensation and ensure that sanitary conditions are maintained. \u2022 Keep water from pooling on the floor or other surfaces within the deli area. \u2022 Clean and sanitize surfaces between different types of RTE items (for example ham, seafood, and vegetables) when using the same equipment. \u2022 Ensure that grinders, dicers, scoops, or other equipment are maintained in sanitary condition. \u2022 Maintain product cases and storage at or below 41\u00b0F to slow Lm growth. USDA is an equal opportunity provider and employer. United States Department of Agriculture Food Safety and Inspection Service Guidance for Controlling Listeria monocytogenes (Lm) in Retail Delicatessens Best practice tips for deli operators The information in this brochure is taken from FSIS Best Practices Guidance for Controlling Listeria monocytogenes (Lm) in Retail Delicatessens. These are suggestions and not requirements. Retailers should be aware that the recommendations in this guidance, especially those based on the 2013 Food Code may be requirements in State, local, or tribal regulations."}],{"file\_name":"FSIS\_GD\_2015\_0016","title":"Label Submission and Approval System (LSAS): User Guide for Industry Users","num":"FSIS-GD-2015-0016","id":"156786ad74c3a4d44cf0fbc4227adae3430359efe214fe4c007d72e2e1517bb9","corpus":"fsis\_guidelines","source\_page\_url":"https://www.fsis.usda.gov/policy/fsis-guidelines","url":"https://www.fsis.usda.gov/sites/default/files/import/LSAS-Industry-User-Guide-063015.pdf","type":"pdf","n\_pages":182,"word\_count":45089,"text\_by\_page":["USDA United States Department of Agriculture USER GUIDE FOR INDUSTRY USERS V1.25 SEP 6, 2019 Label Submission and Approval System (LSAS) Application Version: 2.12.0","Label Submission and Approval System (LSAS) Industry User Guide Contact Information For assistance relating to the Label Submission and Approval System (LSAS) USDA Food Safety and Inspection Service Labeling and Program Delivery Staff Food Safety Inspection Service Phone: 301-504-0878 Email: lsas@usda.gov September 09, 2019 i","Label Submission and Approval System (LSAS) Industry User Guide Table of Contents 1 INTRODUCTION

September 09, 2019 vii", "Label Submission and Approval System (LSAS) Industry User Guide 1	
Introduction Primary Business Function The Label Submission and Approval System (LSAS) is a	
web-based software application that integrates and implements an electronic label application	
process for establishments to submit label applications. LSAS allows LPDS personnel to view,	
evaluate, and adjudicate all electronically submitted Label Application Packages (LAPs) and	
Appeal Packages (APs) efficiently and accurately. Industry users will be able to check on the	
status of their application via their web browser without calling LPDS. Also, the submitter can	
utilize the Generic Label Advisor to determine whether an application can be generically	
approved. Industry users that will be accessing LSAS include establishments, expeditors, label	
consultants, and small businesses. To use LSAS, all users are required to have an	
eAuthentication (eAuth) user ID and password. Users of LSAS will be required to have a USDA	
Level 2 eAuthentication account to access the system. USDA eAuth is the system used by USDA	
agencies to enable FSIS staff, customers, and contractors to obtain accounts that will allow	
them to access USDA web applications and services via the Internet. Purpose and Scope This	
document describes the features and capabilities of the United States Department of	
Agriculture\u2019s (USDA) Food Safety and Inspection Service (FSIS) Office of the Labeling and	
Program Delivery Staff (LPDS) Label Submission and Approval System (LSAS). The LSAS User	
Guide for Industry Users provides detailed, role-based step-by-step instructions for performing	
all industry tasks within LSAS. Personnel who use LSAS are highly trained and experienced in	
their jobs, and as such, this resource does not provide instruction on job requirements other	
than those directly involving entering data and working directly with LSAS. This document does	
provide detailed instructions on the use of LSAS. Audience The LSAS User Guide for Industry	

Users is designed for all food safety industry members who support the USDA FSIS staff in the management of food safety. Users include preparers, plant managers, agents, and label consultants. September 09, 2019 1 Chapter 1 \u2013 Introduction", "Label Submission and Approval System (LSAS) Industry User Guide Organization of the User Manual This guide is separated into sections that describe the major available functionalities and their necessary requirements for system use. A general description of each section is listed in Table 1-1. Table 1-1: User Guide Section Overviews Section Name Contents A high-level brief overview of the system, general information, and conventions used in this user guide 1 Introduction 2 System Capabilities A brief overview of the system and its capabilities. This section describes the purpose of the application and provides an overview of the system\u2019s capabilities, functions, and operation 3 System Requirements, Login, and User Profile Login instructions and a general overview of the home page 4 User Interface General introduction of the LSAS user interface 5 Menus and Functions General description and instructions on using common functionalities in LSAS 6 Generic Label Advisor (GLA) A description and instruction for using the Generic Label Advisor (GLA) 7 Submit a Label Application A description of the submission process 8 Edit a Draft Application Steps for editing an existing label application 9 View & Download Adjudicated Applications Steps to view and download a label application that has been adjudicated by LPDS 10 Handle a Returned Label Application Steps to manage a label application that was returned by LPDS 11 Manage an Appeal Steps to create and manage an appeal for a previously adjudicated label application 12 Search for Label Applications A description of the LSAS search functionalities 13 Import an Application via XML Format Steps to create a label application using the Import XML function Appendix A Glossary of Common Terms Glossary of LSAS common terms Appendix B Instructions for preparation of FSIS Form 7234 Instructions for preparation of FSIS Form 7234 Appendix C Instructions for preparation of FSIS Form 8822-4 Instructions for preparation of FSIS Form 8822-4 (Appeal form) Appendix D LSAS Tips Tips for using the LSAS system. These tips also appear in the Announcements pool on the dashboard. Appendix E LSAS Links URL links for FSIS labeling, Title 9, and other general links Appendix F FAQs Frequently asked questions regarding the LSAS application and their answers. September 09, 2019 2 Chapter 1 \u2013 Introduction", "Label Submission and Approval System (LSAS) Industry User Guide Document Conventions The following conventions are used in this guide: Convention Examples Bold and Italic text indicates the main navigation menus and their associated menu options. \u2022 From the Label Applications menu, select the Search option. \u2022 From the Administration menu, select the Ingredients option. Italic text indicates pool names, screen names, and screen section names. \u2022 LSAS displays the label application in the Appeals pool. \u2022 LSAS displays the Label Application Search screen. \u2022 LSAS displays the agent\u2019s name, address, and contact information in the Agent Information section of the Submission Information screen. Bold text indicates links and buttons. \u2022 Click the Save and Continue button. \u2022 Click the Home link. \u2022 Click the Submit button. Font enclosed in quotes indicates text for you to type verbatim or the specific value you should select. \u2022 Enter \u201cACME Foods\u201d in the textbox. \u2022 Select \u201cView\u201d from the Available Actions drop-down. Notes, Tips, and Warnings Notes provide additional clarification or explanation. NOTE: Note text appears between two blue lines. Tips provide ideas or hints that help you through a data entry form or process. TIP: Tip text appears between two yellow lines. Warnings represent a potential problem or a serious

issue. The information in warnings will help you prevent the loss or damage of data, processes, software, or hardware. WARNING: Warning text appears between two red lines.

September 09, 2019 3 Chapter 1 \u2013 Introduction", "Label Submission and Approval System (LSAS) Industry User Guide Recommendations \u2022 Avoid using your browser's buttons to navigate within LSAS. It is recommended that you use LSAS\u2019s buttons to navigate between screens.

\u2022 Save your work periodically. Safeguards, put in place by USDA, close applications and log you out of them after a period of inactivity. \u2022 LSAS makes use of messaging and comments fields for communications between LPDS and external industry users. Acronyms and Abbreviations This section provides a glossary of acronyms that may be used in this user guide.

OCIO	Office of the Chief Information Officer
OPPD	Office of Policy and Program Development
OPEER	Office of Program Evaluation, Enforcement and Review
PHIS	Public Health Information System
USDA	United States Department of Agriculture
XML	Extensible Markup Language

September 09, 2019 4 Chapter 1 \u2013 Introduction", "Label Submission and Approval System (LSAS) Industry User Guide Notes Throughout this guide, there will be many label application examples used. The author has gone through great effort to minimize the possibility of using branded names, establishment numbers, approval numbers, and any other relevant FSIS Label Application Form 7234 information. If such match should occur, then it was purely coincidental.

September 09, 2019 5 Chapter 1 \u2013 Introduction", "Label Submission and Approval System (LSAS) Industry User Guide 2 System Capabilities The USDA FSIS LPDS develops and provides labeling guidance, policies, and inspection methods, and it administers programs to protect consumers from misbranded and economically adulterated meat, poultry, and egg products to ensure that all labels are truthful and not misleading. Labeling includes all forms of product identification, health-related claims, net weight, species identification, and nutrition. LSAS is a web-based software application that integrates and implements an electronic label application process for establishments to submit label applications and appeals. Through LSAS, LPDS personnel will view, evaluate, and adjudicate all electronically submitted LAPs and APs efficiently and accurately. An adjudicated LAP\u2019s results and status will appear on the user\u2019s home page. Using LSAS, LPDS will be able to process label applications more efficiently. The required functionalities for this system include submitting label applications via the web, querying for a label application\u2019s status and information, downloading LAPs and supporting documents to a portable format, and exporting search results to a spreadsheet of submitted LAPs. The LSAS application serves as a searchable database when seeking information about products or establishments. Label information includes product identification, special claims, processes, geographical origin claims, guarantees, net weight, ingredient list, species identification, and nutritional information. LSAS provides a central tracking system for establishments and LPDS leadership. To a certain extent, LSAS replaces almost all paper-and email-based processes. Purpose The LSAS application provides the following benefits: \u2022 Establishments can submit applications and supporting materials via

and irrevocable. You may not rely on any statements or informal policies purporting to provide you with any expectation of privacy regarding communications on this system, whether oral or written, by your supervisor or any other official, except USDA's Chief Information Officer. \*\*

Your progress through these steps will be displayed on the left side navigation menu .. Click Next to continue. Click Cancel to exit the wizard. All modifications will be canceled. access to a different profile, or create a new profile. If you have any other LSAS browser  
windows or tabs open with a different profile selected, PLEASE CLOSE 11-IEM. Those windows  
or tabs will NO LONGER BE VALID after selecting a new profile. LSAS Training 1 LSAS Training 2  
LSAS Training 3 LSAS Training 4 Submit Label Submission and Approval System (LSAS) Industry  
User Guide LSAS User Profiles Once a user is granted access to LSAS, LSAS requests the user to  
select his or her Profile. Figure 3-10 illustrates the Select a Profile screen. Profiles can be  
created by the user. All that is required is a name for the organization or establishment.  
Organizational profiles are essentially label application containers. A user will always be logged  
in under a particular profile, and any label applications he or she submits while logged in under  
that profile belong to that profile. It is possible to have more than one profile. As a general rule,  
a single profile should not be used for multiple establishments that are for different  
organizations. A new profile should be created for each establishment. However, a single  
profile can have multiple establishments, but this should be limited to cases in which all of the  
establishments fall under the same parent organization. In order to continue to the LSAS home  
page, you must select a profile from the list. Select the desired profile, and then click the  
Submit button. Next, confirm your selection. Figure 3-10: Select a Profile Screen After selecting  
a profile, LSAS displays the LSAS home page, aka the Dashboard screen. This is the user  
interface from which you will initiate your day-to-day activities in LSAS. September 09, 2019 19

Manage Sharing Manage Establishments Label Applications \u2022 Search Or,eate Generic Labeil Advisor Imp\u25a1 rt Ap;plicatio n>S Status Check . Apptication # 11 Check l Label Submission and Approval System (LSAS) Industry User Guide Profile Users, Sharing, and Establishments On the home page, the user has additional options to manage users, sharing, and establishments, as illustrated in Figure 3-13.

Figure 3-13: User's Profile Options The Manage Users option is especially valuable when an establishment wants to delegate additional resources for submitting or managing a label application. An establishment\u2019s first LSAS user will generally be the initial contact person. This person will likely be the administrator of any profiles associated with the establishment. It will be the establishment\u2019s responsibility to manage all users associated with that establishment, independently of LPDS. Through LSAS\u2019s profile management function, the establishment\u2019s newly assigned administrator can easily add\assign other establishment resources as LSAS users. These users will be assigned an LSAS role as associates within the establishment. Additionally, in the situation where the establishment farms out its label application process, the

establishment's administrator, using LSAS's profile tool, can create user profiles for agents/expeditors. Then, the establishment can share certain label applications with a designated agent/expeditor. Also, its LSAS privileges may have limited functionality. The Manage Sharing option allows a user to share his applications with another user. As mentioned in the preceding paragraph, an establishment can share specific applications with its agent once the agent has permission to access LSAS. The Manage Establishments option allows a user to add establishments to his profile. For example, a major corporation will have multiple subsidiaries, so there will be a need to create a separate profile for each of the subsidiaries. This option provides the establishment a way to include its establishment numbers and allows LSAS to easily associate a user with his establishment's number and address. The establishment number and address is a required field in the Form 7234. LSAS provides a tool to import establishment information directly from PHIS. ..... I Submit I Label Submission and Approval System (LSAS) Industry User Guide Manage Users A user can request access to a specific user profile. The requestor uses the Request Access function to ask for access privileges to a LAP. If a user has requested access, his username will appear on the Profile Users screen (Figure 3-14) of the user who currently has access to the profile (the requestee). The requestee will then have the option to approve or deny the request. Using the Manage Users option, the user receiving the request (the requestee) will approve or deny the request. Figure 3-14 shows the Profile Users screen with profile access requests from two other Submitter users. These new requests will appear in green text with a status of \u201cPending\u201d until the requestee either approves or denies the request. Figure 3-14: Profile Users Screen If approved, the requestor can be assigned as an Administrator or Associate. Associate An associate is an LSAS user assigned by his organization's administrator to perform label submission tasks, including checking label status and viewing LAPs. Administrator An administrator is the main contact person representing a company or establishment. The main role of the administrator is to grant access to LSAS to users within his organization, in addition to all of the associate's tasks. Select the appropriate value (Associate, Administrator, or Denied) using the drop-down list associated with each request for access: Figure 3-15: Profile Users Screen \u2013 Select \u201cAssociate\u201d Option September 09, 2019 26 Chapter 3 \u2013 System Requirements, Login, & User Profile", "Label Submission and Approval System (LSAS) Industry User Guide What to Do If a User Is Leaving or Has Already Left an Establishment If you are leaving an establishment or firm, send an email notification to the LSAS Administrator: lsas@fsis.usda.gov. Specify whether you are leaving your current position permanently; or, if you will be employed as a Submitter for the new establishment or firm. At a minimum, provide your name, establishment name and number,

user profile name (located on the upper left of the main LSAS screen in the left navigation menu), phone number, and if applicable and known the name of the person who will assume responsibility for the establishment's label applications in LSAS. The LSAS Administrator will set your account accordingly. To deactivate your LSAS account, send an email or letter (dated and signed on official letterhead) to the LSAS Administrator, providing the following information: 1. First Name, Last Name (as registered with eAuth) 2. Profile name(s) as established in LSAS (located on the left navigation panel of your dashboard) 3. Establishment Name and Number 4. Reason for deactivation 5. Effective Date 6. Contact information (phone and email address) To request access to another user's profile for a user who is no longer with the establishment or firm, send an email or letter (dated and signed on official letterhead) to the LSAS Administrator providing the following Information: 1. First and last name of the previous user (original submitter) whose profile you need to access 2. The previous user's User Profile name(s) as established in LSAS 3. Confirmation that the previous user account should be deactivated 4. The reason(s) the previous user's account should be deactivated 5. A listing of the previous user's application/approval number(s), product names, and establishment number(s) 6. Your first and last name 7. The relationship you hold with the previous user 8. Your User Profile name as established in LSAS (located on the left navigation panel of your dashboard) 9. This pool is visible to all users, regardless of their user role in LSAS. Figure 4-4: Announcements Pool September 09,

2019 47 Chapter 4 \u2013 User Interface", "Application Messages Application Product Name Creation Created By Message # Date Crispy This submission is for a new label for a brand new product We 91047407 Breaded 611012016 01-J.Williams, will most likely be changing, the label soon, though\_ We submitted I View I Chicken (Submitter) this as \"Sketch\" but we are not sure if it should have been sent as Nuggets \"Temporary\"? Please let us know. Thank you! This LAP is being returned because the text entered for the 09-J.Canavan, \"Processing Procedures\u00b7 section included the wrong, type of info. 91047401 Turkey 619\|/2016 (Sr.Techical (The Submitter entered ingredient information rather than I View I Tetrazinni Staff) processing information.) Please correct and resubmitthe application. Label Submission and Approval System (LSAS) Industry User Guide Application Messages Using LSAS Messages, LPDS technical staff can communicate with industry users regarding any issues for a particular label application. The Application Messages pool on the Dashboard screen will display the most recently created message for each of your label applications (Figure 4-5). This pool is visible to all users, regardless of their user role in LSAS. LPDS will see and respond to any messages you create for your label applications. Figure 4-5: Application Messages Pool For submitters, the Application Messages pool displays the following types of records: \u2022 Messages: The most recent message for a label application will appear in the pool. If a label application has multiple associated messages, only the latest message for the label application will appear in the pool. Messages that were created more than 15 days ago will not appear in the Application Messages pool on the dashboard; however, they can still be viewed on the Messages screen that is accessed via the Available Actions menu, as discussed in the Messages section on page 83. \u2022 Vet EC comments: If an EC application has been vetted by an EC Gatekeeper, any comment that the EC Gatekeeper entered will appear in the pool. If you click the View button for an application in the Application Messages pool (Figure 4-5), LSAS will display all of that application\u2019s messages in a new window. For example, if the user clicks the View button for the second message shown in the image above, LSAS will display the Label Application Message screen for the associated label application (see Figure 4-6 on the next page); this screen shows all the messages that currently exist for the label application. The submitter may appeal a Sketch Modified label application. Normally, a returned label application is resubmitted. You can create an appeal for a label application only if LPDS has adjudicated the application to one of the following statuses: \u201cSketch Modified,\u201d \u201cReturn,\u201d \u201cTemporary,\u201d or \u201cExtension of Temporary.\u201d An appeal cannot be created for a label application that LPDS adjudicated as \u201cSketch.\u201d The \u201cCreate Appeal\u201d action does not appear in the Available Actions drop-down list if you have already used up all of the appeal requests (Appeal Levels 1, 2, and 3) for the selected label application. You can create an appeal for a returned application only if the application includes the same, unedited data as the original submission. If LPDS returns a label application, and then you edit the returned application, you will not be able to create an appeal for the edited application. If you edit a returned application, you can resubmit the application with the

updated information, but you cannot create an appeal. Once submitted, the appeal is evaluated by an Appeals Handler, a senior level LPDS personnel member. Each appeal will be reviewed to determine whether the reason submitted by the submitter is valid. The Appeal Handler has the option to approve the appeal. Alternatively, the handler can reject the appeal and send the label application back to the submitter. The submitter, upon reviewing the new decision, has the option to reappeal this decision. When a subsequent appeal is submitted, it is escalated to a higher priority\level and will be reviewed by a higher authority in LPDS. If an appealed LAP is approved, then LPDS will change the status to \u201cApproved\u201d. LPDS\u2019s decision will appear in the submitter\u2019s Dashboard. Effective January 6, 2014, FSIS regulation 9 CFR 412.2 streamlined the label approval process and allowed establishments more flexibility. The generic approval category was expanded so that establishments could use certain labeling without prior FSIS approval. LSAS has incorporated the regulations into a wizard, the Generic Label Advisor, to allow the

submitter to determine if a label can be generically approved. The following conditions prohibit a label application from being considered for generic approval:

- \u2022 The product was produced under a religious exemption.
- \u2022 The label is for export only with deviations from domestic requirements.
- \u2022 The label is for temporary approval.
- \u2022 The label bears a special statement or claim that was not previously approved.
- \u2022 Product Type is \\"Egg\\Other\\".
- \u2022 The Product Type is an exotic species under voluntary inspection.

NOTE: The Product Type \u201cEgg\\Other\u201d includes exotic species. If the Generic Label Advisor (GLA) determines that a label can be generically approved, LSAS will generate a certificate for the establishment to file with its labeling records. If the wizard determines that the label cannot be generically approved, it will display a message stating so. The wizard will also display a Go To Label Application button that you can click to open the LSAS label application screens for the normal submission process.

1. To start the GLA, click the Generic Label Advisor menu option in the left navigation panel.

-----i Submission Information 7234 Summary mberfor and Label Submission and Approval System (LSAS) Industry User Guide 7 Submit a Label Application Label Application Submission Process LSAS was designed to provide the submitter a step-by-step process for completing the 7234 application. The information requested is directly inherited from Form 7234. Some additional information is requested to streamline the submission process. A label application consists not only of the Form 7234, but also of a label image(s) and any supporting documentation. LSAS includes functionality to upload any label image and supporting document(s). Once a label application has been submitted, LPDS personnel will review and evaluate it. It is important to include all relevant information and documentation, i.e., special claims, so as not to delay the process and have the LAP returned. The actual application process consists of ten screens, as shown in Figure 7-1. As the Submitter completes all the required fields and saves each screen, LSAS will proceed to the next step (screen). If the submitter does not complete each screen in the process, LSAS will display an error message. Figure 7-1: Go To Drop-down for Accessing the Form 7234 Screens At the end of the process, the Submitter submits the application to LPDS. LSAS displays an acknowledgement that the submission was accepted and assigns an application number for future reference. LAPs will be neither evaluated nor adjudicated unless they are received by LPDS. Once received, LPDS will evaluate the label application and provide an adjudication decision. LSAS will send an email notification to the submitter\u2019s specified Firm or Agent email address to alert them of LPDS\u2019s adjudication decision. NOTE: Email notifications of adjudication decisions will be provided only for those applications that were submitted electronically via LSAS. The sections that follow guide the Submitter through the 7234 application process. Additional Information Specific to Egg Products: When the submitter checks the status of the application and it is approved, then the attached PY Form 221 (Egg Label Notice) will also be available for reference. The submitter can view the form and see the egg approval number. If the application is ever resubmitted, then the submitter can enter this number as the \u201cprior egg approval number\u201d if it is still appropriate for the new application. The prior egg approval number is provided on the Egg Label Notice if the label application was approved\u201d September 09, 2019 105 Chapter 7 \u2013 Submit a Label Application", "If you wish to designate extraordinary circumstances for this product, please check the following box: \u25a1 I certify that this label meets the FSIS, Extraordinary circumstances. poricy. Label Submission and Approval System (LSAS) Industry User Guide \u2022 Voluntary Review \u2013 If you believe your label application does not require review by FSIS because it complies with generic labeling requirements, then select \u201cYes\u201d for the question: \u201cAre you requesting a Voluntary Review of a submission which can be generically approved?\u201d o You cannot answer \u201cYes\u201d to the Voluntary Review question if your label application is for an egg product. o You cannot answer \u201cYes\u201d to the Voluntary Review question if you selected the Extraordinary Circumstances checkbox. If you are not sure whether your label application meets the minimum requirements to be considered for voluntary review, you can use the Generic Label Advisor Wizard to help you determine whether your label is a valid candidate. For complete details on the GLA Wizard, please see the Generic Label Advisor section on page 95. \u2022 Extraordinary Circumstances \u2013 If you believe your label application merits expedited evaluation by FSIS, select the Extraordinary Circumstances checkbox. The blue, underlined text is a hyperlink to

FSIS's extraordinary circumstances policy. If you are unsure whether your application qualifies for extraordinary circumstances, click the link to access the policy information to aid you in your decision. All label applications designated as having extraordinary circumstances will be vetted to validate the request. See the Extraordinary Circumstances section on page 129 for more information. The Extraordinary Circumstances checkbox can only be selected on the first (original) submission of a label application. If you select this checkbox on an original submission, then you cannot un-check the checkbox on any subsequent resubmission of the same label application. Likewise, if you did not select the EC checkbox on the original submission, then you cannot select it for a resubmission of the same label application. The same vetting decision that LPDS applied to the original submission will automatically be applied to any resubmission.

o You cannot select the Extraordinary Circumstances checkbox if you answered "Yes" to the Voluntary Review question.

6. To continue to the next screen, click the Save and Continue button. LSAS opens the Special Claims Information screen (Figure 7-6).

Label Submission and Approval System (LSAS) Industry User Guide LSAS will then search in its Master Ingredient List for the entered ingredient(s). After you have entered all the ingredient names, click the Search button. \u2022 If an ingredient is found, then the Product Formula screen displays a new table with the ingredient included. \u2022 If an ingredient is not found in the Master list, then a message will be displayed, as shown in Figure 7-12. LSAS will display three possible options for the ingredient: Make Corrections, Discard, and Add Anyway. Figure 7-12: Ingredients Not Found Message 20. Make the appropriate selection for each ingredient that was not found in the Master list: \u2022 If the ingredient is correctly spelled, then click the Add Anyway button. LSAS adds the new ingredient(s) to the list. \u2022 If you need to make

corrections to the spelling of an ingredient name, click the Make Corrections button. You will then be given an opportunity to re-enter the ingredient name. If you wish to remove the ingredient, click the Discard button. In Figure 7-13 below, the submitter chose to add the ingredients that were not found in the master list. Any ingredient that was found in the master list is displayed in all capital letters. Any ingredient that was not found in the master list will be in lowercase. Figure 7-13: Ingredients Add Anyway 21. For each ingredient, enter either the ingredient weight or percentage in the right-most column. Ingredient values must be positive numbers. Values of <0 or >1 are not allowed. Decimal values are permitted.

Extraordinary Circumstances\u2022 Other | Upload | | Browse ... \_ Label Submission and  
Approval System (LSAS) Industry User Guide Extraordinary Circumstances Current LPDS process  
provides establishments with a special service called Extraordinary Circumstance (EC). The EC  
service alerts LPDS that an establishment requests expedited attention on a label application.  
The Product Information screen provides a checkbox for the submitter to indicate this request  
(Figure 7-26). Figure 7-26: Product Information Screen \u2013 EC Checkbox If a submitter  
selects the EC checkbox on the Product Information screen, then documentation to support the  
EC claim must be attached to the application. The Label Documentation screen will display an  
additional \u201cExtraordinary Circumstances\u201d value in the documentation type drop-  
down, and the value will be shown with an asterisk to indicate that it is required (Figure 7-27).  
Figure 7-27: Label Documentation Screen \u2013 Required EC Documentation September 09,  
2019 129 Chapter 7 \u2013 Submit a Label Application", "Label Submission and Approval System  
(LSAS) Industry User Guide LPDS Vetting Process for EC Applications LPDS has a vetting process  
to determine the legitimacy of each EC request. The vetting stage occurs prior to the evaluation  
and adjudication process. The purpose of the vetting process is to evaluate whether the  
circumstance is truly valid. Selection of \u201cExtraordinary Circumstances\u201d is not a  
means to \u201cresubmit\u201d a returned application. The selection of \u201cExtraordinary  
Circumstances\u201d should only be chosen if the product has been retained ("tagged") by  
program personnel at official establishments or when there is some other unforeseeable  
impediment to movement of the product, and a temporary label approval would remove the  
impediment. For complete policy guidance, see the FSIS website:

<http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatory-compliance/labeling/labelingprocedures/procedures-evaluating-labeling> See Tip 5 posted in  
the Announcements pool on how to resubmit a returned application to LPDD. When a  
submitter specifies that an application is an EC application by checking the extraordinary  
circumstances checkbox, LSAS will redirect the application to the EC Gatekeeper. The EC  
Gatekeeper confirms or denies the submitter\u2019s EC request. Any requests that are  
confirmed will be given priority review. Notes on Resubmitted EC Applications: The system shall  
allow a submitter to identify a label application as an EC application only on the original  
submission. \u2022 If the submitter did not select the EC checkbox on the original submission,  
then LSAS will not allow the Submitter to select the EC checkbox for any subsequent  
resubmission \u2022 If an EC request was approved for an original submission, then the  
submitter will not be allowed to uncheck the EC checkbox for any subsequent resubmission.  
\u2022 If an EC request was denied for an original submission, then the submitter will not be  
allowed to check the EC checkbox for any subsequent resubmission. September 09, 2019 130

Other CertifiedNerified . Natural\Organic Browse ... I Upload I Label Submission and Approval  
System (LSAS) Industry User Guide Special Claims Some label applications have special claims  
that require approval before they can appear on a product label. A submitter can enter any  
special claims on the Special Claims Information screen. For more information, see the Special  
Claims section on page 107. If a submitter enters any special claims for a label application on  
the Special Claims Information screen, then documentation supporting the special claim(s)  
should be attached to the application. The Label Documentation screen will display the  
submitter\u2019s special claim selections in the documentation type drop-down to indicate  
that this documentation should be included with the application. Example: A submitter selected  
the \u201cCertified\Verified\u201d and \u201cNatural\Organic\u201d claims on the Special  
Claims Information screen. The Label Documentation screen displays the selected claims in the  
documentation type drop-down. September 09, 2019 131 Chapter 7 \u2013 Submit a Label

----- Application Locked Label Application SULLILLARY-----< Application Number | Barco de 91047600 Name of Product: Submitted By: Current Status: Current Status Set By: Submission Type: Breaded Chicken Tenders with Honey Mustard Sauce Draft 01-J.Williams, (Submitter) at 7122\2016 9:53:56 AM Web Manage this application Lock Information-----, Looking User: 01-J.Williams, (Submitter) Last Accessed At: 7122\2016 9:58:27 AM You already have a lock on this label application. This can occur if your browser or computer crashed, or if you have the application open for editing in a different window, tab, browser, or computer. By submitting this form you may release this lock. CAUTION: You will no longer be able to commit any unsaved information in any of these other locations and must re-open the label application for editing. Submit Label Submission and Approval System (LSAS) Industry User Guide NOTE: LSAS may display an Application Locked screen when a user attempts to open a LAP. This occurs whenever another user is currently editing the application, or for reasons indicated in the informational panel. If this screen appears and you wish to continue opening the application, click the Submit button. Then click the Confirm button to continue. Figure 8-3: Application Locked Screen September 09, 2019 135 Chapter 8 \u2013 Edit a Draft Application", "Label Submission and Approval System (LSAS)

Industry User Guide 9 View & Download Adjudicated Applications When a label application has been adjudicated, the submitter can locate the label application in either the Adjudicated Applications pool or the Returns and Rescinded Applications pool. If the submitter wishes to view the adjudication details, he can select \u201cSummary\u201d from the Available Actions drop-down. Scroll to the bottom to view comments entered by the LPDS. If the submitter wishes to download a copy of the approved label, select \u201cDownload\u201d from the Available Actions drop-down (see Figure 5-5). The Label Documentation screen opens and allows the submitter to download all documents associated with the label, including annotations made by LPDS. During the download, the submitter can save them to his local machine. How to Print An Adjudicated Label with Annotations (Stamps, Modifications, etc.) Select all the documents that you want to include in the download. Be sure to check the \u201cInclude Annotations\u201d checkbox. After downloading, in the Adobe Reader window, from the Print menu under \u201cComments & Forms\u201d, select \u201cDocument and Markups\u201d. Then proceed to print. My application was returned to me. Where do I find the reason(s) it was returned? You will find the reason(s) for the returned submission by viewing the Label Application Comment field located at the bottom of the Summary. Select your returned application from the Returns and Rescinded Applications pool. Then, from the Manage Application screen, select \u201cSummary\u201d from the Available Actions drop-down. On the Summary screen, scroll to the bottom of the page to view the Label Application\u2019s comments. I received a Sketch Modified label. Where do I find the explanation of the modifications that were made? Reason(s) for the modifications can be located on the annotated label image, application form, and\|or in the Comment field section of the Summary screen. September 09, 2019 136 Chapter 9 \u2013 View & Download Adjudicated Applications", "Label Submission and Approval System (LSAS) Industry User Guide 10 Handle a Returned Label Application When a label application is adjudicated as Returned, the reasons are usually due to insufficient information or the submitted information is not readable. The submitter should view the label application\u2019s Summary screen to see the reason(s) LPDS returned the application. How do I resubmit my returned application to LPDS? Select your returned application from the Returns and Rescinded Applications pool. Then, from the Manage Application screen, select \u201cEdit\u201d from the Available Actions drop-down. The Edit function allows you to make corrections, additions, deletions, etc. You can navigate to the specific area of the application by using the Go To function in the upper right corner of the dashboard. Be sure to save your changes. Finally, using the Go To function, select \u201c7234 Summary\u201d. On the Summary screen, review and submit your application. When the application is resubmitted, it will appear in the LPDD Pool as a resubmittal. NOTE: If you need to replace documents in a returned application, first remove the documents that were included in the original submission, and then upload the new\|corrected documents. August 15, 2019 137 Chapter 10 \u2013 Handle a Returned Label Application", "", "Label Submission and Approval System (LSAS) Industry User Guide 11 Manage an Appeal The purpose of the appeals process is to allow the submitter to appeal an LPDS decision, modification, or denial. The \u201cAppeal\u201d function should be used only if the establishment disagrees with a specific modification or reason for rejection. The creation of an appeal is not a means to \u201cresubmit\u201d a returned application. For example, if an LPDS reviewer returns a label application because the label image is not legible, the Submitter should not appeal this

decision, but should instead resubmit the label application with an updated, legible label image. See Tip 5 posted in the Announcements. LSAS provides a means for the submitter to appeal LAPs via the "Create Appeal" action in the Available Actions drop-down on the Manage Application screen. This action is discussed in complete detail in the Create Appeal section on page 71. For additional guidance, see the instruction page for Form 8822-4 in Appendix C on page 172.

September 09, 2019 139 Chapter 11 "Manage an Appeal", "Submitter User: 01-J.Williams, (Submitter) Role: Submitter Profile: Plumrose -Booneville I Switch profiles Submit Label Applications ... Search Or,ate Generic La be! Advis" Imp" rt A~licati" n.s Status Check ... Ap;p[tcati[Olil # III Check I Label Submission and Approval System (LSAS) Industry User Guide 12 Search for Label Applications The LAP Search function, accessible from the left navigation menu, allows you to search the LSAS database for labels based on the criteria entered in the search fields. To access the Label Application Search screen, click the Search menu option from the Label Applications menu on the left side of the home page.

March 14, 2019 140 Chapter 12 "Search for Label Applications", "Label Submission and Approval System (LSAS) Industry User Guide The Label Application Search screen, illustrated in Figure 12-1, is the interface used to search the LSAS database for all LAPs associated with the establishment(s) of the logged-in user.

March 14, 2019 141 Chapter 12 "Search for Label Applications", "Label Submission and Approval System (LSAS) Industry User Guide Search Fields The search fields available on the Label Application Search screen include the following fields. A short description of these fields can be found in Appendix A.

Date Fields: Enter desired date(s) or date ranges using the calendar icon ( ) to select date entries from a calendar, or by entering them manually in the mm\dd\yyyy format.

"Earliest Submission Date ; Latest Submission Date" "Earliest Status Date ; Latest Status Date" "Earliest Expiration Date ; Latest Expiration Date" "Earliest Appeal Adjudication Date ; Latest Appeal Adjudication Date"

Textbox Fields: Textbox fields allow a maximum of 30 characters.

"Establishment Number (see NOTE below)" "Approval Number" "Name of Product" "Name of Firm" Users can enter the percent symbol (%) as a wildcard in textbox fields to perform searches on partial text strings. Examples of wildcard searches in the Name of Product field include:

- "%hot dog - All label names ending in hot dog will be found."
- "hot dog%" -All label names beginning with hot dog will be found
- "%hot%dog%" -All label names that contain the words hot and dog will be found
- "hot dog" -Only label names with the exact name of hot dog will be found

NOTE: Although the Establishment Number field is a textbox, it is not necessary to use the % character to perform searches on partial values. For example, if you know the number starts with M15, you can enter just those three characters and the search results will include all label applications that are associated with an establishment that has M15 anywhere within the Establishment Number. The characters could appear at the beginning, the end, or anywhere within the Establishment Number in the search results.

NOTE: The Approval Number is the bar code number. All labels in LSAS are identified using the Approval Number.

Drop-down List Fields: Drop-down list fields allow you to select a single value from a list. Click the downward facing arrow to the right of the field label name to display the complete list, then click the desired value.

"Appeal Status" "Resubmission Listbox Fields: Listbox fields"

allow you to select one or multiple values simultaneously. To select multiple values, press and hold down the Shift key while you click on each of the desired values. \u2022 Application Status \u2022 Approval Request Type \u2022 Type of Product After entering or selecting your search criteria, click the Search button to initiate the search. (Alternatively, you can press the Enter key on your keyboard to initiate the search.) The screen displays all LAPs that meet the following search parameters: \u2022 Application Status = \u201cTemporary\u201d \u2022 Name of Product = \u201cham%\u201d (find all LAPs that have \u201cham%\u201d anywhere in the product name) \u2022 Resubmission = \u201cYes\u201d Figure 12-2: Label Application Search Results Screen The Label Application Search Results screen (Figure 8-2) contains features to sort search result data, and to view additional pages of search results. Search Again Click Search Again to return to the Label Application Search screen to perform a new search. NOTE: If you are currently on the search results screen and would like to view your original search criteria, do not click the Search Again button, as this will clear your search criteria. Instead, click on your browser\u2019s Back button. LSAS will display the Label Application Search screen with your original search criteria. Records field Displays the total number of label applications found in the search request. For additional pages, click the NEXT button. Column Headers Sort the search results list by a selected column. Click a column heading once to sort ascending, twice to sort descending. For example, if you wish to order the LAPs by their application numbers, click the App# column heading. The LAPs will be ordered from the lowest to the highest number. Click again, and the LAPs will be ordered from highest to lowest. March 14, 2019 143 Chapter 12 \u2013 Search for Label Applications", "Label Submission and Approval System (LSAS) Industry User Guide If there are more search results than can be displayed on a single page, two additional options will appear below the results list: Next The Next button will be visible\available only if there are too many search results to display on a single page. Click the link of the desired page to open the associated page of search results. Items per Page Select a value from the drop-down list to adjust the number of search result items displayed per page (10, 25, 50, 75, or 100). The default is 50. View a LAP from Search Results The search results screen (Figure 12-2) includes a feature that allows you to view a LAP in detail. From the search results, click on an application number. LSAS displays the Manage Application screen for the selected application. \u2022 To view the

LAP\u2019s Form 7234, select \u201cView\u201d from the Available Actions drop-down, then click Select. \u2022 To view the 7234 application data, select \u201cSummary\u201d from the Available Actions drop-down, then click Select. Depending on your role in LSAS, the options that appear in the Available Actions drop-down will vary. March 14, 2019 144 Chapter 12 \u2013 Search for Label Applications", "Label Submission and Approval System (LSAS) Industry User Guide 13 Import an Application via XML Format In some cases, the establishment may delegate the label submission task to an outside contractor, agent, or expeditor (aka an \u201cAgent\u201d in LSAS). In such cases, the Agent may use LSAS\u2019s Import XML process to quickly create label applications in LSAS without having to enter the information manually on the multiple input screens discussed in Chapter 7 -Submit a Label Application. The XML Import process is particularly useful when the establishment has an internal electronic data repository from which the raw data for a label application can be pulled and then inserted into an XML file. Once the XML file has been prepared, the Agent can initiate the import process which will read the XML file to automatically create an electronic label application in LSAS. Download the Schema In order to create the XML file, the Agent must first obtain the schema which specifies the required format for the XML data fields and values. The schema is an .xsd file that is available for download within LSAS. 1. Select Import Applications from the Label Applications menu in the left panel. Label Applications - Sea1ch ere te Generic Label Advisor \"\\"ort Appicatio ns, sta1us Checi.: ... Application# I II Checik I Label Import Download Schema Se[ec]t an X!ML fite to upload\* Browse ... 2. LSAS will display the Label Import screen (Figure 13-1). Figure 13-1: Label Import Screen 3. Click the Download Schema link. 4. You will be prompted to open or save the schema file. Select Save (or Save As) and save the file to your local machine. September 09, 2019 145 Chapter 13 \u2013 Import an Application via XML Format", "Label Submission and Approval System (LSAS) Industry User Guide Create XML Import File from XSD Schema In order for the import to succeed, the XML data must be in a valid format accepted by LSAS. Refer to the next section, LSAS XML Import Guidelines for Industry Users, for complete details on the requirements for the values that must be included in the XML file for the import process to be successful. When the label data in the XML file is formatted per the LSAS schema, the agent can import the XML into LSAS to create a label application that can be submitted to LPDS for review and adjudication. Note: If the Agent utilizes a separate software application for handling label applications, he must configure the in-house system to export label information using the XML schema so that it is readable by LSAS. Recommended XSD-to-XML Conversion Tool: Multiple sites online offer free XSD-to-XML conversion tools. Different sites will generate differently-formatted XML files. The conversion tool at the following site has been tested and verified to generate the XML file in a format that is accepted by LSAS. Online XSD to XML generator XSD2XML website\*: <http://xsd2xml.com/> Note: This conversion tool will only create the raw XML file in the appropriate format for LSAS; it does not enter the actual values required in the label application. You will need to edit this auto-generated XML file to include the label application data. \*USDA-FSIS has no affiliation with this site and does not guarantee the site\u2019s performance or availability. September 09, 2019 146 Chapter 13 \u2013 Import an Application via XML Format", "Label Submission and Approval System (LSAS) Industry User Guide LSAS XML Import Guidelines for Industry Users Default String Value for Text Fields The default string value in the generated XML file will vary depending on how you convert the XSD schema to XML. For example, if you use the online tool

from <http://xsd2xml.com>, then the default string in the XML file might be \"str1234\" while a different tool, located at <https://devutilsonline.com/xsd-xml/generate-xml-from-xsd>, might set all default string values to \"string\". This document will generally indicate \"str1234\" as the default XML string value. Please be aware that your particular XML file may have a different default string value, and adjust your steps accordingly.

**Required Fields** If the field description in this document indicates that a field value is required on the LSAS Web UI, but not required in the XML Import file, then you have the option of entering a value in the XML file or waiting to enter it via the UI. (LSAS will not prevent you from uploading the XML file if you did not enter a value for the field in the XML file.) If you did not enter a value for a field in the XML file, then, after importing the XML file, you must enter a value for it via the LSAS Web UI. LSAS will not allow you to save or submit the application via the UI until you have entered a value.

**Special Characters** In most cases, if you need to enter a special character into one of the text fields in the XML file, you can do so without having to add any special formatting in the XML file. However, there are five characters that require special formatting in the XML file in order for the import process to complete successfully. For these five characters, you can choose either of the methods shown in the table below (entity replacement or numeric replacement).

Original Character	XML Entity Replacement	XML Numeric Replacement
< (less than operator)	&lt;	&lt;
> (greater than operator)	&gt;	&gt;
\u201c (double quotes)	&quot;	&quot;
& (ampersand)	&	&
\u2018 (apostrophe \ single quotation mark)	&apos;	&apos;

No Required via manual\|web entry? No If the selected Type of Product is \u201cEgg\u201d and the application was previously approved, then the prior egg approval number should be provided using the number on the previously approved Egg Label Notice (PY Form 221). The prior egg approval number is provided on the Egg Label Notice if the label application was approved. \u2022 If ProductType = \"Egg\" and you have a prior Egg Approval Number, then remove \"str1234\" from <EggApprovalNumber>str1234</EggApprovalNumber> and replace it with the prior Egg Approval Number. \u2022 If ProductType = anything other than \"Egg\", then remove \"str1234\" from <EggApprovalNumber>str1234</EggApprovalNumber>. (Leave the value blank.) 7 Label\_Meets\_FSIS\_Extraordinary\_Circumstances Required in XML file? Yes Required via manual\|web entry? Yes If you wish to designate the label application as an extraordinary circumstance, remove \"No\" from <Label\_Meets\_FSIS\_Extraordinary\_Circumstances>No</Label\_Meets\_FSIS\_Extraordinary\_Circumstances> and replace it with \u201cYes\u201d; otherwise, leave the default value of \u201cNo\u201d. If you are unsure whether your application qualifies for extraordinary circumstances, click on the following link to access the policy information to aid you in your decision: <http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatory-compliance/labeling/labeling-procedures/procedures-evaluatinglabeling> Using the manual entry process in LSAS, the Extraordinary Circumstances checkbox can only be selected on the first (original) submission of a label application. If you select this checkbox on an original submission, then you cannot un-check the checkbox on any subsequent resubmission of the same label application. Likewise, if you did not select the EC checkbox on the original submission, then you cannot select it for a resubmission of the same label application. The same vetting decision that LPDS applied to the original submission will automatically be applied to any resubmission. Likewise, using the XML Import process, LSAS will allow you to choose and enter either \u201cYes\u201d or \u201cNo\u201d for the first submission only. Any resubmitted application that is entered via the import process must have the same EC value as the original submission. 8 Is\_Voluntary\_Review Required in XML file? Yes Required via manual\|web entry? Yes If you wish to designate the label application as one that meets the

criteria for voluntary review, remove \"No\" from <Is\_Voluntary\_Review>No</Is\_Voluntary\_Review> and replace it with \u201cYes\u201d; otherwise, leave the default value of \u201cNo\u201d. If you are not sure whether your label application meets the minimum requirements to be considered for voluntary review, you can use the Generic Label Advisor Wizard to help you determine whether your label is a valid candidate. September 09, 2019 150 Chapter 13 \u2013 Import an Application via XML Format", "III Label Submission and Approval System (LSAS) Industry User Guide XSD File Field Order XML Import File Field Name & Guidelines 9 SpecialClaim Required in XML file? Yes. The value in the XML file cannot be blank. Leave the default value of \u201cNONE\u201d if the label application does not have any special claims. Required via manual\|web entry? No If you would like to enter a special claim, remove \"NONE\" from <SpecialClaim>NONE</SpecialClaim> and replace it with the name of the desired Special Claim. The selected Special Claim must be entered exactly as it appears in the .xsd schema file, including capitalization and underscores. Valid Special Claim values include: Allergen\_Statements Animal\_Production\_Breed\_Raising Certified\_Verified\_Environmental\_Green Export\_only\_Labels\_w\_deviations\_from\_Domestic\_Requirements Foreign\_Language Geographic\_Undefined\_Style Grading\_Terms Guarantees Natural\_Organic Nutrition\_Health Religious\_Exemption Other\_Claims Notes for entering multiple Special Claims: You can enter multiple Special Claims, if desired. Only one Special Claim field is displayed in the xsd schema template. If you wish to enter more than one Special Claim, then add another line using the same format. For example, enter: <SpecialClaim>Allergen\_Statements</SpecialClaim> <SpecialClaim>Natural\_Organic</SpecialClaim> 10 OtherClaimDescription Required in XML file? No Required via manual\|web entry? Required only if the \"Other Claims\" checkbox was selected \u2022 If you have a SpecialClaim of \u201cOther\_Claims\u201d then remove \"str1234\" from <OtherClaimDescription>str1234</OtherClaimDescription> and replace it with your description of the \"Other Claim\" \u2022 If you do not have a SpecialClaim of \u201cOther\_Claims\u201d then remove \"str1234\" from <OtherClaimDescription>str1234</OtherClaimDescription>. (Leave the value blank.) What ingredients have changed? What is in the product that is not on the label? What process has changed?) Maximum limit is 2000 characters . ..... 'I I verify that I have followed the instructions for completing this Temporary Application request \u2022 Label Submission and Approval System (LSAS) Industry User Guide \u2022 Product Formula screen \u2013 Select the verification checkbox. You can Save the ingredient information, but you can\u2019t Save & Continue without the box being checked. Additionally, the box must be checked before submitting the application. Additionally, for Temporary and Extension of Temporary applications only), the following fields require entry or selection: \u2022 Approval Information screen \u2013 Enter the reasons you are seeking temporary approval in the textbox provided and select the checkbox to confirm you have followed the instructions for completing a temporary application. This checkbox must be selected for all temporary applications. 9. Navigate to the 7234 Summary screen, review the label information, and click Submit Application. September 09, 2019 168 Chapter 13 \u2013 Import an Application via XML Format", "Label Submission and Approval System (LSAS) Industry User Guide Appendix A: Glossary of Common Terms Administrator: The term \u201cAdministrator\u201d can apply to different types of LSAS users: \u2022 LPDS Administrator (LSAS role = Administrator): An internal LPDS user who has authority to access all

functions within the system. \u2022 Organization Administrator (LSAS role = Submitter): An Organization Administrator is the main contact person representing a company or establishment. The main role of the Organization Administrator is to add or remove users accessing LSAS within their organization, in addition to all of the associate\u2019s tasks. Agent: An individual or organization that acts on behalf of an establishment for the purpose of submitting a label application. Appeal Status: An appeal may be Under Appeal, Appeal Approved, or Appeal Denied. Approval Number: An Approval Number is assigned to a label application that has been adjudicated and approved. Prior to adjudication, the same number is used as the Application Number to uniquely identify the label application within LSAS. The Approval Number replaces the barcode number. Approval Request Type: The submitter can request sketch, sketch modified, temporary, and extension of temporary. Application Status: A label\u2019s status in LSAS (Received, Pending, Returned, Sketch, or Sketch Modified) Area of Principal Display: The size of the label on the product. Associate: An associate will be an LSAS user assigned by the organization\u2019s administrator to perform label submission tasks, including checking LAP status, viewing LAPs, withdrawing, etc. CN Product: The label may be a product designated as a child nutrition product. The CN number must be obtained from AMS prior to submitting the label into LSAS. Consultant: (see Agent) Earliest and Latest Submission Date: The label\u2019s submission date. Earliest and Latest Status Date: The date the status of the label was changed. Earliest and Latest Expiration Date: The date the label expired. Earliest and Latest Appeal Adjudication Date: The date the label was adjudicated. Egg Approval Number: Labels for use on egg products (frozen, dried, liquid), must be preapproved. A separate label approval number containing one letter and a three-digit number (e.g., M001) is assigned to each label that has been approved. The assigned USDA approval number must be printed within a rectangular box and needs to be no larger than the smallest printing on the label. Labels identifying imported egg products will contain a twoletter prefix, (e.g., CN001) and labels approved for identification of products for export only will have a oneletter code.

September 09, 2019 169 Appendix A: Glossary", "Label Submission and Approval System (LSAS) Industry User Guide

Establishment Number: An identification number assigned to an establishment. Establishment Type: Identifies an establishment as either domestic or foreign. Firm: The primary contact organization associated with a label application. The firm is usually, but not always, the same as the label application\u2019s establishment. HACCP Process Category: The category the product falls under based on the processing operations at establishment. Ingredient Name: An ingredient that is part of the product\u2019s formula. Name of Product: The field name as displayed on Form 7234-1 (block 5a), the Product Information screen, the Search screen, the Search Results screen, the Summary screen, and the downloaded PDF of the Summary. Number of Days Requested: For temporary approvals, the submitter provides the number of days he wants to use the existing labels. Number of Labels on Hand: For temporary approvals, the submitter must provide the number of labels to use in the temporary period. Processing Procedures: A description of the procedures or steps used to process the product. Profile: A profile represents a company or establishment. A company may have one or more facilities or establishments. LSAS allows companies to assign profiles for each facility or establishment. Resubmission: A label application that was submitted more than once. Specials Claims Type: A label may have allergen, nutritional, and other specific attributes requiring additional documentation. Total Available Labeling Space: The space available on the

label. Type of Product: Type of product can be meat, poultry, egg, or other. September 09, 2019  
170 Appendix A: Glossary", "INSTRUCTIONS FOR PREPARATION OF FSIS FORM 7234-1 Note: The following instructions should be typed unless otherwise noted. A. B. C. D. E. PREPARATION OF APPLICATION Application must be typed or it will be returned without evaluation. Submit two copies for each label application. TYPE OF APPROVAL REQUESTED Skelch: Selfexplanatory. (See9CFR317.4&381.132) Temporary and Extension of Temporary. Actual label or color litho take off to be used. FOREIGN LANGUAGE Labels printed in foreign languages must be accompanied by English language translation ASSEMBLY OF APPLICATION Application Form, Product Formula, Processing Procedures, Continuation Sheet if applicable, Label, and any Supporting Documentation Staple with one or as few staples as possible. (Do not use paper clips). MAIL COMPLETED APPLICATION TO: USDA, FSIS, OPPD, LPDD labeling Distribution Unit Stop Code 3786, Patriots Plaza III, 8-168 1400 Independence Avenue, SW Washington, DC 20250-3700 The following instructions relate to numbered items on form. 1. If using an Agent, provide the company name, address, and telephone number, otherwise leave blank. 2 & 3 Leave blank, for USDA use only. 4. Establishment No Foreign Country (if applicable)-Self Explanatory. 4a. 5a 5b Type of Product. Select one product type: Egg, Meat, Poultry, or Other (i.e. Exotic Species, Non-Amenable, Voluntary, etc.) Name of Product. Use common or descriptive product name, Le., "Frankfurter . Cereal Added" or "Meat Patties in Gravy. (Do not use trade brand names or coined names, such as "Joe's Corn Dogs" or "Joe's Sloppy Joes. j If coined names such as .. Corn Dogs~ are used, also show true product name, such as "Balter Wrapped Wiener." Provide HACCP process category for the product. See 9 CFR 417.2(b) (1), Example, Heat Treated -shelf stable, Not heat treated-shelf stable etc. Select one. 6a & b. Type of Approval Requested. If temporary approval or extension, insert number of days requested and number of labels on hand. If previous approval, attach copy of application and label. Include specific reason(s) why requesting a temporary or extension and include information required in 9 CFR 317.4(Q (1) or 381.132(Q (1) on the continuation sheet 7a. Be sure to include product name and block item. Area of Principal Display Panel (PDP). The PDP is the entire side of the package to which the label is affixed. See 9 CFR 317.2 (d) and 381.116(b). FSIS FORM 7234-1 (11/16/2011) 7b. 8. 9. 10. Total available labeling space in square inches for entire package. USDA-AMS Child Nutrition Program Logo. Indicate if the product includes a USDA-AMS Child Nutrition Program Logo. Leave Blank. For USDA-AMS use only. Special claims, guarantees, or foreign language. Indicate if there are any special claims, guarantees, or foreign language on the label. Check all that apply. If Other Claims is selected, indicate specific claim(s) in space provided. 11. Name and Address of Firm. Insert Firm's name and mailing address. Use 2 letter symbol for State. Show postal zip code. 12 & 13 Signature and Date of Applicant or Agent. To be signed and dated by the applicant or agent representing the official establishment or plant. 14. 15. 16. Leave blank for USDA use only. Conditions Applying to Use of Label or Device. (Any condition, modification or remarks applied to the application when approved are conditions governing use of the approved devices.) Product Formula. List the ingredients by percent or weight in order of their predominance. If product consists of several components, e.g., a frozen dinner, list each component separately and indicate the percentage or amount of each component in the product. If additional space is needed, check the box for continuation Sheet, and use the Continuation Sheet. Be sure to include the product name and number of the block item. Express all ingredients in the same units, i.e., do not list some in

pounds and others in ounces. Check whether weight or percent is used. It is preferred that percentages be used, and the total must equal 100 percent. If weights are used, show in pounds, kilograms or grams. (No gallons, pints, cups, teaspoons, etc.) The total must equal the weights of the individual units. (Example: Crust+ Cheese +Sauce+ Meat= Total new weight of unit.) DO NOT use fractions. Express as decimals carried to two places, Example: 1-1/4 lbs., show as 1.25 lbs. Example: 314 lbs., show as .75 lbs. Processing Procedures. Poultry Products provide complete processing procedures as required in 9 CFR 381.134. Meat Products, provide complete processing procedures as required. Note: Approval of the sketch does not convey approval of the processing procedures. If additional space is needed, check the box for "Continuation Sheet" and use the Continuation Sheet. Be sure to include the product name and number of the block item. Label Submission and Approval System (LSAS) Industry User Guide Appendix B: FSIS Form 7234 (Label Application) Preparation Instructions NOTE: Copy and mailing requirements not applicable for electronic submission. September 09, 2019 171 Appendix B: FSIS Form 7234", "Label Submission and Approval System (LSAS) Industry User Guide Appendix C: FSIS Form 8822-4 (Appeal) Preparation Instructions NOTE: Copy and mailing requirements not applicable for electronic submission. FSIS Form 8822-4 is used to request label reconsideration from USDA, FSIS, Labeling and Program Delivery Staff (LPDS) for label applications (FSIS Form 7234-1) which have been modified or rejected. A. PREPARATION OF APPLICATION Application must be typed, or it will be returned without evaluation. B. ASSEMBLY OF APPLICATION Attach two copies of the completed FSIS Form 8822-4 along with two copies of the rejected or previously modified approval FSIS Form 7234-1 for which you are appealing. Include the rejection letter if applicable. Staple with one or as few staples as possible. Do not use paper clips. C. MAIL COMPLETED APPLICATION TO: USDA, FSIS, OPPD, Labeling and Program Delivery Staff Labeling Distribution Unit -APPEAL Stop Code 3786, Patriots Plaza III, 8-168 1400 Independence Avenue, SW Washington, DC 20250-3700 Express Mail Only: USDA, FSIS, OPPD, Labeling and Program Delivery Staff Labeling Distribution Unit -APPEAL Patriots Plaza III, 8-168 355 E. Street, SW Washington, DC 20024-3221 FAX: 301-504-0873 or 301-504-0875 Telephone: 301-504-0883 (Distribution Unit) Instructions: Complete all sections of Page 1 on the FSIS Form 8822-4. COMPANY REASON(S) FOR REQUESTING LABEL RECONSIDERATION. Provide a reason(s) why the label should not have been modified or rejected. This can be a simple statement. If additional space is needed, check the box for "Continuation Sheet" and use the Continuation Sheet provided. Written arguments supporting the basis for the appeal must be enclosed with the appeal. In addition, all uncontested modifications to labeling must be made prior to the submission of an appeal. When prior approvals are mentioned in your argument, provide complete, legible copies of the prior approvals. If numerous prior approvals are involved, provide a listing of the approval numbers and a few legible copies of the prior approvals. REVIEWER'S REASON FOR DISAPPROVAL OR MODIFICATION. Include the label reviewer's reason(s) for the rejection and/or modification. If unsure, leave blank. September 09, 2019 172 Appendix C: FSIS Form 8822-4", "Label Submission and Approval System (LSAS) Industry User Guide Appendix D: LSAS Tips LSAS TIP 1 (updated) What is a temporary establishment? When should I utilize this function? If a submitter does not yet have an establishment number for an establishment he is associating to a label application, then LSAS can generate a temporary establishment number until the official number is assigned. NOTE: If you know the establishment's name or number, then you must utilize the "Add

Establishment from PHIS\button rather than using the temporary establishment function. This is to keep establishment data consistent in LSAS. LSAS TIP 2 \u2013 Label Image Resolution When attaching your Label Image to your submission, we recommend the resolution be set at 300 dpi when scanned and orientation set to portrait. LSAS TIP 3 \u2013 How to Print An Adjudicated Label with Annotations (Stamps, Modifications, etc.) Select all the documents that you want to include in the download. Be sure to check the \u201cInclude Annotations\u201d checkbox. After downloading, in the Adobe Reader window, from the Print menu under \u201cComments & Forms\u201d, select \u201cDocument and Markups\u201d. Then proceed to print LSAS TIP 4 (updated) \u2013 My application was returned to me. Where do I find the reason(s) it was returned? You will find the reason(s) for the returned submission by reviewing the Label Application Comments located at the bottom of the detailed Summary. Select your returned application from the Returned Pool. Select Manage Application, Select Summary from the Available Actions, and scroll to the bottom of the page to review the Label Application Comments entered by the technical reviewer. LSAS TIP 5 \u2013 How do I resubmit my returned application to LPDD? Select your returned application from the Returned Pool, Manage Application, and Select Edit from Available Actions. This function allows you to make corrections, additions, deletions, etc. You can navigate to the specific area of the application by using the Go To function in the upper right corner of the dashboard. Be sure to save your changes. Finally, using the Go To function, Select 7234 Summary to review and submit your application. When the application is resubmitted, it will appear in the LPDD pool as a resubmittal. LSAS TIP 6 (updated) \u2013 I received a Sketch Modified label. Where do I find the explanation of the modifications that were made? Reason(s) for the modifications can be located on the annotated label image, application form, and/or in the Comment field section of the Summary. LSAS TIP 7 \u2013 Appeal The \u201cAppeal\u201d function should only be used if an establishment disagrees with a specific modification or reason for rejection. For additional guidance see the instruction page for Form 8822-4. Selection of an appeal is not a means to \u201cresubmit\u201d a returned application, Example: reviewer request a legible copy of label. See Tip 5 posted in the Announcements. September 09, 2019 173 Appendix D: LSAS Tips", "Label Submission and Approval System (LSAS) Industry User Guide LSAS TIP 8 (updated) \u2013 Extraordinary Circumstances The selection of an \u201cExtraordinary Circumstances\u201d should only be chosen if the product has been retained ("tagged") by program personnel at official establishments or when there is some other unforeseeable impediment to movement of meat or poultry product, and a temporary label approval would remove the impediment. For complete policy guidance see the FSIS website:  
<http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatory-compliance/labeling/labelingprocedures/procedures-evaluating-labeling> LSAS TIP 9 \u2013 Formula Information When listing your ingredients for Step 6-Formula Information, DO NOT include any special characters, bullets, numbered listings, etc. Simply list the ingredient name. This ensures that ingredients can easily be added to the database. INCORRECT: # Cheddar cheese 109.Ham \*\*Parsley --Tomato Paste CORRECT: Cheddar cheese Ham Parsley Tomato Paste LSAS TIP 10 \u2013 Label Documentation To avoid unnecessary delays during label review: Do not upload images or documents that contain layers, comments, bookmarks, hidden text, or which are Password-Protected, i.e., FSIS Form 7234-1. Files that are created in Adobe Illustrator\u2014or similar imaging applications\u2014must be flattened before being uploaded

to LSAS. NOTE: Printer-ready labels are composed of multiple layers of information. In some cases, a layer consisting of a clear mask or \u201cvarnish\u201d overlays all underlying layers. It is important that this layer be disabled or turned off before uploading the image to LSAS.

LSAS TIP 11 -Egg Product Labels and Exotic Species To avoid unnecessary delays, labels for egg products and exotic species are NOT eligible for generic approval and they must be submitted to LPDS for review and approval. Therefore, please select \u201cno\u201d to the question: \u201cAre you requesting a voluntary review for a label that can be generically approved?\u201d

.....15", "4 United States Department of Agriculture Food Safety and Inspection Service veal slaughter sanitary dressing deficiencies What issues has FSIS identified concerning veal slaughter establishments? FSIS test results show that the percent positive for Shiga toxin-producing Escherichia coli (STEC) from trimmings produced from veal appears to be higher than that for trimmings produced from other cattle slaughter classes. FSIS identified common deficiencies: inadequate sanitary dressing, ineffective antimicrobial intervention implementation, and failure to use microbial data in decisionmaking. What are some examples of the sanitary dressing deficiencies FSIS observed repeatedly during onsite visits to veal slaughter establishments? Cutting through the weasand (esophagus) during sticking resulting in ingesta contaminating the carcass and head. Cutting through the hide and further processing without sanitizing knives, gloves, and equipment adequately to prevent carcass contamination.", "5 United States Department of Agriculture Food Safety and Inspection Service sanitary dressing deficiencies Cutting through the hide and into the carcass without sanitizing knives, resulting in carcass contamination. Hide flaps contaminating carcass. Bagged bung contacting hide and contaminating carcass.", "6 United States Department of Agriculture Food Safety and Inspection Service veal slaughter sanitary dressing deficiencies Exposed bung contaminating the carcass. Puncturing paunch and intestines during evisceration, resulting in carcass contamination. Ingesta from punctured paunch and intestines, resulting in carcass contamination.", "7 United States Department of Agriculture Food Safety and Inspection Service sanitary dressing deficiencies Eviscerating carcass with the hide on, resulting in carcass contamination. Cold skinning (removing the hide after the carcass has chilled down), resulting in carcass contamination. Contaminated carcass in cooler as a result of sanitary dressing deficiencies.", "8 United States Department of Agriculture Food Safety and Inspection Service veal slaughter sanitary dressing Contaminated packaged product in freezer as a result of sanitary dressing deficiencies. What are some examples of antimicrobial intervention implementation deficiencies FSIS observed repeatedly during onsite visits to veal slaughter establishments? Crosscontamination of heads from carcass intervention overspray.", "9 United States Department of Agriculture Food Safety and Inspection Service antimicrobial intervention deficiencies Intervention failing to achieve full carcass coverage, thus reducing the intervention\u2019s effectiveness. Intervention failing to achieve full product coverage, thus reducing the intervention\u2019s effectiveness. Intervention failing to achieve full product coverage, thus reducing the intervention\u2019s effectiveness.", "veal slaughter sanitary dressing best practices 10 United States Department of Agriculture Food Safety and Inspection Service veal slaughter sanitary dressing best practices What other issues did FSIS identify at veal slaughter establishments? FSIS observed that veal slaughter establishments were not properly evaluating testing results, including indicator organism results (e.g., generic E. coli, Aerobic Plant Count, or Enterobacteriaceae) on carcasses and STEC on beef manufacturing trimmings

and in ground veal to help determine how the results impact their slaughter operation. What are some examples of best practices concerning sanitary dressing? Misting hides in pens to reduce dust and dirt particles. Rodding the weasand to free the weasand from the trachea, making it easier to close the weasand.", "antimicrobial intervention deficiencies 11 United States Department of Agriculture Food Safety and Inspection Service sanitary dressing best practices Weasand clip to prevent leakage of rumen contents. Reflecting the hide away from the carcass during skinning to prevent contamination from the hide. Dual knife system for sterilizing knives.", "veal slaughter sanitary dressing best practices 12 United States Department of Agriculture Food Safety and Inspection Service veal slaughter sanitary dressing best practices Hide clips for preventing contamination from the hide. Tying and bagging bung to prevent spillage of fecal material. Preventing puncturing the paunch and intestines during evisceration.", "antimicrobial intervention deficiencies 13 United States Department of Agriculture Food Safety and Inspection Service sanitary dressing best practices How do veal slaughter establishments implement effective sanitary dressing procedures to prevent carcass contamination and the creation of insanitary conditions? Establishments should develop a comprehensive written sanitary dressing program. The program should include written procedures to prevent carcass contamination. The program should include verification activities that ensure employees are performing the procedures as written and the procedures effectively prevent contamination. Establishments should assess the effectiveness of their procedures using real-time data and assess the impact of microbial results on their slaughter operation. What are some examples of best practices concerning antimicrobial intervention implementation? Hind limbs are spread apart to allow intervention to achieve full carcass coverage. Applying intervention according to supporting documentation. All nozzles are operational, and critical operating parameters are met. Lactic acid dispenser with gauges for monitoring temperature and pressure that, depending on the establishment's supporting documentation, may be critical operating parameters.", "14 United States Department of Agriculture Food Safety and Inspection Service veal slaughter sanitary dressing best practices How do veal slaughter establishments implement antimicrobial interventions effectively? \u2022 Identify supporting documentation that closely matches selected intervention. \u2022 Identify critical operating parameters in the supporting documentation. Critical operating parameters are the specific conditions (such as contact time, pH, temperature, and concentration) of the intervention that must be met for the intervention to be effective. \u2022 Incorporate critical operating parameters into Hazard Analysis and Critical Control Point (HACCP) system. \u2022 Implement intervention so that it meets critical operating parameters. How do establishments properly assess microbial testing results? \u2022 Use test results to assess the effectiveness of their controls for preventing contamination. \u2022 Identify specific criteria for use when the slaughter process is determined to be out of control. \u2022 Verify that their slaughter controls are reducing STEC to a non-detectable level on an ongoing basis. \u2022 Review sanitary dressing procedures and intervention measures to investigate the cause when microbial test results indicate a loss of process control. \u2022 Perform increased microbial testing to demonstrate that the corrective actions taken in response to the loss of process control are effective. CDC reports an increase of 18% from 1997 to 2007 among children \u2022 The average number of hospital discharges per year related to food allergy diagnosis has increased significantly from 1998 to 2006 among children with approximately 9,500 hospital discharges yearly from 2004 to 2006 (CDC) \u2022 An estimated 29,000 episodes of anaphylaxis related to food occur in the United States each year, resulting in approximately 150 deaths (Atkins)

Chapter 1: Introduction and Background This document provides recommendations for identifying hazards when conducting a hazard analysis and for preventing and controlling hazards through hazard analysis and critical control point (HACCP) plans, Sanitation standard operating procedures (SOPs), or other prerequisite programs with respect to allergens and other ingredients of public health concern. The focus of the guidelines presented in this document is on meat and poultry products with an emphasis on FSIS-regulated establishments, state-regulated establishments, and operations where all or part of the premises meet the \u201cfood processing plant\u201d definition as defined in the Food Code. The guidelines provide information on proper procedures for processing, handling, storing, and labeling a product with an allergenic ingredient or ingredient of public health concern based on three basic principles: 1. Identify 2. Prevent and control 3. Declare Key components of the identify

principle include hazard analysis, inspection of incoming ingredients, cross-referencing product components, and separation of allergenic materials. The prevent and control principle focuses on recommendations for preventing cross-contact in processing areas, such as sanitation and cleaning of equipment and maintaining appropriate process flow. Finally, the declare principle emphasizes prevention of mislabeling during packing, labeling, and storage. These guidelines represent the best practice recommendations of FSIS, based on scientific and practical considerations. The recommendations are not requirements. By following these guidelines, establishments are likely to ensure that product labels declare all ingredients, as required in the regulations, and that products do not contain undeclared allergens or other undeclared ingredients. FSIS recommends that establishments consider incorporating the practices set out in this document in their HACCP plan or Sanitation SOPs or other prerequisite programs.

1.1 Why did FSIS develop this document? From 2008 through 2012, there has been a The \u201cBig Eight\u201d Allergens 1) Wheat 2) Crustacean shellfish (e.g. shrimp, crab, lobster) 3) Eggs 4) Fish 5) Peanuts 6) Milk 7) Tree nuts (e.g. almonds, pecans, walnuts) 8) Soybeans Recall Trends: FSIS-regulated Product Related to Undeclared Allergens \u2022 The number of recalls of FSIS-regulated product attributed to undeclared allergens and ingredients of public health concern has increased from 7 in 2008 to 29 in 2012 \u2022 The proportion of recalls attributed to undeclared allergens and ingredients of public health concern has also increased, from 13% in 2008 to 35% in 2012 4", "Food allergy: Adverse health effect arising from a specific immune response that occurs reproducibly on exposure to a given food (NIAID) Signs and symptoms of food allergy: According to the CDC, depending on the individual and allergy, the signs and symptoms can vary from mild to sudden and severe, including one or more of the following: \u2022 Hives \u2022 Tingling in the mouth \u2022 Swelling in the tongue and throat \u2022 Difficulty breathing \u2022 Abdominal cramps \u2022 Vomiting or diarrhea \u2022 Eczema or rash \u2022 Coughing or wheezing \u2022 Loss of consciousness \u2022 Dizziness Anaphylaxis: Severe, life-threatening, whole body allergic reaction that occurs seconds to minutes after exposure and can result in respiratory distress, shock, and death According to the NIAID, some food allergens cause allergic reactions primarily if eaten raw; however, most food allergens can still cause reactions even after they have been cooked or have undergone digestion in the stomach and intestines. Ingredients of public health concern: Ingredients to which consumers have reported adverse reactions Food allergens: Specific components of food or ingredients within food (typically proteins) that are recognized by allergen-specific immune cells and cause specific immunologic reactions, resulting in characteristic signs and symptoms (NIAID) sustained increase in the number of recalls of FSIS-regulated product that contained undeclared allergens. These recalls are preventable as many have been the result of ingredient changes, product changes, products in the wrong package, or products with misprinted labels. The consumption of meat and poultry products containing ingredients of public health concern, such as undeclared allergens, may result in adverse health outcomes for certain individuals. According to the National Institute of Allergy and Infectious Diseases (NIAID), the \u201cBig Eight\u201d allergens account for approximately 90 percent of all food allergy reactions. Situations involving the non-declaration of the \u201cBig Eight\u201d allergens may result in a Class I or Class II recall. (Refer to FSIS Directive 8080.1 for additional information on product recall.)

1.2 What is a food allergen? More than 170 foods have been reported to cause allergic reactions; however, eight of the most common allergenic foods account for 90 percent of all food allergic reactions

and are the sources from which many other ingredients are derived. Food allergies are an important public health problem that affect adults and children and are increasing in reported prevalence. There is currently no cure for severe allergic reactions. Therefore, it is necessary to provide guidance on avoiding specific foods, reviewing labels, and managing the relevant signs and symptoms of those that are affected. Establishments are required to declare all ingredients on the label. While the \u201cBig Eight\u201d allergens are the most common allergenic foods, people may have adverse reactions to other substances as well. Consumption of some ingredients, such as sulfur-based preservatives (sulfites), lactose, FD&C Yellow 5 (Tartrazine), gluten, and monosodium glutamate (MSG), may result in an adverse reaction in certain susceptible individuals, yet they are not considered allergens. It should also be noted, especially for establishments producing product for export, that countries outside of the U.S. may have concerns for other allergens that may need to be addressed. For example, Canada and the European Union recognize more than the \u201cBig Eight\u201d allergens.

5", "1.3 What are the undeclared allergen trends that FSIS has observed in industry? FSIS has recognized a notable increase in the number of recalls that have occurred because of undeclared allergens and ingredients of public health concern in product. FSIS has found that many of these recalls occurred because of a change in product formulation by the establishment or a change in a supplier\u2019s ingredient formulation that was not reflected on the labeling of the finished meat or poultry product. If an establishment recalls product because of an undeclared ingredient, an establishment likely has: 1) failed to address the chemical (allergen) food safety hazard in its hazard analysis, 2) failed to support the decisions made in the hazard analysis, 3) failed to reassess the hazard analysis, or 4) failed to effectively implement the controls to support the decisions made in the hazard analysis (see 9 CFR 417.2(a)(1), 417.5(a)(1), 417.4(a)(3), 417.3(b) respectively). In some cases, FSIS requested that establishments recall product in commerce because FSIS in-plant inspection personnel or Enforcement, Investigations, and Analysis Officers (EIAs) found undeclared allergen problems.

Establishments should take steps to identify such problems instead of relying on FSIS to find them. Establishment controls should be in place to address the presence of undeclared allergens and ingredients of public health concern. Establishments are required to declare ingredients on the label if they are included in the product formulation (9 CFR 317.2 and 381.118). Allergen-containing products must be handled, processed, formulated, and stored properly. If allergens are not declared, then the product is adulterated and misbranded. If adulterated and misbranded product has already been shipped into commerce, FSIS would request that it be recalled.

1.4 What is the Food Allergen Labeling and Consumer Protection Act (FALCPA)? The 2004 Food Allergen Labeling and Consumer Protection Act (FALCPA) requires that products under the jurisdiction of the Food and Drug Administration (FDA) that contain a major food allergen clearly identify the allergen on the label (Public Law 108-282, Title II). FSIS supports the voluntary addition of allergen statements (e.g. \u201ccontains\u201d statements) on meat and poultry product labels immediately following the ingredients statement as discussed in the FSIS Compliance Assistance: Allergens-Voluntary Labeling Statements. All ingredients used in the formulation of meat, poultry, or egg products must be declared by their common or usual name in the ingredients statement. Occasionally a substance may be used in a meat, poultry, or egg product whose use in that product, consistent with FDA\u2019s labeling definition, would be as an incidental additive or a processing aid (21 CFR 101.100(a)(3)). If an

establishment believes that a substance is a processing aid or incidental additive in a meat, poultry, or egg product, it should contact FSIS for a determination. FSIS makes these determinations on a case-by-case basis, as discussed in the FSIS Compliance Guide on the Determination of Processing Aids. What is causing undeclared allergen recalls? \u2022 New Ingredient \u2022 New Supplier \u2022 Misprinted Label \u2022 Product in Wrong Package \u2022 Product Reformulation \u2022 Ingredient Reformulation 6", "Food safety hazard: Any biological, chemical, or physical property that may cause a food to be unsafe for human consumption Chapter 2: Prevention and Control Measures for Undeclared Allergens For comprehensiveness, FSIS recommends control measures throughout an establishment\u2019s HACCP system to prevent the potential of undeclared allergens based on three basic principles: identify, prevent and control, and declare. Below are steps establishments should take that could be incorporated within the HACCP plan or Sanitation SOPs or other prerequisite program. As appendices to this document, there are several resources that can be used in conjunction with the identify, prevent and control, and declare concepts: \u2022 Page 14 depicts \u201cHow to Handle Labels of Incoming and Outgoing Products\u201d in a diagram detailing recommended procedures to maintain proper handling of labels. \u2022 Page 15 contains a process flow diagram that illustrates the targets for mitigation in a hypothetical flow diagram for fresh pork sausage. This mitigation targets are highlighted to correspond with the identify, prevent and control, and declare principles emphasized in this guidance. \u2022 Page 16 illustrates an allergen risk evaluation and labeling flow chart to assist with an establishment\u2019s evaluation of whether or not special labeling is needed. \u2022 Page 17 is the beginning of the specific \u201cEstablishment Checklists\u201d that are provided to assist establishments with questions to consider as they brainstorm the identification, prevention and control, and labeling of allergens. \u2022 Page 20 includes \u201cAllergen Scenarios and Possible Preventive Measures\u201d that are hypothetical scenarios along with preventive measures that could have been taken to illustrate the concepts from the guidelines. \u2022 Page 22 is the beginning of a resource entitled \u201cAllergenic Ingredients and Foods\u201d which was adapted from Food Allergy Research and Education (FARE) to help establishments identify \u201cBig Eight\u201d allergens. \u2022 Page 26 highlights the references and sources of information used throughout this document along with other resources for additional information.

2.1. Identify: Inspection of Incoming Ingredients, Cross-referencing Components, Separation A meticulous, comprehensive hazard analysis is crucial to identify and control allergens in an establishment. The hazard analysis serves as the foundation for a strong and successful HACCP plan. Therefore, it is important for the establishment to invest time and resources in the analysis, particularly in hazard identification. According to 9 CFR 417.2(a)(1), the establishment is required to identify all food safety hazards reasonably likely to occur through a hazard analysis. Doing so would include identifying any chemical hazards, such as allergens and ingredients of public health concern, as well as any biological and physical hazards that are reasonably likely to occur in the production process. The introduction of an allergen could occur anywhere during the production process. Therefore, an establishment should be sure to evaluate each step in its process from receiving to packaging and shipment. Allergens fall under the chemical hazards portion of the hazard identification. The introduction of ingredients into product must be taken into account during the hazard analysis 7", "FSIS has found that establishments have not been aware of the potential presence

of allergens within a new ingredient or formulation when changing suppliers or the formulation of an ingredient. It is essential that establishments routinely verify that the ingredient's label reflects its formulation. When a change in suppliers or formulation occurs, establishments should be on high alert for the presence of allergens in the new ingredient or product. It is the establishment's responsibility to routinely check the ingredient's formulation. A hazard analysis is not only used to assess the food safety hazards reasonably likely to occur in the production process but is also used to identify the measures through Critical Control Points (CCPs) that the establishment can apply to control those hazards. The hazard analysis must consider food safety hazards that can occur before, during, and after entry into the establishment. Establishments should be especially thorough during the hazard identification phase of their hazard analysis to identify food safety hazards and ultimately to mitigate the possibility of preventable recalls because of undeclared allergens and ingredients of public health concern. In these guidelines, FSIS has provided measures for controlling the presence of undeclared allergens in product that may be included in an establishment's HACCP system. Measures may also be included within an establishment's Sanitation SOPs or other prerequisite program that sufficiently and effectively prevent the presence of undeclared allergens in product. As a result of the identification of chemical hazards in the hazard analysis, an establishment should have a list of allergens and other ingredients of public health concern that are used in production. According to the National Advisory Committee on Microbiological Criteria for Foods (NACMCF), establishments should evaluate each of these identified hazards based on severity as well as likelihood of occurrence. This evaluation could be based upon historical data, scientific literature, or establishment records. Once the hazard evaluation is completed, establishment personnel should work to develop approaches to control those hazards. As part of food safety and hazard control under federal regulation, every establishment is required to have a written HACCP plan based on its hazard analysis (9 CFR 417.2(b)(1)). The HACCP plan is required to include the food safety hazards reasonably likely to occur in the production process. The establishment is required to have a flow chart describing the steps of each control process and product flow in the establishment (9 CFR 417.2(a)(2)). Every establishment must validate the HACCP plan's adequacy in controlling the food safety hazards, such as undeclared allergens, identified during the hazard analysis. What are some straightforward, practical steps I can take to identify allergens in my establishment?

\u2022 Review a list of all ingredients and products that you use to determine whether they are or contain allergens \u2022 Using an establishment schematic, do a walkthrough noting paths of allergenic ingredients and products and areas of concern where crosscontact may occur \u2022 Keep a list of ingredients used in product formulations and label records at the receiving area to compare against incoming ingredients \u2022 Ensure that all incoming ingredients containing allergenic material are clearly labeled and identified \u2022 Use color coding for allergen-containing ingredients and products \u2022 Store ingredients containing allergenic materials in separate, designated areas that are clearly identified and marked \u2022 Become familiar with letters of guarantee from suppliers \u2022 Maintain open communication of expectations with suppliers and inquire about suppliers' allergen control programs

8", "What is a letter of guarantee (LOG)? A LOG is a document that provides details for components that are used in the areas of food processing, handling, and storage. Generally, a LOG contains:

- \u2022 Supplier name and address
- \u2022 Brand name
- \u2022 Statement that

the material is safe and effective under intended conditions of use and will not adulterate the food product \u2022 Signature of an official of the supplier The LOG may be attached to an invoice or may be a continuing LOG that does not accompany each shipment. and verify that the plan is being effectively implemented to reduce the potential for the presence of undeclared allergens in the product. To fully address all allergens and ingredients of public health concern in the final product, an establishment should first assess ingredients present in the incoming meat or poultry and non-meat or non-poultry components. The establishment should seek out information about the allergens and ingredients of public health concern used by its suppliers. In addition, it should seek information on its suppliers\u2019 production practices, such as whether they employ practices to prevent the cross-utilization of equipment or cross-contact of product. This information may come in the form of a Letter of Guarantee (LOG) that should not to be confused with a Certificate of Analysis (COA). A COA typically includes test results associated with a specific lot, while a LOG may be provided by the supplier to describe the ingredients used in the production of products. Based on the component and complexity of the supplier\u2019s process, the content of the LOG can vary significantly, from a general statement, which is common, to a more detailed description of the supplier\u2019s process (e.g., details including ingredient components, processing aids, rework, processing steps, environmental conditions, or product carry over). In either situation, the LOG should accomplish the same function and be detailed enough to support the decisions made in the hazard analysis. An establishment should review and update the LOGs regularly to ensure that the decisions made in the hazard analysis are supported and to ensure that any formulation changes made by its suppliers are detected prior to incorporating the associated ingredient into the production process. Generally, an annual LOG will not be sufficient to support decisions made in the hazard analysis. An establishment that fails to routinely review and verify the components and ingredients it receives may overlook the presence of an allergen. The result may be the inclusion of a component that is not declared in a product resulting in adulteration and misbranding, which could ultimately lead to a product recall. FSIS recommends that an establishment maintain an approved supplier list along with ingredient information from each supplier. The establishment should use the list when receiving incoming ingredients to verify proper identification of each lot of ingredients. For accuracy, an establishment should also cross-reference the sketch label approval, if applicable, to the actual label being used and the formulation data. It is imperative that the label approval, the actual label, and formulation all match for proper ingredient identification. If there is a discrepancy between the label and the formulation, Every establishment must reassess the adequacy of its HACCP plan at least annually and whenever any changes occur that could affect the hazard analysis or alter the HACCP plan (9 CFR 417.4(a)(3)(i)). These changes may include: \u2022 Raw materials or source of raw materials \u2022 Product formulation \u2022 Slaughter or processing methods or systems \u2022 Production volume \u2022 Personnel \u2022 Packaging \u2022 Finishing product distribution systems \u2022 The intended use by consumers of the finished product \u2022 Outbreaks or illnesses associated with this type of product The reassessment and the reasons for any changes to the HACCP plan must be documented. Reasons that the HACCP plan is not changed must also be documented, unless it is an annual reassessment, and no changes are needed (9 CFR 417.4(a)(3)(ii)). 9", "Cross-contact: Inadvertent transfer of allergens to a food product from other food products, food contact surfaces, equipment, utensils, etc. if

ingredients or allergen-containing products are not handled properly establishment should separate the product and ingredients in question and hold them in a secure place, so that they are not used until the ingredients can be properly identified for use in specific products. FSIS labeling guidance, including the Food Standards and Labeling Policy Book, is available on the FSIS website. An establishment can prevent the presence of undeclared allergens by ensuring that appropriate mechanisms for labeling all ingredients are in place. A comprehensive chart, on page 15, details recommended procedures to maintain proper handling of labels on both incoming and outgoing product. As exhibited, this process should be conducted on an ongoing basis.

**2.2 Prevent and Control: Equipment, Sanitation, and Processing**

It is especially critical for establishments to address cleaning of equipment, utensils, and food contact surfaces (FCS) when producing both allergenic and non-allergenic product, to prevent cross-contact and misbranding. Personnel should be trained on the cleaning procedures the establishment employs to control food allergens and should be aware of which products contain allergenic ingredients. Establishments should track work-in-progress product with at least the product name, lot code, and allergenic ingredients or ingredients of public health concern to minimize potential cross-contact during processing. Equipment and utensils used for the preparation, processing, or other handling of all product, including allergenic product, in the establishment need to be suitable for the purpose intended and be of such material and construction that will facilitate thorough cleaning and ensure cleanliness in the preparation and handling of products. Cleaning of equipment, utensils, and FCS areas should be conducted after an allergenic product has had contact with a utensil, surface, or piece of equipment, and before the equipment, utensils, and FCS areas are used for an allergen-free product. It is important that equipment used to handle allergenic product be sufficiently sanitized before handling non-allergenic product. The type of product an establishment is producing, the food contact surfaces being used, and the allergens present in the product all should be considered when designing a cleaning program. A review by Jackson et al. presents cleaning, control, and validation strategies to prevent cross-contact with allergens. They note that, generally speaking, food proteins, which would include allergenic proteins, are some of the most difficult to remove from surfaces. Planning plays a key role when handling and processing both allergenic and non-allergenic product. The most effective and appropriate protocol for handling and processing both allergenic and non-allergenic What are some straightforward, practical steps I can take to prevent cross-contact in processing areas within my establishment? \u2022 Color coding of ingredient packages, supplies, uniforms, and utensils used for products containing allergens throughout processing to facilitate simple identification \u2022 Documenting cleaning procedures with checklists including procedures for spill clean-up \u2022 Employing a method for the verification and validation of cleaning \u2022 Maintaining documented process flow along with mapping the route of allergenic product through the establishment \u2022 Employing a method for tracking of lot codes through production \u2022 Carefully evaluating rework and work-in-progress \u2022 Dedicating equipment or, if not feasible, separate allergenic products by time, space, etc. 10", "FSIS does not recognize a threshold for any allergenic ingredient. Thus, all allergenic ingredients need to be declared on the product label. Allergen test kits as well as laboratory testing using reference laboratories targeted at allergens of interest are available. AOAC International maintains a listing of Performance Tested Methods which includes food allergen kits. This type of allergen testing program may be considered to

verify and document sanitation effectiveness in an establishment. Note that an allergen testing program would be a supplement to documenting cleaning procedures and a visual cleaning assessment. products is to handle and process non-allergenic products before handling and processing allergenic products to reduce the possibility of cross-contact and misbranding. This approach eliminates the need to hold utensils and equipment for proper cleaning before handling and processing allergenic product. FSIS recommends conspicuously and distinctly marking all equipment and utensils used for handling allergenic products. Cleaning and sanitizing equipment, FCS, and utensils is effective at not only removing soil and microorganisms but also food allergen residues. Additionally, FSIS recommends that establishments avoid using the same cooking medium (e.g., oil or water) when processing both allergenic and non-allergenic products. If an establishment chooses to utilize the same cooking medium, it is important that non-allergenic product does not become adulterated with the allergenic product in the cooking medium. Adulteration can be prevented by processing the non-allergenic product before the allergenic product.

**2.3 Declare: Packaging, Labeling, Storage**

Properly declaring allergens in product is just as important as properly identifying incoming ingredients and handling and processing allergenic product. Once an establishment has identified the potential allergens among the ingredients used and has handled and processed products according to its HACCP system, it is the establishment's responsibility to ensure that the product is properly packaged, labeled, and stored. An establishment should set procedures for personnel to easily distinguish allergenic product from non-allergenic product. Procedures should be in place to ensure that the label being applied to a given product within a production lot is correct and matches the label on other packaged units of product within the lot. These procedures should include the accurate identification of all potential allergens. If the product is incorrectly or insufficiently identified, it can lead to both adulteration and misbranding.

What are some straightforward, practical steps I can take to prevent mislabeling during packing, labeling, and storage of final product?

- \u2022 Systems and checklists in place for the labeling of final product
- \u2022 Conduct simulations with inaccurate product labels to test systems, checklists, and procedures
- \u2022 Color coding of products containing allergenic ingredients
- \u2022 Procedures in place for labeling discrepancies to ensure product disposition is evaluated
- \u2022 Verification of the accuracy of product labels
- \u2022 Methods of tracking lot codes through production, storage, and shipping
- \u2022 Storage of products containing allergenic materials in areas that are clearly identified and marked

**11"|"Question:** If an establishment produces a product that incorporates a non-meat or non-poultry ingredient that includes flour (an ingredient derived from wheat) and also produces a product that does not contain wheat, is the establishment required to note on the non-allergenic product's final label that the product may contain wheat or was manufactured in a plant with wheat to prevent false or misbranding information to consumers?

**Answer:** No, the presence of wheat in the establishment does not require a may contain statement on products formulated without wheat. Only in limited situations does FSIS allow the use of factual labeling statements about a product's manufacturing environment (e.g. Produced in an establishment that uses wheat). Statements of this type may only be used where good manufacturing practices cannot reasonably eliminate the unintended presence of ingredients of public health concern. In this case, the HACCP plan, Sanitation SOP, or other prerequisite program should be implemented by the establishment to control this

issue. Note: See the FSIS Compliance Assistance: Allergens-Voluntary Labeling Statements for additional information on the use of voluntary allergen statements of this type. Question: How should an establishment label its product when an incoming seasoning packet contains a \u201cmay contain\u201d statement on its labeling? Answer: All the ingredients in a \u201cmay contain\u201d or \u201cproduced in a facility\u201d statement of a purchased ingredient need not be listed on the final label if the official establishment: 1) Contacts the supplier and confirms in writing that the statement is a cautionary statement, and no such ingredient is in the product; and 2) Includes a written statement in its hazard analysis documentation to support why the \u201cmay contain\u201d or \u201cproduced in a facility\u201d statement is not carried forward to the finished meat or poultry product label. Additionally, the storage of the allergenic and non-allergenic products needs to be easily identifiable through product separation. An establishment should ensure that cross-contact of products does not occur when products are placed in freezers, refrigeration units, or dry warehouses. It should also take care when storing ingredients in dry warehouses or formulation rooms. An establishment should ensure that all ingredients in storage areas are properly identified to prevent employees from selecting the wrong ingredient during formulation. It is important that an establishment verify the accuracy of the final label to ensure that it includes all allergenic and non-allergenic ingredients in the product. An establishment should check the accuracy of labels in relation to the product being packaged. It may also include this procedure within its HACCP plan or other prerequisite program. The product in the package must precisely match the product described by the label on the package. Additionally, 9 CFR 317.2(b) and 9 CFR 381.116(a) require that the ingredients statement on the label be prominently placed with such conspicuously and in such terms as to render it likely to be read and understood by the ordinary individual under customary conditions of purchase and use. The ingredients statement must also identify the common or usual names of the ingredients arranged in descending order of predominance. A complete and accurate ingredients statement is essential with the presence of an allergen. If a discrepancy is found between the packaged product and the label, or if a product has been mislabeled, it is critical that the product be separated from product entering commerce and held. The occurrence should be immediately reported to the establishment management on duty.

"Chapter 3: Allergen Training Commitment All staff that handle and order ingredients, supplies, and equipment, as well as those who are responsible for handling ingredients and products from receiving through shipping, should be aware of the dangers of allergens. Each establishment employee needs to understand his or her food safety role in this process. An establishment should maintain written procedures to identify, prevent and control, and declare allergens and make those procedures readily available to staff. Staff should review the procedures frequently, especially when changes occur. Management should communicate the importance of allergen control and the establishment\u2019s allergen control program to all employees. The success of any system depends on education and training of management and employees in the importance of their role in producing safe foods.

Key Training Areas

\u2022 Avoiding cross-contact

\u2022 Flow of allergenic ingredients and products

\u2022 Allergen control policies

\u2022 Hygiene procedures including handwashing and uniform requirements

\u2022 Waste control

\u2022 Rework and work-in-progress procedures

\u2022 Cleaning procedures and documentation including spill clean-up

\u2022 Dedicated supplies and equipment

\u2022 Storage of ingredients and final products

\u2022 Labeling procedures

\u2022 Scheduling of production \u2022 Management notification for discrepancies and other allergen and labeling issues \u2022 Product formulations \u2022 Letters of guarantee

13", "Appendix 1: How to Handle Labels of Incoming and Outgoing Products Step 1 Inspect every lot of incoming ingredients and letters of guarantee at receiving, including product codes; Compare each lot against formulation and final labels Step 2 Review HACCP system for correct identification and evaluation of potential allergenic ingredients Step 3 Inspect each lot of ingredients and ensure all allergenic ingredients are identified in product\u2019s final label Step 4 Confirm accurate and available formulation data for each lot Step 5 Verify that the facility has a label approval for each product Step 6 Cross-reference the label approval to the actual label being used and formulation data for accuracy Step 7 Ensure the list of ingredients includes sub-ingredients on incoming and outgoing packaged product in processing lot Step 8 Ensure that the correct label is being applied to the correct product 14", "Appendix 2: Process Flow Diagram with Mitigation Targets Receiving Packaging Materials Receiving NonMeat Ingredients Storage Packaging Materials Storage Non-Meat Ingredients Preparing Non-Meat Ingredients Grind Blend Process Meat Storage Meat Receiving Meat Sausage Stuffer Packaging\ Labeling Rework Finished Product\ Storage (cold) Shipping Process Flow Diagram Process Category: Raw Product, Ground Product: Fresh Pork Sausage Identify Prevent and Control Declare Mitigation Targets 15", "Appendix 3: Allergen Risk Evaluation and Labeling Yes No No Yes Yes No Is the product manufactured from materials that contain allergens? If allergens are contained in the product, you should declare all allergens contained in the product on the label. Is the product manufactured on a production line or with equipment that comes in direct contact with allergenic substances? If no allergens are present in the product, no special labeling is needed. Implement all necessary measures to eliminate the risk for allergens on the production line and equipment! HACCP and good manufacturing principles should be used. If it can be documented that no allergen residue is in the product, no special labeling is needed. If it cannot be documented that no allergen residue is in the product, special labeling should be applied. In some cases, \u201cmay contain\u201d labeling may be applied. Be specific, such as \u201cmay contain peanuts.\u201d Can it be documented through cleaning controls, test results, or other means that no allergens are present on the production line and equipment or in the product? 16", "Appendix 4: Establishment Checklist Identify: Hazard Analysis, Inspection of Incoming Ingredients, Cross-referencing Components, and Separation Questions Yes No Comment Do we use non-meat or nonpoultry ingredients from a supplier in our product? Have we created a listing of the non-meat or non-poultry ingredients that we use from a supplier in our product? Do suppliers of ingredients have a documented allergen control program? Do our non-meat or non-poultry ingredients contain allergens or other ingredients of public health concern? Are ingredient specifications reviewed for formula changes? Is there a system in place to verify that purchased ingredients are correct when received? Are we addressing the accuracy of incoming ingredient labels? Are ingredients labeled if they contain an allergen? Are the product codes of purchased ingredients monitored for changes?

17", "Prevent and Control: Equipment, Sanitation, and Processing Questions Yes No Comment Do we have preventive measures in place in our HACCP plan or other prerequisite program that prevent the presence of undeclared allergens? If so, what measures are applied? Are ingredients stored and transported through the establishment in a manner that prevents cross-contact? Is the labeling and identification of allergenic ingredients maintained throughout

establishment processing (from receiving to shipment)? Is it possible to process products with allergens with dedicated supplies and equipment? If not, are allergenic products separated to prevent cross-contact? Is rework that contains allergenic ingredients only used with \u201clike\u201d items? Does our establishment have standardized procedures for sanitation for food allergens? Does our establishment have an established procedure for verification of the sanitation effectiveness for food allergens? 18", "Declare: Packaging, Labeling, and Storage Overall Questions Yes No Comment Are we addressing the accuracy of outgoing final packaged product? Does the finished product label, including sub-ingredients, match both the final label and formulation data on the non-meat or non-poultry ingredient label? Is there a system in place for traceback of non-meat and nonpoultry ingredients in the event of a concern, investigation, or recall? Do we ensure that employees responsible for labeling are aware if there are formulation changes? Questions Yes No Comment Have we trained our employees on how to properly inspect, process, store, and label allergenic product? Do employees have an understanding of the establishment\u2019s allergen control program? Are our control procedures for allergens being applied appropriately and verified of their effectiveness? 19", "Appendix 5: Allergen Scenarios and Possible Preventive Measures NOTE: An establishment is required to notify the district office within 24 hours of learning or determining that it has shipped or received in commerce adulterated or misbranded product (9 CFR 418.2). Scenario 1: Establishment A notified in-plant inspection personnel of a problem that it has discovered with a particular meat snack stick that it produced on five separate days in the last two weeks. The establishment\u2019s supplier changed its seasoning blend to include eggs; however, the snack stick label was not updated to include the presence of this allergen. IDENTIFY: The establishment should communicate with suppliers of ingredients to ensure they advise them of any changes in product formulation and allergens in the final product. IDENTIFY: The establishment should routinely check an ingredient\u2019s formulation, in this case, the seasoning used in the snack sticks. One possible solution is to keep product formulation and label records at receiving to compare against incoming ingredients. Additionally, establishment management should maintain active and open communication with suppliers and become familiar with letters of guarantee, packaging of ingredients, and ingredient product codes. DECLARE: The establishment could verify the ingredients within each product during the packaging and labeling of the snack sticks. Establishments should verify the accuracy of all labels on products and ensure that they appropriately reflect the ingredients used in the formulation. Not identifying the presence of an allergen or ingredient of public health concern means that the label is false and misleading, and the product is misbranded and adulterated. Verification of the product labels should be carried out and include a comparison of the formulation and ingredients contained in non-meat products. Scenario 2: Establishment B produced multiple products including two chicken entrees: one containing shrimp, and one containing vegetables but no shrimp. On two days, the establishment packaged and shipped the chicken and shrimp entree in the chicken and vegetables package. The problem was discovered by two consumers who purchased the entree and reported the wrong packaging to FSIS. DECLARE: Properly declaring allergens using the appropriate package is just as important as identifying ingredients and processing product. The establishment should consider using color-coding of products containing allergenic ingredients and should have a mechanism for verification of product labels, such as checklists at the point of packaging and labeling. Scenario

3: As a result of rising costs for a teriyaki sauce mix used in a stir fry meal produced by Establishment C, establishment management searched for a less expensive supplier. The sauce produced by the current supplier contained wheat and soy, which were properly declared on the meal label. A new supplier was found that could supply teriyaki sauce at a much lower price, and the establishment began using the product. After an investigation of four consumer complaints, in-plant inspection personnel discovered that the new teriyaki sauce contained milk and almonds, which were not declared on the meal label. IDENTIFY: In instances when establishments are changing suppliers, it is essential to communicate about expectations regarding ingredients and allergens. Prior to the change, the establishment should thoroughly review the ingredients contained in non-meat products, such as mixes or sauces. Again, at receipt at the establishment, the establishment should cross-check the ingredients used by the supplier against formulation and label records before accepting the ingredient at the establishment.

Scenario 4: Store D conducted testing of a pizza product produced by Establishment D. The testing revealed a peanut-containing ingredient that was not declared on the label, and Store D reported the 20", "presence of the ingredient to Establishment D. An FSIS Enforcement, Investigations, and Analysis Officer (EIAO) was dispatched to the establishment to investigate. He discovered that on the day of production, a peanut-containing product was run prior to the pizza on some of the same equipment, and that the establishment routinely uses the same utensils throughout the production day.

PREVENT AND CONTROL: Cleaning procedures need to be in place at establishments that produce both allergenic and non-allergenic products to prevent cross-contact and misbranding. Dedicated equipment and supplies should be considered, although separation by time can also be carried out effectively. In this instance, maintaining a documented process flow may have suggested a better production schedule to minimize cross-contact.

21", "Appendix 6: Allergenic Ingredients and Foods

Food Allergy Research and Education is a source of information regarding food allergies. One of the organization\u2019s resources for consumers lists allergenic ingredients and foods that may contain allergenic ingredients. The list of ingredients and foods below can be used to help identify \u201cBig Eight\u201d allergens.

1. Wheat Consumers allergic to wheat products are advised to avoid foods that may contain these ingredients. If meat, poultry, or egg products contain any of these, they likely contain wheat. bread crumbs Farina sprouted wheat wheat gluten bulgur flour\* triticale wheat grass cereal extract hydrolyzed wheat protein vital wheat gluten wheat malt club wheat Kamut wheat wheat protein isolate couscous matzoh\matzo, matzah\matza wheat bran wheat sprouts cracker meal Pasta wheat bran hydrolysate wheat starch durum Seitan wheat durum whole wheat berries einkorn semolina wheat germ emmer Spelt wheat germ oil \* all purpose, bread, cake, durum, enriched, graham, high gluten, high protein, instant, pastry, self-rising, soft wheat, steel ground, stone ground, whole wheat flour

Additionally, wheat is sometimes found in the following foods: baking powders (particularly imported) glucose syrup starch Worcestershire sauce bouillon soy sauce surimi

2. Crustacean Shellfish Consumers allergic to crustacean shellfish are advised to avoid foods that may contain these ingredients. If meat, poultry, or egg products have these ingredients, they contain a \u201cBig Eight\u201d allergen barnacle crawfish lobster shrimp crab Krill prawns

Additionally, crustacean shellfish are sometimes found in the following foods: bouillabaisse fish stock imitation fish\shellfish surimi cuttlefish ink glucosamine seafood flavoring

3. Eggs Consumers allergic to eggs are advised to avoid foods that may contain these ingredients. If meat or

poultry products contain any of these, they likely contain eggs. 22", "albumin\albumen egg white lysozyme ovalbumin dried egg egg yolk mayonnaise powdered eggs egg solids eggnog meringue surimi Additionally, eggs are sometimes found in the following foods: baked goods lecithin marzipan nougat egg substitutes macaroni marshmallows pasta 4. Fish It is generally recommended that consumers allergic to fish should avoid all fish. The most common kinds of fish that individuals are allergic to are salmon, tuna, and halibut. Additionally, fish is sometimes found in the following foods: Asian foods bouillabaisse meatloaf Worcestershire sauce barbecue sauce imitation fish\shellfish salad dressing 5. Peanuts Consumers allergic to peanuts are advised to avoid foods that may contain these ingredients. If meat, poultry, or egg products contain any of these, they likely contain peanuts. artificial nuts ground nuts nut meat peanut flour beer nuts mixed nuts nut pieces peanut protein hydrolysate goobers monkey nuts peanut butter Additionally, peanuts are sometimes found in the following foods: African, Asian, Latin American foods Chili marzipan baked goods egg rolls mole sauce candy enchilada sauce nougat The FDA exempts highly refined peanut oil from being labeled as an allergen. 6. Milk Consumers allergic to milk are advised to avoid foods that may contain these ingredients. If meat, poultry, or egg products contain any of these, they likely contain milk. butter caseinates half-and-half recaldent butter fat cheese lactalbumin rennet casein butter oil cottage cheese lactoferrin sour cream butter acid cream lactose sour milk 23", "butter ester curds lactulose tagatose buttermilk custard milk\* whey casein diacetyl milk protein hydrosylate whey protein hydrosylate casein hydrolysate ghee pudding yogurt \* milk in all forms (including condensed, derivative, dry, evaporated, goat\u2019s milk and milk from other animals, low fat, malted, milkfat, nonfat, powder, protein, skimmed, solids, whole) Additionally, milk is sometimes found in the following foods: artificial butter flavor chocolate margarine sausages baked goods hot dogs nisin bouillon lactic acid starter culture and other bacterial cultures nondairy products caramel candies luncheon meat nougat 7. Tree Nuts Consumers allergic to tree nuts are advised to avoid foods that may contain these ingredients. If meat, poultry, or egg products contain any of these, they likely contain a \u201cBig Eight\u201d allergen. almond coconut Nangai nut pili nut artificial nuts filbert\hazelnut natural nut extract pine nut beechnut gianduja nut butters pistachio Brazil nut ginkgo nut nut meal praline butternut hickory nut nut paste shea nut cashew litchi\lichee\lychee nut nut pieces walnut chestnut macadamia nut pecan chinquapin marzipan\almond paste pesto Additionally, tree nuts are sometimes found in the following foods: alcoholic extracts black walnut hull extract nut distillates walnut hull extract Asian foods natural nut extract nut oils 8. Soybeans Consumers allergic to soybeans are advised to avoid foods that may contain these ingredients. If meat, poultry, or egg products contain any of these, they likely contain soybeans. edamame soy fiber soy sprouts tamari miso soy flour soy yogurt tempeh natto soy grits soya textured vegetable protein shoyu soy ice cream soybean tofu soy albumin soy milk soy protein 24", "soy cheese soy nuts soy sauce \* FDA exempts highly refined soybean oil from being labeled as an allergen. However cold-pressed soybean oil, which is less commonly used, is not exempt from allergen labeling as it likely contains more residual protein. Additionally, soybeans are sometimes found in the following foods: Asian foods vegetable broth vegetable starch soy lecithin\* vegetable gum Worcestershire sauce \* With the exception of a few specific products, FDA does not exempt soy lecithin from allergen labeling as it generally contains residual protein. The use of soy lecithin in non-stick sprays and coatings (i.e. releasing agents) has led to recalls of FSIS-regulated product when the soy was not

properly declared. 25", "Appendix 7: References and Resources Atkins D, Bock SA. Fatal Anaphylaxis to Foods: Epidemiology, Recognition, and Prevention. 26"]}, {"file\_name": "FSIS\_GD\_2015\_0022", "title": "Compliance Guideline for Validating Cooking Instructions for Mechanically Tenderized Beef Products (2015)", "num": "FSIS-GD-2015-

0022","id":"17247667856af3256c771bd8cf5f5ec2d847bdea677df887985a73968495570","corpus":"fsis\_guidelines","source\_page\_url":"https:\V\www.fsis.usda.gov\policy\fsis-guidelines","url":"https:\V\www.fsis.usda.gov\sites\default\files\import\Comp\_Guide\_MTB.pdf","type":"pdf","n\_pages":31,"word\_count":10508,"text\_by\_page":["This guidance document is designed to help establishments that manufacture mechanically tenderized beef products to comply with the requirements in 9 CFR 317.2(e)(3)(iii) by: \u2022 Identifying the minimum components of validated cooking instructions; \u2022 Identifying the two elements to validating cooking instructions: o Scientific and technical support (design) and o In-plant validation data (execution) To help establishments meet the first element of validation, this document contains attachments establishments can use as scientific support for cooking instructions. 2012 FSIS Compliance Guideline for Validating Cooking Instructions for Mechanically Tenderized Beef Products 2015 i","Preface What is the purpose of this Compliance Guideline? The purpose of this guideline is to help establishments ensure that their labels on raw or partially cooked needle- or blade-tenderized beef products destined for household consumers, hotels, restaurants, or similar institutions contain validated cooking instructions that comply with the requirements in 9 CFR 317.2(e)(3)(iii). Note that these requirements are not in effect until May 17, 2016. In addition, FSIS will delay enforcing the labeling requirements for beef products with added solutions until the same date. Specifically, the guideline articulates: \u2022 The minimum components validated cooking instructions must contain; \u2022 The two elements to validating cooking instructions: o Scientific and technical support (design) and o In-plant validation data (execution) This document contains attachments that establishments can use as scientific support to meet the first element of validation. This document provides guidance to assist establishments in meeting FSIS regulations. Guidance represents best practice recommendations by FSIS based on the best scientific and practical considerations. It does not represent requirements that must be met. Establishments may choose to adopt different procedures than those outlined in this Guideline, but they would need to support why those procedures are effective. It is important to note that this Guideline represents FSIS's current thinking on this topic. Who is this Compliance Guideline designed for? This guideline is designed for all official FSIS regulated establishments that produce raw or partially cooked mechanically tenderized beef products destined for household consumers, hotels, restaurants, or similar institutions. Such products include raw or partially cooked needle or blade tenderized beef products, including mechanically tenderized beef products that have also been injected with marinade or solution. This guideline is not intended for establishments that produce mechanically tenderized product that will be fully cooked at an official establishment. Is this version of the guideline final? Yes, this version of the guideline, dated May, 2015 is final and replaces the previous version dated June, 2013. Guidelines will be continually updated to reflect the most current information available to FSIS and stakeholders, although comments will no longer be accepted through regulations.gov on this guideline. ii","What changes have been made to the guideline since the last version? The following changes have been made to the June, 2013 version of the guideline in response to public comments: \u2022 Based on findings from recent research shared in the comments, a recommendation to include the following statements as part of the validated cooking instructions was added: o \u201cFully thaw product before cooking,\u201d and o For mechanically tenderized steaks, \u201cTurn product over at least twice during cooking\u201d.

\u2022 Clarified that not all of the time and temperature combinations FSIS Guidance on Safe Cooking of Non-Intact Meat Chops, Roasts, and Steaks are practical for consumers to follow. Specifically, the rest times associated with the temperatures less than 145\u00b0F (e.g., 144\u00b0F for 4 minutes, 143\u00b0F for 5 minutes, etc.) are not practical for consumers to maintain. \u2022 Portion size was addressed as a factor to consider when designing a validation study. \u2022 Based on findings from recent research shared in the comments, additional scientific support for cooking instructions was included in Attachment 1. In addition, outbreak data was revised to reflect outbreaks from mechanically tenderized beef products that occurred since 2000. This change was made to be consistent with the data reported in the Federal Register Notice. What if I still have questions after I read this guideline? If the desired information cannot be found within the Compliance Guideline, FSIS recommends that users search the publicly posted Questions & Answers (Q&As) in the AskFSIS database or submit questions through AskFSIS. Documenting these questions helps FSIS improve and refine present and future versions of the Compliance Guideline and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter FSIS Compliance Guideline for Validating Cooking Instructions for Mechanically Tenderized Beef Products Question Field: Enter question with as much detail as possible. Product Field: Select General Inspection Policy from the drop-down menu. Category Field: Select Sampling from the drop-down menu. Policy Arena: Select Domestic (U.S.) Only from the drop-down menu. When all fields are complete, press Continue. iii", "FSIS Compliance Guideline for Validating Cooking Instructions for Mechanically Tenderized Beef Products Table of Contents Who is this Compliance Guideline designed for?

instructions? Effective May 17, 2016, 9 CFR 317.2(e)(3)(iii) requires that the labels on raw or partially cooked needle- or blade-tenderized beef products destined for household consumers, hotels, restaurants, or similar institutions contain validated cooking instructions. FSIS added this requirement because scientific evidence shows that mechanically tenderized beef products need to be fully cooked in order to sufficiently reduce the risk pathogenic bacteria. Pathogenic bacteria may be present on the interior of mechanically tenderized beef products because any contamination on the outside of the product may be carried to the inside through penetration by needles and other devices. As a result, it is important that mechanically tenderized beef products be cooked thoroughly as opposed to \u201crare\u201d or \u201cmedium rare\u201d. Consumers often request that restaurants cook steaks \u201crare\u201d or \u201cmedium-rare\u201d. Generally, intact cuts of muscle such as steaks are rendered free of pathogenic bacteria if cooked \u201drare\u201d or \u201cmedium rare\u201d provided the steaks are seared according to the recommendations in the Food Code. According to the 2009 Food Code \u00a773401.11(C)(3), a raw or undercooked whole-muscle, intact beef steak may be served or offered for sale in a ready-to-eat form if among other things, \u201cthe steak is cooked on both the top and bottom to a surface temperature of 63oC (145oF) or above and a cooked color change is achieved on all external surfaces.\u201d Seared intact steaks may be considered a ready-to-eat food without being fully cooked because contamination with pathogenic bacteria such as Escherichia coli O157:H7 (E. coli O157:H7) and other STEC organisms, if present, would only occur on the surface of the product. As long as the external surfaces are exposed to lethality temperatures, the product can be rendered safe without thoroughly cooking the product through the interior (NACMCF, 1997). Despite the safe handling instructions on mechanically tenderized beef products to \u201ccook thoroughly,\u201d recent outbreak data indicate that for needle or blade tenderized raw beef products, consumers, restaurants, and retail stores do not always thoroughly cook these products to a temperature and time combination sufficient to destroy harmful bacteria, such as E. coli O157:H7. Indeed, in many cases, patients associated with outbreaks reported preparing or ordering steaks as \u201crare\u201d or \u201cmedium-rare.\u201d Since 2000, the Centers for Disease Control and Prevention has received reports of six outbreaks attributable to needle or blade tenderized beef products prepared in restaurants and consumers\u2019 homes. Among these outbreaks, there were a total of 176 E. coli O157:H7 cases that resulted in 32 hospitalizations and 4 cases of hemolytic uremic syndrome (HUS). Failure to thoroughly cook a mechanically tenderized raw or 1", "partially cooked beef product was a significant contributing factor in all of these outbreaks (Culpepper et al., 2009; Swanson et al., 2005). Cooking instructions for these products should inform consumers that these products need to be cooked to a specified minimum internal temperature, and should identify whether they need to be held at that minimum temperature for a specified time before consumption, i.e., rest or dwell time, so that they are thoroughly cooked. This document provides guidance on how to validate such cooking instructions. What are the minimum components of validated cooking instructions that must be on the label to comply with the requirements in 9 CFR 317.2(e)(3)(iii)? The cooking instructions must include, at a minimum: (1) The method of cooking; (2) A validated minimum internal temperature that would destroy pathogens throughout the product; (3) A statement as to whether the product cooked in the manner described also needs to be held for a specific time at the specified temperature or higher before consumption; and (4) Instruction that the

internal temperature should be measured by the use of a thermometer. The cooking instructions included on the label should be practical and easily followed by consumers. To the right is an example of cooking instructions that meet these minimum components. Note that these instructions are in addition to the Safe Handling instructions required on raw beef products in 9 CFR 317.2(l)(1). In this example, to meet requirements, an establishment would need to validate that the cooking instructions will achieve the time and temperature combination on the label (i.e., 145°F for 3 minutes). Once it validates the cooking instructions, the establishment would not need any additional scientific support to meet the first element of validation. No additional documentation would be needed because the FSIS Guidance on Safe Cooking of Non-Intact Meat Chops, Roasts, and Steaks supports that adequate reduction of For Food Safety and Quality Follow These Cooking Instructions: Gas Grill: 1) Heat gas grill on Medium-High. 2) Cook for 6 minutes to an internal temperature of 145°F as measured with a food thermometer. Flip steak over at least twice during cooking. 3) After removing from the gas grill, allow meat to rest for at least three minutes before serving. 2,"pathogens would be achieved with a desired endpoint temperature of 145°F and a rest time of 3 minutes. Are there additional instructions FSIS recommends establishments include on the label? FSIS reviewed the literature and found that achieving a consistent temperature throughout beef products is key to ensuring adequate lethality of pathogenic bacteria is achieved (Gill et al., 2013). Two factors identified in the literature that can affect even heating include the state of the product before cooking (e.g., frozen, refrigerated, or room temperature) and the amount of times during cooking steaks are turned over (i.e., flipped) (Berry, 2000; Gill et all, 2013; Luchansky, 2014). Based on these findings, FSIS recommends establishments include the following two additional instructions on the label of mechanically tenderized beef products in order to ensure that consumers achieve a consistent temperature throughout the product needed to sufficiently reduce the presence of potential pathogens: 1. "Fully thaw before cooking" FSIS recommends establishments include the instruction "fully thaw before cooking" on the labels of mechanically tenderized beef products to achieve even heating in the product. Research with patties has shown that temperatures tend to be more consistent across patties that are cooked from the thawed rather than the frozen state (Berry, 2000). Not surprisingly, other research has found that patties cooked from the frozen state take longer to achieve the target endpoint temperature than those that have been thawed (Luchansky, 2013). Even if this instruction is provided, establishments should consider conducting additional tests to assess the impact on cooking adequacy if the consumer does not fully thaw the product prior to cooking. Alternatively, two sets of validated cooking instructions could be provided: one for preparation of thawed product and one for preparation of frozen product. These practices are recommended in GMA's 2008 Guidelines for Validation of Consumer Cooking Instructions for Not-Ready-to-Eat (NRTE) Products and discussed further on page 10 of this guideline because consumers may ignore warnings and cook the product from the frozen state. When asked, consumers report cooking beef patties from the frozen state without thawing approximately 22% of the time (Phang and Bruhn, 2011). Including this instruction on the label may have additional benefits for quality as thawing frozen patties before cooking has also been found to improve sensory properties such as juiciness (BignerGeorge and Berry, 2000). 2. For mechanically tenderized steaks, "Turn steak over at least twice during cooking" For

mechanically tenderized steaks, FSIS recommends establishments also include the instruction to turn steak over at least twice during cooking so that consumers consistently achieve the desired endpoint temperature throughout the steak. This recommendation is based on research that shows turning steaks over at least twice results in more even heating and, as a result, more consistent reductions in E. coli 3", "O157:H7 than turning steaks over once (Gill et al., 2013). The recommendation to turn over mechanically tenderized steaks does not apply to other mechanically tenderized beef products such as roasts since larger cuts of mechanically tenderized beef will typically experience longer come up times contributing to additional lethality in the product over the entire cooking time. In addition, roasts and other large cuts are often cooked by consumers in moist environments that contain humidity contributing to even cooking (e.g., in cooking large cuts of meat in slow cookers with the lid in place and roasting large cuts of meat such as roasts by adding water or broth to the pan and tenting foil over the product). Consistent with this recommendation, the Food and Drug Regulations in Canada require the statement "turn steak over at least twice during cooking" on the principal display panel of mechanically tenderized steaks to achieve a consistent temperature throughout these products (Health Canada, 2014). NOTE: The final rule does not require establishments to include the instructions "fully thaw before cooking" and "turn steak over at least twice during cooking" on the label of mechanically tenderized beef products. These instructions are included in this guideline as recommendations. FSIS is recommending these additional instructions be included on the label of mechanically tenderized beef products because thawing steaks before cooking and flipping steaks over at least twice during cooking has been found to help ensure that consumers achieve a consistent temperature throughout the product. Achieving a consistent temperature throughout the product is critical to ensuring that potential pathogens in the interior of the product are sufficiently reduced. FSIS did not propose to include these instructions in the proposed rule (78 FR 34589) and is therefore, not requiring these instructions be included in the final rule. How can an establishment validate its cooking instructions? There are two main elements to validation which also apply to the process of validating cooking instructions.

**ELEMENT 1: Scientific or Technical Support (Design)** The first part to validating cooking instructions is providing scientific or technical support for the judgments made in designing the cooking instructions. The scientific support should demonstrate that: The cooking instructions provided can repeatedly achieve the desired minimum internal temperature and, if applicable, rest time and The minimum internal temperature and time at that temperature achieved by the instructions will destroy pathogens present in the product. To collect the first type of support, demonstrating that the cooking instructions can repeatedly achieve the desired minimum internal temperature and, if applicable, the rest time, the cooking instructions are generally repeatedly followed under actual consumer 4", "cooking conditions to show that the desired endpoint temperature and rest time can consistently be met. For example, if an establishment has instructions which state to cook a mechanically tenderized steak on a grill for 7 minutes in order to heat the steak to 160°F, then, put simply, the establishment would need to heat the steak on different types of grills several times to support that it actually takes 7 minutes to heat the steak to 160°F under different consumer cooking conditions. As a result, this first type of scientific support does not need to consist of microbiological data but rather should include data demonstrating the cooking instructions

consistently achieve the desired endpoint temperature under worst-case scenario conditions. It is the responsibility of the establishment to identify scientific support that demonstrates that consumers can achieve the endpoint temperature and rest time by following the cooking instructions. This type of documentation generally consists of a scientific article from a peer-reviewed journal, a published processing guideline, or data gathered in-plant or in a test kitchen. Data can be gathered anywhere the consumer cooking equipment is available. A number of journal articles have been published in which researchers have already validated cooking instructions for mechanically tenderized beef products. To assist establishments with developing cooking instructions, Attachment 1 of this guideline contains a summary of published scientific support for cooking instructions that have been found to achieve a sufficient endpoint temperature and rest time, along with the critical operational parameters included in each study. Establishments may utilize these cooking instructions on the labels of their products provided that the actual product being produced and labeled is similar to the product for which the instructions were developed. For example, if an establishment produced a 1 inch thick blade tenderized steak, the following instructions could be used as they have been validated according to the research conducted by Gill et al. (2013) provided in Attachment 1: For Food Safety and Quality Follow These Cooking Instructions: 1) Heat stainless steel skillet on electric stove to medium. 2) Add steak to skillet and cook for 26 minutes. Turn product over at least twice during cooking. 3) Cook until steak reaches an internal temperature of 145°F as measured by a food thermometer and allow to rest for 3 minutes before serving.\*\* In the research articles provided in Attachment 1, the authors determined the amount of time it would take using different cooking methods to reach different desired endpoint temperatures for steaks of different thicknesses. Only products that reached endpoint temperatures sufficient to produce a ready-to-eat product (that is one in which at least a 5-log<sub>10</sub> reduction of Salmonella and STEC organisms such as E. coli O157:H7 is achieved) are included in Attachment 1. Establishments using cooking instructions from Attachment 1 would not need to provide the original journal articles used to develop the instructions because all of the critical operational parameters have been provided in the Attachment. Therefore, if establishments utilize instructions from Attachment 1, no further scientific support is needed to meet the first element of validation. NOTE: Establishments should be aware that the cooking instructions developed from research by Luchansky et al., 2012 and provided on pages 17 and 18 of Attachment 1 are associated with a lower margin of safety because they instruct consumers to flip the product once part way through cooking. Newer research by Gill et al., 2013, shows turning steaks over at least twice results in more even heating and, as a result, more consistent reductions in E. coli O157:H7 than turning steaks over once. Cooking instructions developed from this newer research are provided on pages 19 through 21 and have been found to be associated with a greater margin of safety. The list of references provided in Attachment 1 is not exhaustive. Establishments may identify other articles published in peer-reviewed journals or other scientific support that can be used to support that cooking instructions have been validated. When selecting scientific support for cooking instructions, it is important that an establishment identify scientific support that closely matches its actual process. In order to determine that the scientific support closely matches the actual process and the cooking instructions on the label, establishments should ensure that the documentation was developed for a product KEY QUESTION Question: If I use Attachment 1 as

the scientific support for my cooking instructions, do I need additional scientific support to meet the first element of validation? Answer: No, Attachment 1 has been developed using published research. All critical operational parameters an establishment would be expected to meet are included in the Attachment. Therefore, the establishment does not need to maintain on file the original journal articles from which the instructions were developed. In addition, only cooking instructions that achieve the minimum internal temperature and, if applicable, rest time needed to destroy potential pathogens were selected. Therefore, the establishment also does not need to maintain additional scientific support for the internal temperature and, if applicable, rest time chosen. 6", "that is similar in terms of the: \u2022 Cut of beef, \u2022 Method of tenderization \u2022 Thickness \u2022 Cooking method and \u2022 Desired endpoint temperature and rest time (if applicable) that will be referenced in the cooking instructions on the label. It is important for establishments to ensure that the actual product being labeled is similar to the product studied because differences in the cut of beef, method of tenderization, thickness, and cooking method all have an impact on heat transfer and as a result, the amount of time it takes to reach the desired endpoint temperature. Therefore, if any of these parameters in the actual product or process differ from those used in the scientific support, the establishments should provide documentation as part of their validation records supporting why the desired endpoint temperature will still be reached. Such a justification could include reference to previously conducted research or scientific principles that would support that the desired endpoint temperature will still be reached. This justification is needed because the establishment cannot be sure that the desired endpoint temperature will be met if different critical operational parameters are used. If a justification cannot be provided, then additional support may be needed. For example, if an establishment produces a 2-inch thick steak, and the only available cooking instructions that have been validated are for a 1 inch steak, then the cooking instructions should not be used because it will take significantly longer to reach the desired endpoint temperature with a thicker steak (Gill, et al., 2013, Luchansky et al., 2012). The next section discusses how an establishment can validate their own cooking instructions if none are available in the literature for a similar product. In addition to identifying scientific or technical support demonstrating that the cooking instructions can repeatedly achieve the desired endpoint temperature, an establishment should also identify scientific support that demonstrates the expected level of bacterial pathogen reduction achieved when the desired endpoint temperature is reached. Such scientific support should demonstrate that the minimum internal temperature and, if applicable, rest time in the instructions (for example 160\u00b0F instantaneously) have been validated to destroy pathogens throughout the product. This means that if the product reaches the desired minimum internal temperature for the applicable rest time, at least a 5-log<sub>10</sub> reduction of Salmonella and STEC organisms such as E. coli O157:H7 will be achieved. As a result, the scientific support for the endpoint temperature and rest time should consist of or be developed from microbiological data demonstrating an adequate reduction in pathogens is achieved. NOTE: The cooking instructions provided in Attachment 1 of this guideline were developed to reach minimum internal temperature and rest time combinations found to achieve at least a 5-log<sub>10</sub> reduction of Salmonella and STEC organisms such as E. coli O157:H7. Therefore, these instructions were developed from 7", "microbiological data that demonstrate an adequate reduction in pathogens is achieved, and no further scientific support is needed. It is also the responsibility of the establishment to

identify scientific support for the endpoint temperature and, if applicable, rest time used for a product's cooking instructions. This type of documentation generally consists of a scientific article from a peer-reviewed journal, a published processing guideline, a challenge or inoculated pack study, or a regulatory performance standard. It is important to consider that not all cooking instructions have been developed to achieve a sufficient endpoint temperature, and if applicable, rest time. Often cooking instructions are developed to achieve a desired doneness of a product (i.e., medium, medium-well, or well-done). Cooking instructions for mechanically tenderized beef products should be developed to achieve desired endpoint temperatures in order to make a safe product.

According to the FSIS Guidance on Safe Cooking of Non-Intact Meat Chops, Roasts, and Steaks from April 2009 (See Attachment 2 of this guideline), products cooked to 150°F should be held or allowed to rest for at least 52 seconds to achieve at least a 5-log<sub>10</sub> reduction of Salmonella and E. coli O157:H7. Products cooked above 160°F achieve a 5-log<sub>10</sub> reduction in these pathogens instantaneously without any additional rest time. The FSIS Guidance on Safe Cooking of Non-Intact Meat Chops, Roasts, and Steaks also supports that adequate reduction of pathogens would be achieved with a desired endpoint temperature of 145°F and a rest time of 3 minutes. If establishments can validate that their cooking instructions will achieve that time and temperature combination, they would meet requirements, and no additional scientific support would be needed to meet the first element of validation. Establishments may utilize the FSIS Guidance on Safe Cooking of Non-Intact Meat Chops, Roasts, and Steaks provided in Attachment 2 of this guideline as support for the endpoint temperature and rest time, or they may provide their own scientific support for other time and temperature combinations. If establishments use other time and temperature combinations, they must demonstrate that those other combinations achieve the same results (i.e., a 5-log<sub>10</sub> reduction of Salmonella) as the time and temperature combinations in the table. This is because the time and temperature combinations in the FSIS Guidance were developed from microbiological data demonstrating an adequate reduction in pathogens is achieved.

Although the FSIS Guidance was developed using microbiological data for Salmonella, the guidance can be used to support that an adequate reduction of STEC such as E. coli O157:H7 is also achieved because Salmonella is considered an indicator for lethality. Salmonella is used as an indicator for lethality because it is more heat resistant than other pathogens such as E. coli O157:H7. Therefore, if a 5-log<sub>10</sub> reduction of Salmonella is achieved, at least a 5-log<sub>10</sub> reduction of E. coli O157:H7 should be achieved as well (Goodfellow and Grown, 1978; Line et al., 1991). In addition to the FSIS guidance, establishments may also utilize the endpoint time and temperature combinations provided in the 2013 FDA Food Code for mechanically tenderized meats in § 3-401.11(A)(2). As with the FSIS guidance, although the Food Code does not contain actual microbiological data, the 8", "time and temperature combinations were developed from microbiological data demonstrating an adequate reduction in pathogens is achieved. NOTE: The time and temperature combinations in the FSIS Guidance on Safe Cooking of Non-Intact Meat Chops, Roasts, and Steaks provided in Attachment 2 of this guideline were originally developed for FSIS regulated establishments that have a high degree of process control. Although establishments may utilize the guideline as support for the endpoint temperature and rest time of consumer cooking instructions, FSIS has determined that not all of the time and temperature combinations are practical for consumers to follow. Specifically,

the rest times associated with the temperatures less than 145°F (e.g., 144°F for 4 minutes, 143°F for 5 minutes, etc.) are not practical for consumers to maintain. Therefore, FSIS does not recommend an establishment design cooking instructions to achieve these time and temperature combinations unless it can document in its hazard analysis or decision-making documents contractual controls in place (e.g., agreements with Hotel, Restaurants, or Institutions) to ensure instructions are followed by the end user and why the establishment has concluded that these instructions will be effective. How can an establishment develop its own scientific support for its cooking instructions if a product doesn't match one of those in Attachment 1 of this guideline? If an establishment produces a product for which scientific support for cooking instructions is not readily available (for example, the product is of a different thickness or cut than one that has been studied or is partially cooked at the establishment), or if an establishment wants to provide cooking instructions for a cooking method that has not been studied, then additional scientific support will be needed. Such scientific support may be developed by collecting data in a test kitchen or other location where the cooking method (e.g., gas grill, broiler, stove top) is available for testing. Data may be collected by establishment employees or a third party, or an establishment may elect to conduct and to document a trial with consumers to monitor how well they are able to follow labeled cooking instructions. To develop scientific support for cooking instructions, the establishment should determine the temperature of the product after it is cooked following the instructions on the label. If instructions have not already been developed, the establishment can collect data during cooking to determine the length of time it takes to reach the desired endpoint temperature. As previously discussed, the endpoint temperature and if applicable, rest time should be selected to support at least a 5-log<sub>10</sub> reduction of Salmonella and STEC organisms such as E. coli O157:H7. The appropriate validation study should at least consider conditions likely to result in the lowest endpoint temperature or a worst-case scenario (NACMCF, 2006). In order to ensure the validation study represents the worst-case scenario, the following product and testing variables should be considered.

"Product variables": The method of tenderization - either needle/blade tenderized or injected - appears to affect the amount of cooking time needed to reach a desired endpoint temperature (Luchansky, et al 2011). Therefore, the product studied should be prepared using the same method of tenderization (ideally under actual in-plant conditions) as the product for which the cooking instructions are being developed.  
Thickness of the product: The thickness of the product is a critical factor for heat transfer. The thicker a product, the longer it will take for the core of the product to reach the desired endpoint temperature. Therefore, it is recommended that the thickness of products from at least three lots be measured. The validation study should be conducted using a product that represents the thickest product measured. If an establishment has a quality specification for thickness, the maximum thickness could also be used to select the thickest product to study. If an establishment packages products by portion size (e.g., 10, 12, or 14 ounces), then it should determine the variability in thickness of products packaged at that portion size and conduct the validation study using a product that represents the thickest product. It should do so because thickness is the factor that affects heat transfer. Again, products from at least three lots should be measured to determine the worst case scenario.  
Type of cut (e.g., steak or roast): Related to the thickness of the product, the type of cut can also affect heat transfer because of

differences in size, shape, presence or absence of a bone, and fat content. To account for these differences, cooking instructions for each cut should be validated separately.

Testing variables

\u2022 Method of cooking: Cooking instructions may be provided for multiple cooking methods\devices. Common methods of cooking for mechanically tenderized beef products such as steaks and roasts include cooking by conventional oven, gas grill, or stove top. When testing cooking instructions for conventional ovens, testing should be done on electric, gas, as well as convection ovens if possible to determine whether the instructions work on all types of ovens. Before beginning the validation study, a cold spot determination should be conducted to support that even in the coldest spot the desired endpoint temperature is reached. FSIS does not recommend that cooking instructions be developed for microwave ovens because of the difficulty in applying heat uniformly. For more considerations related to different cooking methods, see the Grocery Manufacturer\u2019s Association (GMA) 2008 Guidelines for Validation of Consumer Cooking Instructions for Not-Ready-to-Eat (NRTE) Products available at: [http://www.gmaonline.org/downloads/wygwam/121894\\_1.pdf](http://www.gmaonline.org/downloads/wygwam/121894_1.pdf).

10", "\u2022 State of the product at the start of cooking, e.g., frozen versus refrigerated, or room temperature: The initial temperature of the tested product should be the lowest expected temperature at the start of cooking. As recommended in GMA\u2019s 2008 Guidelines for Validation of Consumer Cooking Instructions for Not-Ready-to-Eat (NRTE) Products, even if the instructions require thawing before cooking, it may be worthwhile to consider additional tests to assess the impact on cooking adequacy if the consumer does not fully thaw the product before cooking.

Alternatively, two sets of validated cooking instructions could be provided: one for preparation of thawed product and one for preparation of frozen product.

\u2022 Multiple units: The amount of product cooked at the same time needs to be considered, particularly for products cooked in a conventional oven. The cooking instructions may need to be extended if multiple servings are cooked at once. If cooking instructions are written for cooking multiple units (for example two steaks), the instructions should be validated for the same number of units.

\u2022 Type of pan or cooking container: Establishments may also need to consider the type of pan\cooking container during the design of the validation study. Darker metals tend to heat more quickly than lighter ones. If the type of pan is not included in the cooking instructions, then the establishment should consider using a lighter pan during the validation study to represent a worst-case scenario.

\u2022 Number and location of temperature measurement sites during testing: Testing of the endpoint temperature should occur in the thickest part of the product. If possible, at least two temperature measurements should be taken per product.

\u2022 Number of replicates: In order to determine variability in the time it takes to reach the desired endpoint temperature, at least three replicates should be conducted for each type of cooking method studied. Conducting replicates is one of the KEY POINT: REPLICATES There is often confusion surrounding the principle of conducting replicates. Often times, multiple products will be tested under the same conditions at the same time (for example, multiple steaks may be placed in the same oven and cooked together); however, these would not be considered true replicates because variability in the oven conditions is not being measured. In order to determine variability in cooking, the steaks would need to be tested separately, under the same conditions, multiple times. For example, one steak would need to be cooked in the oven under the trial conditions. After the results are measured and the oven is cooled, the trial would need to be repeated again with another steak. Each piece of steak tested should be from

a different lot so that variability within the product is measured as well. 11","main principles of the scientific method and involves repeating the entire trial over again under the same conditions multiple times to determine the reproducibility of the results. Guidance is provided later in this document on how to evaluate the results from the different replicates. \u2022 Rest or dwell time after cooking: If the scientific support for the minimal internal endpoint temperature indicates a rest time is needed in order to achieve adequate reduction in pathogens, then this fact should be noted in the trial design so that the instructions are developed appropriately. A "rest or dwell time" is the amount of time the product remains at the final temperature, after it has been removed from a grill, oven, or other heat source. During the time after meat is removed from the heat source, its temperature remains constant or continues to rise, which destroys pathogens. If the product is covered during the rest time to help maintain the final temperature, this fact should be noted as well. \u2022 Rotation of product: If the product is flipped part way during cooking, this fact should be documented in the testing and included in the instructions. Testing methodology After the establishment has identified the product and testing variables, the testing methodology should be determined. If cooking instructions are already available for the product, the establishment can repeatedly prepare the product following the instructions and determine whether the desired endpoint temperature is consistently met. If instructions are not available, the establishment can collect data during cooking to determine the length of time it takes to reach the desired endpoint temperature. To make this measurement of the internal temperature during cooking, a stainless steel thermocouple can be inserted from one end into the center of the product. To achieve more accurate measurement, another stainless steel thermocouple can be inserted in the center of the product from the opposite end. The temperature can be continuously monitored with thermocouple data logger at 5 second intervals. The product can then be cooked using the desired cooking method until the desired endpoint temperature is reached, at which point the amount of time it took to reach the temperature can be recorded. If two thermocouples are used, the time recorded should be the time it takes for both thermocouples to reach the desired endpoint temperature. See Luchansky et al., 2011 and 2012 for an example of this testing methodology. In either case, the product should be prepared under the same conditions at least three separate times (i.e., three replicates should be conducted) to support the results are repeatable by consumers. Establishments may determine to conduct additional replicates after consulting with a statistician. An example of a trial that could be used to validate cooking instructions that takes these product and testing variables into account is provided in Attachment 3. 12","How to evaluate the results If labeling instructions were developed before the study is conducted, and the goal of the study was to validate whether these instructions achieved the desired endpoint temperature, when evaluating the data, if all of the temperatures taken following the instructions met or exceeded the target temperature, then the cooking instructions can be considered adequate. When not all data are at or above the target temperature a statistical analysis of the data points is recommended. As recommended in GMA\u2019s 2008 Guidelines for Validation of Consumer Cooking Instructions for Not-Ready-to-Eat (NRTE) Products, one approach is to calculate the z-value for the data. The Z-value formula is:  $Z = (\text{average temperature} - \text{target temperature}) / \text{standard deviation}$  The average temperature is calculated from all data for products cooked using the instructions being tested. The target temperature is the temperature

that the instructions are designed to achieve. The standard deviation is a calculation representing the variability or spread in the data for products cooked using the instructions being tested. The calculated Z-value is used to determine the probability that a random temperature value would be less than the target temperature by comparing it with Z-values from a statistical table (see Attachment 4). For example, using the Table in Attachment 4, a Z-value equal to or greater than 2.33 means that 99% of the time, when the product is cooked using the instructions, the temperature will be at or above the target temperature. One percent of the time (or about 1 in 100 times) the temperature will be below the target. From a public health perspective, establishments should try to achieve a Z-value greater than 2.33 to have a high degree of confidence, that when followed, the cooking instructions will result in a temperature at or above the target temperature. If instructions were not available prior to the study, and the study was used to determine the time it takes to reach the endpoint temperature, then the establishment should use the worst-case scenario result from all of the replicates as the cooking instructions. Thus, if there was variability in the length of time it took to reach the endpoint temperature, the cooking instructions should be developed using the longest amount of time needed to achieve the desired endpoint temperature. In some cases, the establishment may need to conduct statistical analyses to determine whether significant differences were found between testing scenarios. For example, if an establishment wants to provide a single set of instructions for both electric and gas ovens, the instructions should be validated using both types of cooking. The establishment should then conduct statistical analyses to determine whether there were any significant differences in the time it took to reach the desired endpoint temperature using the two methodologies. If no significant differences are found, then the establishment can conclude that a single set of instructions would be sufficient. 13", "If cooking instructions are changed for product quality reasons or if the product or testing variables are changed (e.g., the thickness of the steak increases), the new instructions should be validated to support product safety. In addition, establishments should closely monitor calls to their toll free numbers and other consumer complaints for signs that the cooking instructions are not easily followed or, when followed, do not adequately cook the product.

**ELEMENT 2: In-plant Validation Data (Execution)** Once an establishment has identified scientific support for the cooking instructions chosen, it then needs to implement the same critical operational parameters from the scientific support that were used to develop the cooking instructions. The critical operational parameters related to the product that should be implemented in the actual process include the: \u2022 Cut of beef, \u2022 Method of tenderization, and \u2022 Thickness. In order to meet the second element of validation, the establishment needs to demonstrate that the product the instructions are used for meet these critical operating parameters. To gather data demonstrating that they do, the establishment needs to collect in-plant data supporting that the cut of beef, method of tenderization, and thickness of product that bear the cooking instructions match those of the product for which the cooking instructions were developed. After collecting the in-plant validation data, the establishment should verify on an ongoing basis that the critical operational parameters continue to be met and match those used in the scientific support. It is up to the establishment to support the frequency with which the critical operational parameters are verified. These data may already be collected by establishments on an ongoing basis as part of quality specifications.

The required lethali

ties are achieved instantly when the internal temperature of a cooked meat product

reaches 158°F or above. This Time\Temperature table is based on Thermal Death Curve for Salmonella in Beef Emulsions in tubes derived from Goodfellow & Brown, 19781,2. 1 Goodfellow, S. J. and W. L. Brown. 1978. Fate of Salmonella Inoculated into Beef for Cooking. Journal of Food Protection. 41: 598-605. 2 All times that were a fraction of a minute or second was rounded up to the next whole number (e.g., 16.2 seconds for 155 °F was round up to 17 seconds. 22", "Example for Illustration Purposes Only Attachment 3: Example Validation of Conventional Oven Cooking Instructions for a Needle Tenderized Roast Validation Trial Product Summary Sheet Date: 12/5/2012 Product Name: Roast #456 Product variables Method of tenderization Needle Tenderized Thickness of the product 5 inches Type of cut Eye-round roast (3 lbs) Testing variables Method of cooking Both ovens were preheated to 350°F Electric oven \u2013 KitchenAid Model #: 5678 Serial #: LMN5678 Gas oven \u2013 LG Model #: 12345 Serial #: ABC12345 State of the product at the start of cooking, e.g., frozen versus refrigerated, or room temperature Refrigerated Multiple units Only one roast was tested at a time because this is how the consumer would ordinarily prepare the product Type of pan\cooking container The roast was cooked in a light pan (uncovered) to represent worst case scenario Number and location of temperature measurement sites during testing Two temperature measurements were taken in the center of the roast (the thermocouples were inserted into opposite ends of the roast) Number of replicates The testing methodology was repeated three times for each method of cooking (electric and gas) Endpoint temperature 150°F Rest time after cooking 1 minute Rotation of product None 23", "Example for Illustration Purposes Only Test methodology: First, a cold spot determination was conducted for each type of oven in which oven temperatures were taken in five different locations (front left, front right, back left, back right, and center) on each rack in the oven. After the cold spot determination was complete, the oven was heated to 350°F. Then product (at refrigeration temperature) was placed in the oven on a light colored pan in the location previously identified to be the coldest. Two calibrated, stainless steel thermocouples were inserted from opposite ends of the product into the center of the roast to measure the internal temperature of the roast during cooking. The temperature of the roast was continuously monitored with an eight-channel thermocouple data logger at 5 second intervals. The roast was removed from the oven when both thermocouples within the roast reached 150°F. Time was recorded at this point. The temperature of the roast was measured after the 1 minute rest time to ensure that the product temperature remained at 150°F while it was uncovered. 3 This entire procedure, beginning after the cold spot determination, was repeated three times. Results were recorded on the charts below. Results: Electric oven preheated to 350°F Time to reach 150°F Trial 1 91 minutes Trial 2 97 minutes Trial 3 90 minutes Gas oven preheated to 350°F Time to reach 150°F Trial 1 98 minutes Trial 2 89 minutes Trial 3 93 minutes A two-sample t-test was conducted and it was determined that the difference in the mean time to reach 150°F using the gas and electric oven was not statistically significant. Conclusions: A single set of instructions can be created for electric and gas ovens since the difference in time it took to reach the desired endpoint temperature was not statistically significant. Since the longest amount of time it took to reach 150°F was 98 minutes, this value will be rounded up for the instructions so that consumers are instructed to cook 3 This method was adapted from Luchansky et al. 2011 and 2012. 24", "Example for Illustration Purposes Only the product for 1 hour and 40 minutes (or 100 minutes). Consumers will also be instructed to allow the

product to rest for 1 minute. An example of the final validated cooking instructions are provided below. For Food Safety and Quality Follow These Cooking Instructions: Electric or gas oven: 1) Heat oven to 350\u00b0F. 2) Cook for 1 hour and 40 minutes to an internal temperature of 150\u00b0F as measured with a food thermometer. 3) Remove from oven and allow meat to rest for 1 minute. 25","Attachment 4: Z-Table (Cumulative Probabilities of the Standard Normal Distribution Entry) Z 0.00 0.01 0.02 0.03 0.04 0.05 0.06 0.07 0.08 0.09 -3.5 0.0002 0.0002 0.0002 0.0002 0.0002 0.0002 0.0002 0.0002 0.0002 -3.4 0.0003 0.0003 0.0003 0.0003 0.0003 0.0003 0.0003 0.0003 0.0003 -3.3 0.0005 0.0005 0.0005 0.0004 0.0004 0.0004 0.0004 0.0004 0.0004 -3.2 0.0007 0.0007 0.0007 0.0006 0.0006 0.0006 0.0006 0.0006 0.0006 -3.1 0.0010 0.0009 0.0009 0.0009 0.0009 0.0009 0.0008 0.0008 0.0008 -3.0 0.0013 0.0013 0.0013 0.0012 0.0012 0.0011 0.0011 0.0011 0.0010 0.0010 -2.9 0.0019 0.0018 0.0018 0.0017 0.0016 0.0016 0.0015 0.0015 0.0014 0.0014 -2.8 0.0026 0.0025 0.0024 0.0023 0.0023 0.0022 0.0021 0.0021 0.0020 0.0019 -2.7 0.0035 0.0034 0.0033 0.0032 0.0031 0.0030 0.0029 0.0028 0.0027 0.0026 -2.6 0.0047 0.0045 0.0044 0.0043 0.0041 0.0040 0.0039 0.0038 0.0037 0.0036 -2.5 0.0062 0.0060 0.0059 0.0057 0.0055 0.0054 0.0052 0.0051 0.0049 0.0048 -2.4 0.0082 0.0080 0.0078 0.0075 0.0073 0.0071 0.0069 0.0068 0.0066 0.0064 -2.3 0.0107 0.0104 0.0102 0.0099 0.0096 0.0094 0.0091 0.0089 0.0087 0.0084 -2.2 0.0139 0.0136 0.0132 0.0129 0.0125 0.0122 0.0119 0.0116 0.0113 0.0110 -2.1 0.0179 0.0174 0.0170 0.0166 0.0162 0.0158 0.0154 0.0150 0.0146 0.0143 -2.0 0.0228 0.0222 0.0217 0.0212 0.0207 0.0202 0.0197 0.0192 0.0188 0.0183 -1.9 0.0287 0.0281 0.0274 0.0268 0.0262 0.0256 0.0250 0.0244 0.0239 0.0233 -1.8 0.0359 0.0351 0.0344 0.0336 0.0329 0.0322 0.0314 0.0307 0.0301 0.0294 -1.7 0.0446 0.0436 0.0427 0.0418 0.0409 0.0401 0.0392 0.0384 0.0375 0.0367 -1.6 0.0548 0.0537 0.0526 0.0516 0.0505 0.0495 0.0485 0.0475 0.0465 0.0455 -1.5 0.0668 0.0655 0.0643 0.0630 0.0618 0.0606 0.0594 0.0582 0.0571 0.0559 -1.4 0.0808 0.0793 0.0778 0.0764 0.0749 0.0735 0.0721 0.0708 0.0694 0.0681 -1.3 0.0968 0.0951 0.0934 0.0918 0.0901 0.0885 0.0869 0.0853 0.0838 0.0823 -1.2 0.1151 0.1131 0.1112 0.1093 0.1075 0.1056 0.1038 0.1020 0.1003 0.0985 -1.1 0.1357 0.1335 0.1314 0.1292 0.1271 0.1251 0.1230 0.1210 0.1190 0.1170 -1.0 0.1587 0.1562 0.1539 0.1515 0.1492 0.1469 0.1446 0.1423 0.1401 0.1379 -0.9 0.1841 0.1814 0.1788 0.1762 0.1736 0.1711 0.1685 0.1660 0.1635 0.1611 -0.8 0.2119 0.2090 0.2061 0.2033 0.2005 0.1977 0.1949 0.1922 0.1894 0.1867 -0.7 0.2420 0.2389 0.2358 0.2327 0.2296 0.2266 0.2236 0.2206 0.2177 0.2148 -0.6 0.2743 0.2709 0.2676 0.2643 0.2611 0.2578 0.2546 0.2514 0.2483 0.2451 -0.5 0.3085 0.3050 0.3015 0.2981 0.2946 0.2912 0.2877 0.2843 0.2810 0.2776 -0.4 0.3446 0.3409 0.3372 0.3336 0.3300 0.3264 0.3228 0.3192 0.3156 0.3121 -0.3 0.3821 0.3783 0.3745 0.3707 0.3669 0.3632 0.3594 0.3557 0.3520 0.3483 -0.2 0.4207 0.4168 0.4129 0.4090 0.4052 0.4013 0.3974 0.3936 0.3897 0.3859 -0.1 0.4602 0.4562 0.4522 0.4483 0.4443 0.4404 0.4364 0.4325 0.4286 0.4247 -0 0.5000 0.4960 0.4920 0.4880 0.4840 0.4801 0.4761 0.4721 0.4681 0.4641 +0 0.5000 0.5040 0.5080 0.5120 0.5160 0.5199 0.5239 0.5279 0.5319 0.5359 0.1 0.5398 0.5438 0.5478 0.5517 0.5557 0.5596 0.5636 0.5675 0.5714 0.5753 0.2 0.5793 0.5832 0.5871 0.5910 0.5948 0.5987 0.6026 0.6064 0.6103 0.6141 0.3 0.6179 0.6217 0.6255 0.6293 0.6331 0.6368 0.6406 0.6443 0.6480 0.6517 0.4 0.6554 0.6591 0.6628 0.6664 0.6700 0.6736 0.6772 0.6808 0.6844 0.6879 0.5 0.6915 0.6950 0.6985 0.7019 0.7054 0.7088 0.7123 0.7157 0.7190 0.7224 0.6 0.7257 0.7291 0.7324 0.7357 0.7389 0.7422 0.7454 0.7486 0.7517 0.7549 0.7 0.7580 0.7611 0.7642 0.7673 0.7704 0.7734 0.7764 0.7794 0.7823 0.7852 0.8 0.7881 0.7910 0.7939 0.7967 0.7995 0.8023 0.8051 0.8078 0.8106 0.8133 0.9 0.8159

Raw and NRTE pork products, including all forms of fresh (i.e., raw or uncured) pork, do not need to be treated to destroy Trichinella because they are customarily wellcooked in the home or elsewhere before being served to the consumer. i FSIS USDA","Preface What is the purpose of this compliance guideline? FSIS developed this compliance guideline to assist establishments, particularly small and very small establishments, understand the available options that are effective for the prevention and control of Trichinella spiralis and other parasitic hazards, specifically, Toxoplasma gondii, in ready-to-eat (RTE) and not-ready-to-eat (NRTE) pork products. The guidance represents best practice recommendations by FSIS, based on current scientific and practical considerations, and does not represent regulatory

requirements that must be met. Establishments may choose to adopt different procedures than those outlined in the guideline, but they would need to support why or how those procedures are effective. On 5/31/18, FSIS published the final rule \u201cElimination of Trichinae Control Regulations and Consolidation of Thermally Processed, Commercially Sterile Regulations\u201d (83 FR 25302), which amends the Federal meat inspection regulations to eliminate the requirements that RTE and NRTE pork products be treated to destroy Trichina (Trichinella spiralis). FSIS removed these prescriptive regulations because they were inconsistent with the Hazard Analysis and Critical Control Point (HACCP) regulations, and are no longer necessary. Establishments now have the flexibility provided by the HACCP regulations (9 CFR Part 417) to develop appropriate science-based controls for Trichinella and other parasitic hazards in pork. All establishments producing pork products will have to determine whether Trichinella is a hazard reasonably likely to occur (RLTO) in their processes. If so, they will need to address this hazard in their HACCP system. All establishments producing pork products will need to assess whether their products are to be treated for elimination of Trichinella, special cooking instructions are necessary on the label of the products, or safe handling instructions on labels are sufficient to ensure that the products are cooked to temperatures necessary to eliminate any live Trichinella. Establishments may decide to treat their products to address Trichinella or to include special cooking instructions on labels based on how consumers typically prepare the products or the likelihood that consumers will confuse the products with RTE products. Establishments may also make decisions based on whether their suppliers participate in international trade and a voluntary preharvest pork safety program, such as the Animal and Plant Health Inspection Service\u2019s (APHIS\u2019s) U.S. Trichinae Certification Program, or another APHIS-approved validated Trichinella preharvest safety program that complies with the World Organisation for Animal Health\u2019s (OIE\u2019s) guidance<sup>1</sup> for 1 World Organisation for Animal Health Terrestrial Animal Health Code. Retrieved from [http://www.oie.int/index.php?id=169&L=0&htmfile=chapitre\\_trichinella\\_spp.htm](http://www.oie.int/index.php?id=169&L=0&htmfile=chapitre_trichinella_spp.htm)

ii", "Trichinella. OIE\u2019s guidance includes maintaining controlled management conditions for swine herds by functional separation using biosecurity measures, having two years of slaughter surveillance data to establish the compartment, auditing farms, and ensuring animal identification and traceability to the farm of origin. APHIS is working to develop standards for a program that would ensure that product for export comes from facilities that meet the international standards for Trichinella. These standards, once developed, may replace the U.S. Trichinae Certification Program. This compliance guideline follows the procedures in the Office of Management and Budget\u2019s (OMB) \u201cFinal Bulletin for Agency Good Guidance Practices\u201d (GGP). More information can be found on GGP on the Food Safety and Inspection Service (FSIS) webpage at: <https://www.fsis.usda.gov/wps/portal/footer/policies-and-links/significantguidance-documents/significant-guidance>. Who is this guideline designed for? This guideline is designed for small and very small establishments in support of the Small Business Administration\u2019s initiative to provide compliance assistance under the Small Business Regulatory Enforcement Fairness Act (SBREFA). However, all FSIS regulated meat and poultry establishments may be able to apply the recommendations in this guideline. It is important that small and very small establishments have access to the scientific and technical support and assistance they need to establish safe and effective HACCP systems. Although large establishments can benefit from the

guidance that FSIS provides, focusing the guidance on the needs of small and very small establishments provides these segments of the industry with information that may be otherwise unavailable to them. What if I still have questions after I read this guideline? If the desired information cannot be found within this compliance guideline, FSIS recommends that users search the publicly posted Questions & Answers (Q&As) in the askFSIS database or submit questions through askFSIS. Documenting these questions helps FSIS improve and refine present and future versions of the compliance guideline and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter FSIS Compliance Guideline for the Prevention and Control of Trichinella and Other Parasitic Hazards in Pork Products. Question Field: Enter question with as much detail as possible. Product Field: Select General Inspection Policy from the drop-down menu. Category Field: Select Sampling -General from the drop-down menu. iii","Policy Arena: Select Domestic (U.S.) Only from the drop-down menu. .....35 v", "FSIS Compliance Guideline for the Prevention and Control of Trichinella and Other Parasitic Hazards in Pork Products Background Trichinella is a parasite that infects both humans and animals. Swine are the primary source of *Trichinella spiralis* infected meat that is ingested by humans (Hill et al., 2012). Humans can become infected with Trichinella by consuming encysted larvae in the muscle tissue of an infected animal. Trichinellosis in humans is caused by the consumption of raw or undercooked meat products containing Trichinella larvae. The occurrence of Trichinella infection in humans due to the consumption of pork has decreased significantly in the U.S. over the past 20 years, although occasional sporadic outbreaks persist (Burke et al., 2008; Wilson et al., 2015). Much of this reduction is due to swine being raised in confinement. However, in organic, pasture raised swine that have access to rodents and wildlife infected with Trichinella, the risk of Trichinella infection to swine and subsequently humans are increased. In the United States, trichinellosis cases are reported to CDC much less frequently now than in the past. During the late 1940s, when the U.S. Public Health Service began counting cases of trichinellosis, 400 cases in the U.S. were recorded each year on average. During 20082012, a median of 15 cases per year were reported to CDC. Over the past 40 years, few cases of trichinellosis have been reported in the U.S., and the risk of trichinellosis from commercially raised and properly prepared pork is very low. The overall number of cases reported has decreased because of improved swineraising practices in the pork industry such as grain-fed swine being raised in confinement, commercial and home freezing of pork, and public awareness of the danger of eating raw or undercooked meat products.

1 KEY DEFINITIONS *Trichinella spiralis* is a parasitic nematode (roundworm) which is found in many warm-blooded carnivores and omnivores, including swine. Trichinella is transmitted from one host to another host by ingestion of muscle tissue (meat) containing cysts (encysted larval stage of this parasite). Once the larvae encyst in the muscle tissue, they can remain alive and infective for years. The symptoms of trichinellosis often occur within 2 weeks after eating contaminated meat and can last up to 8 weeks. The classic symptoms of trichinellosis include: muscle pain; fever; swelling of the face, particularly the eyes; weakness or fatigue; headache; chills; itchy skin or rash; cough; diarrhea; and constipation.", "Risk Comparing Swine Raised in Confinement Systems vs. NonConfinement Systems FSIS is aware that the risk of infection with Trichinella is increased in pasture raised swine that have access to rodents and wildlife infected with Trichinella. An increasing number of swine are being raised in non-confinement systems because of increased consumer demand for \u2018free-ranging,\u2019 \u2018organically raised,\u2019 and \u2018humanely raised\u2019 pork products (Hill et al., 2012; Honeyman et al., 2006). Feral swine are also reservoirs of infection with Trichinella for domestic swine reared in non-biosecure (or nonconfinement) areas. Raising swine outdoors poses a major risk for swine of being infected with Trichinella because it increases exposure to potentially infected reservoir hosts (Hill et al., 2012; Gamble et al., 2000; Pyburn et al., 2005). The risk of Trichinella infection in non-confinement swine can be substantially reduced by employing swine production practices that eliminate the sources of exposures to this parasitic

hazard, thereby reducing the likelihood of human infection from consumption of pork infected with *Trichinella*. An establishment may determine in its hazard analysis that *Trichinella* is not reasonably likely to occur (NRLTO) in its products if the establishment gets its pork from swine producers who participate in an APHIS-approved validated *Trichinella* preharvest safety program; such programs are considered prerequisite programs. It is important for establishments to understand that such prerequisite programs designed to support a decision in their hazard analysis, are part of their overall HACCP system. Because FSIS has removed the prescriptive *Trichinæ* control regulations, establishments have greater flexibility to choose validated control procedures and to support their use as part of their HACCP system to control *Trichinella* and other parasitic hazards in pork products. Establishments producing RTE or NRTE pork products must assess in their hazard analysis if *Trichinella* and other parasites are hazards reasonably likely to occur (RLTO) or NRLTO in their processes. Establishments must include control procedures for these parasites in their HACCP plans if they determine that the parasites are a hazard that is RLTO, including critical control points (CCPs) designed to control the parasitic hazard [9 CFR 417.2(c)(2)] and critical limits that must be met at each CCP [9 CFR 417.2(c)(3)]. Establishments may determine that the parasitic hazard is NRLTO because a prerequisite program prevents the hazard, but they must have documentation to support the decisions in their hazard analysis [9 CFR 417.5(a)(1)]. The options for preventing and controlling *Trichinella* in pork products are described in the section \u201cOptions for Preventing and Controlling *Trichinella* in Pork.\u201d When an establishment determines that a hazard, such as *Trichinella*, is NRLTO because the prerequisite program prevents the hazard, then that prerequisite program becomes part of the HACCP system. (See \u201cOption 2: Obtain Pork Products from 2\u201d, "Swine Producers who Participate in the *Trichinæ* Certification Program or another APHIS-approved validated *Trichinella* preharvest safety program\u201d for more information.) Options for Preventing and Controlling *Trichinella* in Pork Products Under HACCP regulations, establishments are required to conduct a hazard analysis to determine the food safety hazards that are RLTO in their production processes, in accordance with 9 CFR 417.2(a)(1). Establishments must list the CCPs designed to control hazards identified as RLTO [9 CFR 417.2(c)(2)] and establish critical limits that must be met [9 CFR 417.2(c)(3)]. Establishments are also required to maintain documentation that supports the decisions made in their hazard analysis as a part of their records under 9 CFR 417.5(a)(1). If establishments determine in their hazard analysis that *Trichinella* is a hazard RLTO, then they need to implement a CCP to eliminate the hazard. FSIS recommends that establishments use one of the following treatment methods described in Option 4 to control *Trichinella* in their pork products: 1) heating, 2) freezing, 3) curing, 4) high pressure processing (HPP), or 5) irradiation. Establishments will need to be specific in their HACCP plans as to which treatment method they are using, and the critical parameters being measured [9 CFR 417.5(a)(2) and 417.2(c)(3)]. Establishments will also need to validate the selected method [9 CFR 417.4(a)(1)] by demonstrating that they are able to consistently meet the specific parameters outlined in the selected treatment method. Establishments may also develop alternative *Trichinella* control procedures, as described in Option 5. As part of the hazard analysis, establishments may determine that *Trichinella* is a hazard NRLTO in their products because of the implementation of a prerequisite program. If an establishment decides to prevent *Trichinella* in their pork product(s) by implementing a prerequisite program, then it must keep documentation that

supports the decisions made in its hazard analysis as a part of its records [9 CFR 417.5(a)(1)]. Additionally, the prerequisite program should meet the following criteria: 1.Written and describes procedures that the establishment will implement to show the hazard is NRTLTO; 2.Designed to prevent the hazard from being RLTO, and the establishment maintains supporting documentation that the program has been validated (i.e., scientific or technical support and in-plant validation data); 3.Describes records that the establishment will keep demonstrating that the program is being implemented as written; 3", "4.Describes records the establishment will keep to demonstrate that the program effectively prevents the hazard (i.e., on-going verification of the decision that the hazard is NRTLTO); and 5.Describes actions the establishment will take when it fails to implement the program, or when it finds the program has failed to prevent the hazard (i.e., corrective actions in response to an unforeseen hazard as per 9 CFR 417.3(b) and as per 9 CFR 416.15 if the program is a Sanitation SOP). If the design of the prerequisite program is not consistent with the criteria described above, then the establishment likely has not met the requirements of 9 CFR 417.5(a)(1). The following prerequisite programs, as further described in Options 1-2, may be used by establishments to prevent *Trichinella* in their pork products: 1) acquire pork products from carcasses or carcass parts found to be free of *Trichinella* by a validated testing method; or 2) obtain pork products from swine producers who participate in the Trichinae Certification Program or another APHIS-approved validated *Trichinella* preharvest safety program. List of Options used to Prevent and Control *Trichinella* in Pork and Products Containing Pork Option 1: Acquire pork products from carcasses or carcass parts found to be free of *Trichinella* post-slaughter by a validated testing method Option 2: Obtain pork products from swine producers who participate in the Trichinae Certification Program or another APHIS-approved validated *Trichinella* preharvest safety program Option 3: Label NRTE pork products, including all forms of fresh pork to clearly indicate the products require additional treatment by the consumer Option 4: Treat NRTE pork products for the destruction of *Trichinella* that might be eaten rare or without thorough cooking because of the appearance of the finished product Option 5: Develop alternative *Trichinella* control procedures not included in Option 4 Option 1: Acquire pork products from carcasses or carcass parts found to be free of *Trichinella* by a validated testing method Pork products from carcasses or carcass parts that have been found to be free of *Trichinella* by a validated post-slaughter testing method are not required to be treated for 4", "the destruction of *Trichinella*. The validated testing method is a prerequisite program, and establishments may determine that *Trichinella* is NRTLTO if their product has been found to be free of *Trichinella* through post-slaughter testing using a validated method. Testing must be performed using a validated method that is equivalent to or better than the tissue digestion assay method for detecting *Trichinella* in pork (known as the Magnetic Stirrer Method for Pooled Sample Digestion), using a 5-gram sample of tongue, muscles of the face (e.g., masseter muscle), diaphragm muscles, or neck muscles. A 5-gram sample of diaphragm, foreleg, or tongue should be used for nonconfinement raised swine (e.g., feral swine, pasture-raised swine, free-ranging swine). Any process-verification testing should be performed using a validated testing method that is equivalent to or better than the digestion assay method for detecting *Trichinella* in pork. Processors should be aware of the limitations of the readily available commercial test kits that test for antibodies that may not show up for several weeks following infestation. Such test results are not acceptable or equivalent to tissue digestion methods to rule out the presence of

trichinæ in meat product. If establishments select Option 1 to control *Trichinella* in pork and products containing pork, they should be aware of the following: \u2022 The establishment must keep on file and make available to FSIS inspection program personnel (IPP) its procedure for testing, to include identifying and pooling carcasses, collecting and pooling samples, testing samples, communicating test results, retesting individual carcasses, and maintaining positive identification and clear separation of pork found to be *Trichinella*-free by testing from untested pork or *Trichinella*-positive pork. \u2022 The establishment may test in-house or may contract for testing by a private testing laboratory. Personnel conducting the testing for *Trichinella* must be certified to perform the validated testing method, and laboratories where testing is performed must be certified for *Trichinella* testing. Certifications are obtained by participation in a USDA *Trichinella* testing program such as the Agricultural Marketing Service (AMS) *Trichinæ Analyst Program* or other FSIS approved certification programs. Certification must be based on adequacy of facilities, reagents, and equipment and on demonstration of continuing competency and reliability of personnel performing the validated testing method for *Trichinella*. A certificate is provided to the establishment\u2019s analyst (i.e., the personnel certified to perform the validated testing method) and laboratory manager, and the FSIS Inspector-in-Charge (IIC) as evidence of certification. Private testing laboratories would provide certification documentation to their customer. \u2022 Sampling and sample preparation are subject to inspection by FSIS. 5", "\u2022 Tested pork or products made from tested pork must not be released as *Trichinella*-free from the official establishment without treatment until the IIC receives a laboratory report that the tested pork has tested negative for *Trichinella*. Option 2: Obtain pork products from swine producers who participate in the *Trichinæ Certification Program* or another APHIS-approved validated *Trichinella* preharvest safety program Establishments may determine that *Trichinella* is NRTL in their products if they obtain pork from swine producers that participate in the U.S. *Trichinæ Certification Program* (9 CFR Part 149), which is a prerequisite program for *Trichinella*. This is a voluntary preharvest pork safety program in which APHIS certifies pork production sites that follow all the required good production practices (GPPs) that reduce, eliminate, or avoid the risk of exposure of swine from their sites to *Trichinella*. In the U.S. *Trichinæ Certification Program*, adherence to the GPPs is verified by periodic site audits conducted by APHIS. Establishments are also required to maintain documentation that supports the decisions made in their hazard analysis for this prerequisite program as a part of their records under 9 CFR 417.5(a)(1). The key GPPs components for the U.S. *Trichinæ Certification Program* include: \u2022 Feed integrity, source and storage. \u2022 Building construction and condition as it pertains to biosecurity (i.e., swine raised in confinement). \u2022 Integrity of rodent control programs. o Prevent exposure to rodents or other wildlife infected with *Trichinella*. Rodents can serve as a reservoir host for *Trichinella*. \u2022 General management and hygiene issues as they pertain to rodent control, cannibalism and other issues. o Prevent cannibalism among swine within an infected herd. o Boots worn solely in confinement facility. Pork products from carcasses or carcass parts from swine herds that have been raised by producers that follow these GPPs, and thus are certified under the U.S. *Trichinæ Certification Program*, should still be tested at slaughter to verify that the adherence to good manufacturing practices and GPPs is resulting in the absence of *Trichinella* infection in swine from that herd. It is recommended that the slaughter facility that is processing certified swine perform process-verification testing to determine the *Trichinella*

infection status of certified swine under its control. Process-verification testing should be performed using a validated testing method that is equivalent to or better than the tissue digestion assay method for detecting *Trichinella* in pork, described in Option 1. 6", "It is important for establishments to understand that pork products originating from *Trichinella*-free certified swine is certified pork, and these products are not required to be treated for the destruction of *Trichinella*. Establishments may also determine that *Trichinella* is NRTLTO in their products if they obtain pork from swine producers that participate in an APHIS-approved validated *Trichinella* preharvest safety program that is in compliance with OIE\u2019s guidance for *Trichinella*. Participation in such a program would be a voluntary preharvest pork safety program. As a part of the record keeping required under 9 CFR 417.5(a)(1), participating establishments would need to maintain documentation to support the decisions made in their hazard analysis for this prerequisite program. Establishments would also need to have the ability to trace product back to the farm of origin. International requirements for *Trichinella* include the ability to trace product back to the farm of origin, an audit process to ensure compliance, slaughter surveillance, and adherence to GPPs that include: \u2022 Ensuring the integrity of rodent and other wildlife control and mitigation programs. o Prevent swine exposure to rodents or other wildlife infected with *Trichinella*. Rodents can serve as a reservoir host for *Trichinella*. \u2022 Ensuring the integrity of the feed source and feed storage. o Raw food waste of animal origin is not present on the farm and is not fed to pigs. o Feed is not exposed to rodents or other wildlife potentially infected with *Trichinella*. \u2022 Practicing good general management and hygiene. o Prevent cannibalism among swine within a herd. \u2022 Sourcing swine. o Pigs originate from herds officially recognized as participating in an APHISapproved preharvest safety program for *Trichinella* that meets international standards. It is important for establishments to understand that pork products originating from swine produced in facilities that meet the standards of an APHIS-approved validated *Trichinella* preharvest safety program are not required to be treated for the destruction of *Trichinella*. However, it is recommended that the slaughter facility that is processing swine perform process-verification testing to determine the *Trichinella* infection status of swine under its control. Option 3: Label NRTE pork products, including all forms of fresh pork to clearly indicate the products require additional treatment by the consumer 7", "Establishments must decide in their hazard analysis whether *Trichinella* is NRTLTO or RLTO in their production process. To support in their hazard analysis that *Trichinella* is NRTLTO in their NRTE pork products, establishments can use special labeling of products to require additional treatment by the consumer. NRTE pork products, including all forms of fresh (i.e., raw or uncured) pork, do not need to be treated to destroy *Trichinella* because they are customarily well-cooked in the home or elsewhere before being served to the consumer. If an establishment chooses to label its product to control *Trichinella*, then it should label the product so that the consumer understands that the product is raw or NRTE and needs to be fully cooked to control for *Trichinella*. The use of labeling may be generically approved by FSIS\u2019s Labeling and Program Development Staff (LPDS) in accordance with 9 CFR 412.2, unless the establishment adds a claim to the label or takes some other action that would render the label ineligible for generic approval. If the establishment has a generically approved label, it would not be necessary to subject that product to treatment for *Trichinella* if the product\u2019s label clearly indicates the raw or NRTE nature of the product and provides consumers with the

following adequate food safety information:

- 1.A prominent statement on the principal display panel to indicate that the product is NRTE, for example, "Cook Thoroughly," or "Ready to Cook;"
- 2.Cooking instructions that result in a RTE product (e.g., "Cook to an internal temperature of 145 degrees Fahrenheit as measured by a food thermometer and allow to rest for 3 minutes before serving"); and

Note: If the minimum internal temperature above appears on the principal display panel, then the prominent statement in #1 above may be omitted.

- 3.Safe handling instructions (SHIs) if the product is raw or the pork ingredient is not RTE. An example label, along with the SHIs, is provided below.

8","U.S. INSn:CT\u00a3D ANO PASSED BY DEPARTMENT OF AGAICUL TUR[ ESt38 Safe Handling Instructions This product was prepared from inspected and passed meat and/or poultry. Some food products may contain bacteria that could cause illness if the product is mishandled or cooked improperly. For protection, follow these safe handling instructions. Keep refrigerated until thawed in refrigerator or microwave. b Keep meat and poultry separate from other foods. Wash hands after handling surfaces (including boards), utensils, and/or hands after handling meat and/or poultry. ~ Cook thoroughly. ~ Keep hot foods hot!.

Refrigerate leftovers immediately or discard. Keep Frozen Smoked, Cured Pork Sausage

INGREDIENTS: Pork, water, salt, sugar, spices, and sodium nitrite Distributed by: ABS Company, City, State, 12345 COOK THOROUGHLY NET WEIGHT: 8 OZ (Principal Display Panel) Cook to an internal temperature of 145 degrees Fahrenheit as measured by a food thermometer and allow to rest for 3 minutes before serving (Back Panel) NOTE: The information in the SHIs cannot be used in lieu of the prominent statement described in #1 or the cooking directions in #2 above. These features need to be separate and distinct from the SHIs. 9","Establishments can submit labeling questions to the LPDS through askFSIS. LPDS can also be reached by telephone at 1-800-233-3935. When submitting a labeling question through askFSIS, use the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter FSIS Compliance Guideline for the Prevention and Control of Trichinella and Other Parasitic Hazards in Pork Products. Question Field: Enter your question with as much detail as possible. Product Field: Select Labeling from the drop-down menu. Category Field: Select Labeling Regulations, Policies and Claims from the drop-down menu. Policy Arena: Select Domestic (U.S.) only from the drop-down menu. When all fields are complete, press Continue and at the next screen then press Finish Submitting Question. Option 4: Treat NRTE pork products for the destruction of Trichinella that might be eaten rare or without thorough cooking because of the appearance of the finished product Establishments that determine in their hazard analysis that Trichinella is a hazard RLTO need to employ process controls to eliminate the hazard. Pork products need to be treated for the destruction of Trichinella if they are to be prepared in such a manner that the product might be eaten rare or without thorough cooking because of the appearance of the finished product. Some ingredients (e.g., annatto, red wine, paprika, red pepper, etc.) may also alter the appearance of the finished product, making it difficult for the consumer to visually determine whether the product has been fully cooked. Certain pork products that require treatment for the destruction of Trichinella are mixtures of pork with other meats and poultry; bacon wrapped products; breaded pork; raw marinated pork in dark sauces; colored pork; cured pork; and cured and smoked pork. For these products, one or more processing steps make it difficult for the consumer to visually determine whether the product has been fully cooked, such as encasing the raw pork or coloring the raw pork. NOTE: Poultry products

containing pork muscle tissue are also required to be treated for the destruction of *Trichinella* in accordance with 9 CFR 424.21(a)(3)(iii). 10", "KEY QUESTION Question: Are certain pork products, such as pork cuts, pork sausage, and bacon, required to be treated for the destruction of *Trichinella*? Answer: No. Certain pork products, including fresh unsmoked sausage containing pork muscle tissue, and pork such as bacon and jowls are classed as products that are customarily well cooked in the home or elsewhere before being served to the consumer. Therefore, these products are not required to be treated to destroy *Trichinella*. As described in \u201cOption 4,\u201d pork products need to be treated for the destruction of *Trichinella* if they are prepared in such a manner that the product might be eaten rare or without thorough cooking because of the appearance of the finished product. Additionally, certain products requiring treatment for the destruction of *Trichinella* are mixtures of pork with other meats and poultry; bacon wrapped products; breaded pork; raw marinated pork in dark sauces; colored pork; cured pork; and cured and smoked pork. For these products, one or more processing steps make it difficult for the consumer to visually determine whether the product has been fully cooked, such as encasing the raw pork or coloring the raw pork. Also, poultry products containing pork muscle tissue are required to be treated for the destruction of *Trichinella* in accordance with the requirements addressed in 9 CFR 424.21(a)(3)(iii). As previously discussed, establishments must determine in their hazard analysis whether *Trichinella* is a hazard RLTO in their production processes [9 CFR 417.2(a)(1)]. If so, then establishments must list the CCPs designed to control *Trichinella* [9 CFR 417.2(c)(2)] and the critical limits that must be met at each of the CCPs [9 CFR 417.2(c)(3)]. Also, establishments must keep documentation that supports the decisions made in their hazard analysis as a part of their records [9 CFR 417.5(a)(1)]. Further, establishments are also required to validate the selected method, in this case to control the *Trichinella* hazard, as per 9 CFR 417.4(a)(1), by demonstrating that they are able to consistently meet the specific parameters outlined in the selected treatment method. If *Trichinella* has been determined to be RLTO, then the establishment may elect to use one of the following treatment methods to destroy the parasite in its pork products: 1) heating, 2) freezing, 3) curing, 4) HPP, or 5) irradiation. As an example, an establishment may use the freezing treatment method as a CCP in its HACCP plan to eliminate *Trichinella* in its pork product where the thickness of the meat or inside dimensions of the container does not exceed 6 inches (i.e., Group 1 products \u2013 see Table 2). The critical limits for Group 1 products would be a continuous temperature no higher than 5\u00b0F for 20 days. 11", "FSIS considers these methods, when properly applied and validated, to be sufficient to destroy *Trichinella*. Establishments can also elect to develop alternative treatments for the destruction of *Trichinella*, as described in Option 5. NOTE: If an establishment is producing RTE pork products, then compliance with the lethality performance standards for the reduction of *Salmonella* will ensure the elimination of *Trichinella* because the time\temperature combinations for *Salmonella* are higher than the heat treatment for *Trichinella*. However, because there are no published studies comparing the lethality rate of *Salmonella* to the destruction of *Trichinella* in dried, salt-cured, or fermented products, FSIS cannot state with absolute certainty that the lethality performance standards for *Salmonella* in these types of products would also eliminate *Trichinella*. Therefore, if an establishment identifies *Trichinella* as a hazard that is RLTO, then the establishment will have to ensure that the process is validated and verified to effectively eliminate *Trichinella*. Critical Operational Parameters for the Methods used for the Destruction

of Trichinella in Pork Critical operational parameters are the specific conditions that the intervention must operate under for it to be effective. The interventions, or methods, used to eliminate Trichinella from pork products include heating, freezing, curing, HPP, or irradiation. The critical operational parameters important for each treatment method are listed and described below.

Time\temperature combination It is important that the time and temperature combinations adhere to the specific parameters described in \u201cHEATING,\u201d \u201cFREEZING,\u201d and \u201cCURING.\u201d The specific timetemperature parameters apply only when the product reaches and maintains temperatures evenly distributed throughout the meat. Alternative methods of heating, particularly the use of microwaves, have been shown to give variable results, with parasites not completely inactivated when product was heated to reach a prescribed end-point temperature. Establishments must maintain on file the recording of actual times and temperatures as specified in their HACCP plans, 9 CFR 417.5(a)(3). Product, including product in containers, undergoing refrigeration must be spaced in such a way to ensure a free circulation of air between the pieces of meat, layers, blocks, barrels, and tierces for the desired temperature of the meat to be promptly and uniformly reduced. Equipment settings or calibrations In accordance with 9 CFR 417.4(a)(2), establishments are required to calibrate processmonitoring instruments as part of ongoing verification activities and are required to 12","support their verification procedures and the frequencies of those procedures. Further, establishments must have records on file documenting the calibration of processmonitoring instruments, 9 CFR 417.5(a)(3). The smokehouses, drying rooms, and other compartments used in the treatment of pork must be appropriately equipped with accurate automatic recording thermometers to ensure that temperatures that effectively eliminate Trichinella are maintained. Automatic recording thermometers and the thermometers used must be calibrated periodically (frequency determined as per HACCP plan) to ensure that they are functioning accurately.

Pressure HPP is an antimicrobial treatment that exposes the product to elevated pressures, with or without the addition of heat, to inactivate Trichinella. Pork processed with HPP is placed in a sealed flexible container. The flexible container is placed in a basket or barrel and moved to a high-pressure chamber filled with a pressure-transmitting fluid, usually water, which does not contact product. The chamber is equipped with pumping and decompression systems. The action of the high pressure causes inactivation of Trichinella larvae. Establishments must follow the specific parameters in \u201cHIGH PRESSURE PROCESSING\u201d for eliminating Trichinella in pork.

Irradiation The type of radiation used in irradiating food is ionizing radiation, which includes high energy gamma rays, X-rays and accelerated electrons. For Trichinella, the process involves exposing the food product to carefully controlled amounts of ionizing radiation for a specific time to destroy the parasite. Ionizing radiation does not increase the normal radioactivity level of the food, regardless of how long the food is exposed to the radiation, or how much of an energy dose is absorbed. The types of ionizing radiation include gamma rays (from radioactive isotopes cobalt-60 or cesium-137), beta rays generated by electron beam or \u201cE-beam,\u201d and X-rays (ICGFI, 1999; Smith et al., 2004). The amount of ionizing radiation that is absorbed by the food product is called the radiation absorbed dose. Ionizing radiation is measured in units of rads (1 rad=100 erg\g) or grays (1 Gy=100 rads), with 1,000 grays equal to 1 kiloGray (kGy) (ICGFI, 1999; Smith et al., 2004). The doses used to eliminate parasitic hazards in pork are listed in \u201cIRRADIATION.\u201d

Heat is an effective

method that is used to destroy *Trichinella* in pork products. If the steps described below are followed, FSIS considers the resulting product safe from *Trichinella*. The heating method is unnecessary if an establishment is producing RTE 13", "products containing pork in compliance with the higher lethality performance standards for *Salmonella*. However, FSIS cannot state with absolute certainty that the lethality performance standards designed to reduce *Salmonella* for dried, salt-cured, or fermented products will eliminate *Trichinella*. Therefore, establishments will have to ensure the lethality process used for these types of products effectively eliminates *Trichinella*. Table 1 - Time and Temperature Combinations to Eliminate *Trichinella*

Minimum internal temperature	Minimum time	Degrees F	Degrees C	120	49.0	21			
hours	122	50.0	9.5 hours	124	51.1	4.5 hours			
minutes	132	55.6	15 minutes	134	56.7	6 minutes			
hours	126	52.2	2.0 hours	128	53.4	1.0 hour			
minutes	136	57.8	3 minutes	138	58.9	2 minutes			
hours	140	60.0	1 minute	142	61.1	1 minute			
minutes	144	62.2	Instant	1.	All parts of the pork muscle tissue should be heated according to one of the timetemperature combinations in the above table to eliminate <i>Trichinella</i> .				
3.	Time and temperature must be monitored using a calibrated device that meets the requirements provided in \u201cGeneral Instructions for Recording Thermometers\u201d at the end of this section.								
4.	Time, in combination with temperatures of 138\u00b0F to 143\u00b0F, need not be monitored if the product's minimum thickness exceeds 2 inches (5.1 cm), and refrigeration of the product does not begin within 5 minutes of attaining 138\u00b0F.								
4.	The establishment should use procedures that ensure the uniform heating of the product. It is important that each piece of sausage, each ham, and other product treated by heating in water be kept entirely submerged throughout the heating period. The establishment must ensure the largest pieces in a lot, the innermost links of bunched sausage or other massed articles and pieces placed in the coolest part of a heating cabinet or compartment or vat, be included in the temperature tests.								
4.	14", "FREEZING <i>Trichinella</i> is susceptible to prolonged periods of cold temperatures. If one of the following procedures is followed, FSIS considers the resulting product safe from <i>Trichinella</i> . At any stage of preparation and after preparatory chilling to a temperature of no more than 40\u00b0F or preparatory freezing, all parts of the muscle tissue of pork or product containing such tissue should be subjected continuously to a temperature no more than one of those specified in Table 2. The duration of such freezing at the specified temperature is dependent on the thickness of the meat or inside dimensions of the container.								
Table 2 - Required Period of Freezing at Temperature Indicated	Temperature	\u00b0F	Group 1 Products	Group 2 Products (Days)	(Days)				
5	20	30	-10	10	20	-20	6	12	1.
Group 1 comprises product in separate pieces not exceeding 6 inches in thickness, or arranged on separate racks with the layers not exceeding 6 inches in depth, or stored in crates or boxes not exceeding 6 inches in depth, or stored as solidly frozen blocks not exceeding 6 inches in thickness.	2.	Group 2 comprises product in pieces or layers, the thickness of which exceeds 6 inches but not 27 inches. When the product is placed in containers, including tierces, barrels, kegs, and cartons, the containers do not exceed 27 inches in depth. Thus, the product will receive the effects of the refrigeration\freezing throughout its entire mass in the timeframes specified.	3.	The product, including in containers, undergoing such refrigeration must be spaced in such a way in the freezer as to ensure a free circulation of air between the pieces of meat, layers, blocks, boxes, barrels, and tierces so that the desired temperature of the meat will be promptly and uniformly reduced to no higher than 5\u00b0F, -10\u00b0F, or 20\u00b0F, as respectively per product group.	4.	As an alternative to the			

methods prescribed in Table 2, the treatment may consist of commercial freeze-drying or controlled freezing, at the center of the meat pieces, in accordance with the times and temperatures specified in Table 2A. 15", "Note: To control for *Trichinella* in whole pork carcasses, the product needs to be frozen solid. Table 2A - Alternate Periods of Freezing at Temperatures Indicated Maximum internal temperature Minimum Time Degrees F Degrees C 0 -17.8 106 hours -5 -20.6 82 hours -10 -23.3 63 hours -15 -26.1 48 hours -20 -28.9 35 hours -25 -31.7 22 hours -30 -34.5 8 hours -35 -37.2 1½ hour 5. During the period of freezing, the product should be stored in the rooms or compartments where the lots can be controlled and not comingled so that the product does not leave the rooms or compartments until it is fully treated. The rooms or compartments containing product undergoing freezing need to be equipped with accurate thermometers placed at or above the highest level at which the product undergoing treatment is stored and away from refrigerating coils. 6. Pork product that has been frozen needs to be controlled in such a way as to ensure that the treated product is designated and not comingled with untreated product. CURING Curing is another method recognized for the control of *Trichinella*. The curing methods described below are effective for destroying *Trichinella* in sausage, capocollo, coppa, hams, pork shoulder picnics, boneless pork loins, and loin ends. If any of these methods are followed for the appropriate products, then FSIS would consider the products safe from *Trichinella*. 16", "There is a great variety of processes used to prepare cured pork products (sausages, hams, pork shoulders, and other RTE products). All processes currently approved for commercial use have been tested to determine their efficiency in killing *Trichinella*. In the curing process, product is coated or injected with a salt mixture and allowed to equalize at refrigerated temperatures. Following equalization, product is dried, or smoked and dried, at various temperature\time combinations. The curing process involves the interaction of salt, temperature, and drying times to reach a desired water activity, percent moisture, or brine concentration. Unfortunately, no single or even combination of parameters achieved by curing has been shown to correlate definitively with *Trichinella* inactivation (Gamble et al, 2012). All cured products should be processed by validated methods, such as those described in this section, \u201cCURING.\u201d 1.Sausage The sausage may be stuffed in animal casings, hydrocellulose casings, or cloth bags. During any stage of treating the sausage to destroy live *Trichinella*, except as provided in Sausage Treatment Method 5, these coverings should not be coated with paraffin or like substance, nor should any sausage be washed during any prescribed period of drying. In the preparation of sausage, one of the following methods may be used: Sausage Treatment Method No. 1 -Drying The meat should be ground or chopped into pieces not exceeding three-fourths of an inch in diameter. A dry curing mixture containing not less than 3 1½ pounds of salt to each hundredweight of the unstuffed sausage should be thoroughly mixed with the ground or chopped meat. After being stuffed, sausage having a diameter not exceeding 3 1½ inches, measured at the time of stuffing, should be held in a drying room not less than 20 days at a temperature not lower than 45\u00b0F, except in the case of the variety of sausage known as pepperoni. If in casings not exceeding 1 3/8 inches in diameter measured at the time of stuffing, the period of drying may be reduced to 15 days. In no case, however, should the sausage be released from the drying room in less than 25 days from the time the curing materials are added, except that sausage of the variety known as \u201cpepperoni,\u201d if in casings not exceeding the size specified, may be released at the expiration of 20 days from the

time the curing materials are added. Sausage in casings exceeding 3 1/2 inches, but not exceeding 4 inches, in diameter at the time of stuffing should be held in a drying room not less than 35 days at a temperature not lower than 45 °F, and in no case, should the sausage be released from the drying room in less than 40 days from the time the curing materials are added to the meat. Sausage Treatment Method No. 2 Smoked, then Dried The meat should be ground or chopped into pieces not exceeding three fourths of an inch in diameter. A dry curing mixture containing not less than 3 1/3 pounds of salt to each hundredweight of the unstuffed sausage should be thoroughly mixed with the 17", "ground or chopped meat. After being stuffed, sausage having a diameter not exceeding 3 1/2 inches, measured at the time of stuffing, should be smoked not less than 40 hours at a temperature not lower than 80°F, and finally held in a drying room not less than 10 days at a temperature not lower than 45°F. In no case, however, should the sausage be released from the drying room in less than 18 days from the time the curing materials are added to the meat. Sausage exceeding 3 1/2 inches, but not exceeding 4 inches, in diameter at the time of stuffing, should be held in a drying room, following smoking as indicated above, not less than 25 days at a temperature not lower than 45°F, but in no case, should the sausage be released from the drying room in less than 33 days from the time the curing materials are added to the meat. Sausage Treatment Method No. 3 Held in Pickle Curing Medium, then Dried The meat should be ground or chopped into pieces not exceeding three-fourths of an inch in diameter. A dry-curing mixture containing not less than 3 1/3 pounds of salt to each hundredweight of the unstuffed sausage should be thoroughly mixed with the ground or chopped meat. After adding the salt and other curing materials and before stuffing, the ground or chopped meat should be held at a temperature not lower than 34 °F for not less than 36 hours. After being stuffed, the sausage should be held at a temperature not lower than 34°F for an additional period of time sufficient to make a total of not less than 144 hours from the time the curing materials are added to the meat, or the sausage should be held for the time specified in a pickle curing medium of not less than 50° strength (salometer reading) at a temperature not lower than 44°F. Finally, sausage having a diameter not exceeding 3 1/2 inches, measured at the time of stuffing, should be smoked for not less than 12 hours. The temperature of the smokehouse during this period at no time should be lower than 90°F; and for 4 consecutive hours of this period the smokehouse should be maintained at a temperature not lower than 128°F. Sausage exceeding 3 1/2 inches, but not exceeding 4 inches, in diameter at the time of stuffing should be smoked, following the prescribed curing, for not less than 15 hours. The temperature of the smokehouse during the 15-hour period should at no time be lower than 90°F, and for 7 consecutive hours of this period the smokehouse should be maintained at a temperature not lower than 128°F. In regulating the temperature of the smokehouse for the treatment of sausage under this method, the temperature of 128°F should be attained gradually during a period of not less than 4 hours. Sausage Treatment Method No. 4 Dried (After Stuffing - May be Heated or Smoked, or Both Heated and Smoked) The meat should be ground or chopped into pieces not exceeding one-fourth of an inch in diameter. A dry curing mixture containing not less than 2 1/2 pounds of salt to each hundredweight of the unstuffed sausage should be thoroughly mixed with the ground or chopped meat. After adding the salt and other curing materials and before stuffing, the ground or chopped sausage should be held as a compact mass, not more

than 6 inches in depth, at a temperature no lower than 36°F for not less than 10 days. At the termination of the holding period, the sausage should be stuffed in casings or cloth bags not exceeding 3 1/3 inches in diameter, measured at the time of stuffing. After being stuffed, the sausage should be held in a drying room at a temperature not lower than 45 °F for the remainder of a 35-day period, measured from the time the curing materials are added to the meat. At any time after stuffing, if the establishment's operator deems it desirable, the product may be heated in a water bath for a period not to exceed 3 hours at a temperature no lower than 85°F, or subjected to smoking at a temperature no lower than 80°F, or the product may be both heated and smoked as specified. The time consumed in heating and smoking, however, should be in addition to the 35-day holding period specified. Sausage

Treatment Method No. 5 May be Coated with Paraffin while Held The meat should be ground or chopped into pieces not exceeding three-fourths of an inch in diameter. A dry curing mixture containing not less than 3 1/3 pounds of salt to each hundredweight of the unstuffed sausage should be thoroughly mixed with the ground or chopped meat. After being stuffed, the sausage should be held for not less than 65 days at a temperature not lower than 45°F. The coverings for sausage prepared according to this method may be coated at any stage of the preparation before or during the holding period with paraffin or other substance approved by the Administrator. Sausage Treatment Method No. 6 Held for Two Time Periods (Holding Period and a Drying Period) (A) Basic Requirements. The meat should be ground or chopped into pieces not exceeding three-fourths of an inch in diameter. A dry-curing mixture containing not less than 3.33 pounds of salt to each hundred-weight of the unstuffed sausage, excluding the weight of dry ingredients, should be thoroughly mixed with the ground or chopped meat. After the curing mixture has been added, the sausage should be held for two-time periods, a holding period and a drying period. The holding period will be for a minimum of 48 hours at a room temperature not lower than 35°F. This holding period requirement may be fulfilled totally or in part before the drying period and then the remainder, if any, after the drying period or as an extension of the drying period. During the drying period, the sausage should be held in a drying room at a temperature not lower than 50°F (10.0°C) for a period determined by Tables 3, 3A, and 3B. The length of the drying period, established in Sausage Treatment Method No.6 (A) may be modified as provided in Sausage Treatment Method No.6 (B) or (C). Table 3 -Sausage Drying Room Times by Sausage Treatment Method No. 6 Diameter of casing at time of stuffing1 Days in drying room2 Up to: 1 inches 14 1 1/2 inches 15 2 inches 16 2 1/2 inches 18 3 inches 20 3 1/2 inches 23 4 inches 25 19", "4 1/2 inches 30 5 inches 35 5 1/2 inches 43 6 inches 50 1 The drying room times for flattened or oval sausages should use a diameter derived by measuring the circumference and dividing by 3.14 (pi). 2 Drying room time may be modified as set forth in Tables 3B and 4. (B) Reduction in Drying Room Time. During the holding period, the sausage may be smoked or fermented. If the temperature is increased to 70°F (21.1°C) or higher, while the sausage is being held after adding curing materials but before the drying period, the subsequent drying room times prescribed for this method may be reduced according to the schedule in Table 3B. No interpolation of values is permissible. Table 3A -Percentage Reduction in Drying Room Time (Table 3) Permitted by Holding Times and Temperatures Prior to Drying1 Minimum Temperature2 Minimum Time (hours) 24 48 72 96 120 70°F (21.1°C) 4 9 14 19 24 75°F (23.9°C) 5 12 19 26 33 80°F (26.7°C) 8 18 28 38 48 85°F

(29.5\u00b0C) 10 25 39 53 67 90\u00b0F (32.2\u00b0C) 15 35 55 75 95 95\u00b0F  
(35.0\u00b0C) 23 49 74 98 1003 100\u00b0F (37.9\u00b0C) 37 88 1003 100 100 105\u00b0F  
(40.6\u00b0C) 57 1003 100 100 100 110\u00b0F (43.3\u00b0C) 90 1003 100 100 100  
120\u00b0F (48.9\u00b0C) 1003 100 100 100 100 1 In computing the days to be deducted, the number with any fraction should be rounded to the next lower whole number and should be deducted from the required total drying time. Example: Sausage stuffed in 3inch diameter casing requires 20 days in the drying room (from Drying Room Times, Table 3). If allowed to ferment, after addition of curing materials, at 80\u00b0F for 48 hours, the 20 day drying time may be reduced 18% (from Table 3A). Eighteen percent of 20 days equals 3.6 days. Twenty days minus 3 days equals 17 days. The total drying time required in the drying room, therefore, will be 17 days. 2 Either room temperature or internal product temperature should be used for sausages that will be subsequently dried to a moisture-protein ratio of 2.3: 1 or less. Internal product temperature should be used for all other sausages. 3 Trichinella will be destroyed during fermentation or smoking at the temperature and length of time indicated. Therefore, no drying room period is required for products so treated. (C)Reduced Salt Content-Drying Room Times. 20", "Salt content of less than 3.33 pounds for each hundredweight of sausage formulation, excluding dry ingredients, (such as salts, sugars, and spices), may be permitted provided the drying time is increased according to the schedule contained in Table 3B. Table 3B - Reduced Salt Content-Drying Room Times [Required percentage increase in drying room time (Table 3) for added salt of less than 3.33 pounds per hundredweight of sausage] Minimum pounds of salt added to sausage1 Percent increase in drying room time2 3.3 1 3.2 4 3.1 7 3.0 10 2.9 13 2.8 16 2.7 19 2.6 22 2.5 25 2.4 28 2.3 31 2.2 34 2.1 37 2.0 40 1Calculate the salt content for column 1 as follows: Multiply the pounds of salt in the sausage formulation by 100. Then divide this number by the total weight of sausage formulation minus the weight of dry ingredients and round down to the next lowest 0.1%. The percent salt may be substituted for pounds of salt. Example: 120 lbs. pork, 3.56 lbs. salt, 2 lbs. spices, 0.5 lbs. wine, 1 lb. water and starter culture, 0.8 lbs. sugar, .012 lbs. sodium nitrite total weight is 127.872 lbs. (3.56 x 100)\/(127.872 -3.56 \u2013 2 -.8 -.012) = 356\121.5 = 2.93 pounds of salt added to sausage Therefore, the sausage drying time must be increased by 13 percent. 2 In computing the days to be added to the required total drying time, fractions should be rounded to the next higher whole number and added to the required total drying time. Example: Sausage stuffed in 3 1\u20442 inch diameter casing requires 23 days in the drying room (from Drying Room Times, Table 3). If the quantity of salt added per hundredweight of sausage is 2 pounds instead of 3.33 pounds, the drying room time must be increased by 40 percent (from Reduced Salt Content-Drying Room Times, Table 3B), or 9.2 days. The 9.2 is rounded up to 10 days and is added to the 23 days to equal 33 days. The total drying time required in the drying room for the scenario presented, therefore, will be 33 days. Sausage Treatment Method No. 7 \u2013 Holding, Heating, and Drying Treatment Dry Sausages. (A)General Requirements. The establishment should use meat particles reduced in size to no more than 1\u20444 inch in diameter. The establishment should add a curing mixture containing no less than 2.7 pounds of salt per hundred pounds of meat and mix it 21", "uniformly throughout the product. The establishment should hold, heat, and dry the product according to paragraph (B) or (C) below. (B)Holding, Heating, and Drying Treatment, Large Sausages. Except as permitted in (C)below, the establishment should subject sausages in casings not exceeding 105 mm in diameter, at the

time of stuffing, to all of the following minimum chamber temperatures and time periods. Table 3C -Treatment Schedule for Sausages 105 Millimeters (4 1\8 inches) or Less in Diameter

Minimum chamber temperature	Minimum time (hours)	(\u00b0F)	(\u00b0C)	50	10	12	90	32.2	1
-----------------------------	----------------------	-----------	-----------	----	----	----	----	------	---

100	37.8	1	110	43.3	1	120	48.9	1	125	51.7	7
-----	------	---	-----	------	---	-----	------	---	-----	------	---

Following the preceding treatment, the establishment should dry the sausages at a temperature not lower than 50\u00b0F

(10\u00b0C) for not less than 7 days. (C)Heating and Drying Treatment, Small Sausages.

Alternatively, the establishment may subject sausages in casings not exceeding 55 mm in diameter, at the time of stuffing, to all of the following minimum chamber temperatures and time periods. Table 3D -Treatment Schedule for Sausages 55 Millimeters (2 1\8 inches) or Less in Diameter

Minimum chamber temperature	Minimum time (hours)	(\u00b0F)	(\u00b0C)	50	10	12	100	37.8	1	125	51.7	6
-----------------------------	----------------------	-----------	-----------	----	----	----	-----	------	---	-----	------	---

100	37.8	1	125	51.7	6
-----	------	---	-----	------	---

Following the preceding heat treatment, the establishment should dry the sausages at a temperature not lower than 50\u00b0F (10\u00b0C) for not less than 4 days.

2.Capicollo (Capicola, Capacola) Boneless pork butts for capocollo should be cured in a dry curing mixture containing no less than 4 1\2 pounds of salt per hundredweight of meat for a period of no less than 25 22", "days at a temperature no lower than 36\u00b0F. If the curing materials are applied to the butts by the process known as churning, a small quantity of pickle may be added. During the curing period the butts may be overhauled (turned over for the application of additional cure) according to any of the usual processes of overhauling, including the addition of pickle or dry salt if desired. The butts should not be subjected during or after curing to any treatment designed to remove salt from the meat, except that superficial washing may be allowed. After being stuffed, the product should be smoked for a period of not less than 30 hours at a temperature not lower than 80\u00b0F, and should finally be held in a drying room for not less than 20 days at a temperature not lower than 45\u00b0F.

3. Coppa Boneless pork butts for coppa should be cured in a dry curing mixture containing no less than 4 1\2 pounds of salt per hundredweight of meat for a period of no less than 18 days at a temperature no lower than 36\u00b0F. If the curing mixture is applied to the butts by the process known as churning, a small quantity of pickle may be added. During the curing period the butts may be overhauled according to any of the usual processes of overhauling, including the addition of pickle or dry salt if desired. The butts should not be subjected during or after curing to any treatment designed to remove salt from the meat, except that superficial washing may be allowed.

After being stuffed, the product should be held in a drying room for not less than 35 days at a temperature not lower than 45\u00b0F.

4. Hams and Pork Shoulder Picnics In the curing of hams and pork shoulder picnics, one of the methods below should be used.

For calculating days per pound, the establishment should use the weight of the heaviest ham or picnic in the lot. Ham and Pork Shoulder Picnics Method No. 1 \u2013 Dry Salt Curing Process

The hams and pork shoulder picnics should be cured by a dry salt curing process for not less than 40 days at a temperature no lower than 36\u00b0F. The products should be laid down in salt, not less than 4 pounds to each hundredweight of product, the salt being applied in a thorough manner to the lean meat of each item. When placed in cure, the products may be pumped with pickle if desired. At least once during the curing process, the products should be overhauled and additional salt applied, if necessary, so that the lean meat of each item is thoroughly covered. After removal from cure, the products may be soaked in water at a temperature no higher than 70\u00b0F for not more than 15 hours, during which time the water may be changed once, but the products should not be subjected to any other treatment

designed to remove salt from the meat except that superficial washing may be allowed. The products should finally be dried or smoked at a time and temperature not less than a combination prescribed in Table 3F, titled Ham and Pork Shoulder Picnics Method No. 2. Ham and Pork Shoulder Picnics Method No. 2 \u2013 Controlled Temperature Methods for, Curing (other than Bag Curing) and Bag Curing followed by Drying (A)Curing (other than Bag Curing) 23", "Establishments should cure hams and shoulders by using a cure mixture containing not less than 70 percent salt by weight to cover all exposed muscle tissue and to pack the hock region. Total curing time consists of a mandatory cure contact time and an optional equalization time. (B)Cure Contact Time Establishments should keep exposed muscle tissue coated with the cure mixture at least 28 days but for no less than 1.5 days per pound of ham or shoulder. This is referred to as the cure contact time. Overhaul is optional during the cure contact time if the exposed muscle tissue remains coated with the curing mixture.

(C)Equalization The establishment may provide an equalization period after the minimum cure contact time in (B) above to permit the absorbed salt to permeate the product's inner tissues. Equalization is the period after the excess cure has been removed from the product at the end of the cure contact period up until the product is placed in the drying room and the drying period begins. The total curing time (cure contact plus equalization should be at least 40 days and in no case less than 2 days per pound of an uncured ham or shoulder. (D)Removing Excess Cure After the required cure contact period, the establishment may remove excess cure mixture from the product's surface mechanically or by rinsing up to 1 minute with water, but not by soaking. (E)Bag Curing. Bag curing is a traditional ham curing technique in which the manufacturer wraps the ham and all the cure mixture together in Kraft paper then hangs each ham individually. The paper keeps the extra cure mixture in close contact with the product making reapplication of salt unnecessary, and it protects the product from mites and insects. Establishments may employ the bag curing method as an alternative to (A) through (D) above. An establishment which elects to use the bag curing method should apply a cure mixture containing at least 6 pounds of salt per 100 pounds of uncured product. The establishment should rub the curing mixture into the exposed muscle tissue, pack the hock region with the curing mixture, and use uncoated wrapping paper to wrap the product together with any remaining curing mixture. The bag-cured product should remain wrapped throughout the curing period and may or may not remain wrapped during the drying period. In any case, the curing period should be at least 40 days but not less than 2 days per pound of an uncured ham or shoulder. After curing, the cured product should be exposed to a drying time and temperature prescribed in Table 3F. (F)Curing Temperature During the curing period the establishment should use one of the following procedures: (1) The establishment should control the room temperature at not less than 35\u00b0F (1.7\u00b0C) nor greater than 45\u00b0F (7.2\u00b0C) for the first 1.5 days per pound of an uncured ham or shoulder, and not less than 35\u00b0F (1.7\u00b0C) nor greater than 60\u00b0F (15.6\u00b0C) for the remainder of the curing period. (2) The establishment should monitor 24", "and record daily product temperature. The room temperature need not be controlled but days on which the product temperature drops below 35\u00b0F (1.7\u00b0C) should not be counted as curing time. If the product temperature exceeds 45\u00b0F (7.2\u00b0C) within the first period of 1.5 days (per pound of an uncured ham or shoulder) or if the product temperature exceeds 60\u00b0F (15.6\u00b0C), during the remainder of the curing period the establishment should

cool the product back to the appropriate temperature for the curing period as described above.

(3) The establishment should begin curing product only between the dates of December 1 and February 13. The room temperature need not be controlled, but the establishment should monitor and record daily room temperatures, and days in which the room temperature drops below 35°F (1.7°C) should not be counted as curing time. (G)Drying After the curing period, establishments should use one of the following three procedures for drying. (1) The establishment should subject the product to a controlled room temperature for a minimum time and minimum temperature combination prescribed in Table 3F or for a set of such combinations in which the total of the fractional periods (in column 4 of Table 3F) exceeds 1.5. (2) Establishments using uncontrolled room temperatures should monitor and record the internal product temperature. The drying period should be complete when, from the days which can be counted as curing time, one of the time\temperature combinations of Table 3F is satisfied or when the total of the fractional values for the combinations exceeds 1.5. (3) Establishments using uncontrolled room temperatures should dry the product for a minimum of 160 days including the entire months of June, July, and August. This procedure is obviously dependent on local climatic conditions and no problem exists with respect to current producers who use this procedure. Future applicants should demonstrate that their local monthly average temperatures and the local monthly minimum temperatures are equal to or warmer than the normal average temperatures and normal minimum temperatures compiled by the National Oceanic and Atmospheric Administration for Boone, North Carolina, station 31-0977, 1981 through 2010. Table 3E -Monthly Temperature (\u00b0 F) for Boone NC, 1981-2010 Jan. Feb. Mar. Apr. May June July Aug. Sep. Normal average temperatures 31.5 34.0 40.5 49.0 57.5 65.0 68.5 67.5 61.0 Normal minimum temperatures 21.0 23.0 29.0 37.0 46.0 54.0 58.0 57.0 50.0 1 https://www.currentresults.com/Weather/North-Carolina/Places/boone-temperatures-bymonth-average.php 25","Drying Times and Temperatures for Trichinella Inactivation in Hams and Shoulders Table 3F - Minimum Drying Days at a Minimum Temperature\* Minimum drying temperature Minimum days at drying temperature Fractional period for one day of drying Degrees F 130 Degrees C 54.4 1.5 .67 125 51.7 2 .50 120 48.9 3 .33 115 46.1 4 .25 110 43.3 5 .20 105 40.6 6 .17 100 37.8 7 .14 95 35.0 9 .11 90 32.2 11 .091 85 29.4 18 .056 80 26.7 25 .040 75 23.9 35 .029 \*Interpolation of these times or temperatures is not acceptable; establishments wishing to use temperatures or times not in this Table should first validate their efficacy. Ham and Pork Shoulder Picnics Method No. 3 -Controlled Temperature Methods for Drying Curing (A)Cure Establishments should cure hams and shoulders by using a cure mixture containing not less than 71.5 percent salt by weight to cover all exposed muscle tissue and to pack the hock region. Establishments may substitute potassium chloride (KCl) for up to half of the required salt on an equal weight basis. (B)Curing Establishments should apply the cure at a rate of not less than 5.72 pounds of salt and KCl per hundred pounds of fresh meat. The cure should be applied in either three or four approximately equal amounts (two or three overhauls) at separate times during the first 14 days of curing. (C)Cure Contact Time Establishments should keep the product in contact with the cure mixture for no less than 2 days per pound of an uncured ham or shoulder but for at least 30 days. Establishments should maintain the curing temperature at no less than 35°F (1.7°C) during the cure contact time. 26","(D)Equalization After the cure contact period, establishments should provide an added equalization period of no less than 1 day per pound of an uncured ham or shoulder but at least

14 days. Equalization is the time after the excess cure has been removed from the product, the end of the cure contact period, and before the drying period begins. Establishments may substitute additional cure contact days for an equal number of equalization days. (E) Removing Excess Cure After the required cure contact period, the establishment may remove excess cure mixture from the product's surface mechanically or by rinsing up to 1 minute with water, but not by soaking. (F) Drying After the curing period, establishments should use one of the controlled temperature methods for drying listed in Ham and Pork Shoulder Picnics Method No. 2 of this subparagraph. Ham and Pork Shoulder Picnics Method No. 4 \u2013 Dry Curing at a Minimum Temperature of 55\u00b0F (13\u00b0C) for at Least 150 Days (A) Curing The establishment should cure the ham to a minimum brine concentration of 6 percent by the end of the drying period. Brine concentration is calculated as 100 times the salt concentration divided by the sum of the salt and water concentrations. Percent brine =  $100 \times [\text{salt}] / ([\text{salt}] + [\text{water}])$  The Agency will accept the brine concentration in the biceps femoris as a reasonable estimate of the minimum brine concentration in the ham. (B) Drying and Total Process Times The establishment should dry the cured ham at a minimum temperature of 55\u00b0F (13\u00b0C) for at least 150 days. The total time of drying plus curing should be at least 206 days. (C) Ensuring an Acceptable Internal Brine Concentration (1) To establish process compliance, the establishment should take product samples from the first 12 lots of production as follows: From each lot, (i) One sample should be taken from each of 5 or more hams; (ii) Each sample should be taken from the biceps femoris. As an alternative to the use of the biceps femoris, the Agency will consider other methods of sampling dry cured hams to determine the minimum internal brine concentration, as long as the establishment submits data and other information to establish the alternative method\u2019s sufficiency to the processing authority; (iii) Each sample should weigh no less than 100 grams; (iv) The samples should be combined as one composite sample and sealed in a water vapor proof container; (v) The composite sample should be submitted to an accredited laboratory to be analyzed for salt and water content using validated methods. If the time between sampling and submittal of the composite sample to the accredited laboratory will exceed 8 hours, then the establishment should "freeze" the composite sample immediately after the samples are combined; (vi) Once the laboratory results for the composite sample are received, the manufacturer should calculate the internal brine concentration by multiplying the salt concentration by 100 and then dividing that figure by the sum of the salt and water concentrations; (vii) Compliance is established when the samples from the first 12 lots of production have a minimum internal brine concentration of 6 percent. Lots being tested to establish compliance should be held until the internal brine concentration has been determined and found to be at least 6 percent. If the minimum internal brine concentration is less than 6 percent, the lot being tested should be held until the establishment brings the lot into compliance by further processing. (2) To maintain compliance through on-going verification, the establishment should take samples, have the samples analyzed, and perform the brine calculations as set forth above at a minimum for one lot every 13 weeks. Lots being tested to maintain compliance as part of on-going verification do not need to be held. If the minimum internal brine concentration is less than 6 percent in a lot being tested as part of on-going verification, the establishment must take corrective action and develop and propose steps acceptable to FSIS to ensure that the process is corrected. (3) Accredited laboratory results and the brine calculations should be placed on file at the establishment and available for

review by FSIS inspection as HACCP verification records. Ham and Pork Shoulder Picnics Method No. 5 -Dry Curing at a Minimum Temperature of 110°F (43°C) for at Least 4 Days

(A)Curing The establishment should cure the ham to a minimum brine concentration of 6 percent by the end of the drying period. Brine concentration is calculated as 100 times the salt concentration divided by the sum of the salt and water concentrations. Percent brine =  $100 \times [\text{salt}] / ([\text{salt}] + [\text{water}])$  The Agency will accept the brine concentration in the biceps femoris as a reasonable estimate of the minimum brine concentration.

(B)Drying and Total Process Times The establishment should dry the cured ham at a minimum temperature of 110°F (43°C) for at least 4 days. The total time of drying plus curing should be at least 34 days.

(C)Ensuring an Acceptable Internal Brine Concentration

(1)To establish process compliance, the establishment should take product samples from the first 12 lots of production as follows: From each lot, (i) One sample should be taken from each of 5 or more hams; (ii) Each sample should be taken from the biceps femoris. As an alternative to the use of the biceps femoris, the Agency will consider other methods of sampling the dry cured hams to determine internal brine concentration, if the establishment validates the alternative sampling method. (iii) Each sample should weigh no less than 100 grams; (iv) The samples should be combined as one composite sample and sealed in a water vapor proof container; (v) The composite sample should be submitted to an accredited laboratory to be analyzed for salt and water content using validated methods. If the time between 28", "sampling and submittal of the composite sample to the accredited laboratory will exceed 8 hours, then the establishment should freeze the composite sample immediately after the samples are combined; (vi) Compliance is established when the samples from the first 12 lots of production have a minimum internal brine concentration of 6 percent. Lots being tested to establish compliance should be held until the internal brine concentration has been determined and found to be at least 6 percent. If the minimum internal brine concentration is less than 6 percent, the lot being tested should be held until the establishment brings the lot into compliance by further processing.

(2) To maintain compliance through on-going verification, the establishment should take samples, have the samples analyzed, and perform the brine calculations as set forth above at a minimum from one lot every 13 weeks. Lots being tested to maintain compliance as part of on-going verification do not need to be held. If the minimum internal brine concentration is less than 6 percent in a lot tested to maintain compliance, the establishment must take corrective action and develop and propose steps acceptable to FSIS to ensure that the process is corrected.

(3) Accredited laboratory results and the brine calculations should be placed on file in the establishment and available to FSIS inspection for review.

5.Boneless Pork Loins and Loin Ends In place of heating or freezing to destroy live Trichinella in boneless loins, the loins may be cured for a period of not less than 25 days at a temperature not lower than 36°F using one of the following methods:

Boneless Loins Method No. 1 -Application of Dry Salt Curing Mixture Application of a dry salt curing mixture containing no less than 5 pounds of salt to each hundredweight of meats.

Boneless Loins Method No. 2 -Application of Pickle Solution Application of a pickle solution of not less than 80° strength (salometer); pickle solution should be applied to achieve not less than 60 pounds of pickle to each hundredweight of meat.

Boneless Loins Method No. 3 -Application of Pickle Solution added to the Dry Salt Cure Application of a pickle solution added to the dry salt cure prescribed as Boneless Loins Method No. 1 in this section provided the pickle solution is not less than 80° strength (salometer). After removal from

the cure, the loins may be soaked in water for not more than 1 hour at a temperature not higher than 70°F or washed under a spray but should not be subjected, during or after the curing process, to any other treatment designed to remove salt. Following curing, the loins should be smoked for not less than 12 hours. The minimum temperature of the smokehouse during this period at no time should be lower than 100°F, and for 4 consecutive hours of this period the smokehouse should be maintained at a temperature not lower than 125°F. Finally, the product should be held in a drying room for a period of no less than 12 days at a temperature no lower than 45°F.

6. Country Ham, Country Style Ham, Dry Cured Ham, Country Pork Shoulder, Country Style Pork Shoulder, "Country Ham, Country Style Ham, or Dry Cured Ham, and Country Pork Shoulder, Country Style Pork Shoulder, or Dry Cured Pork Shoulder are the uncooked, cured, dried, smoked or unsmoked meat food products made respectively from a single piece of meat conforming to the definition of "Country Ham"\u201d, or from a single piece of meat from a pork shoulder. These products must be treated for the destruction of live Trichinella using tested and approved methods. These products are prepared by the dry application of salt (NaCl), or by the dry application of salt (NaCl) and one or more of the optional ingredients listed below. These products may not be injected with curing solutions or placed in curing solutions. Listed below are 4 dry application options.

(1) The entire exterior of the ham or pork shoulder should be coated by the dry application of salt or by the dry application of salt combined with other ingredients as permitted in paragraph (d) of this section.

(2) Additional salt, or salt mixed with other permitted ingredients, may be reapplied to the product as necessary to insure complete penetration.

(3) When sodium or potassium nitrate, or sodium or potassium nitrite, or a combination thereof, is used, the application of salt should be in sufficient quantity to ensure that the finished product has an internal salt content of at least 4 percent.

(4) When no sodium nitrate, potassium nitrate, sodium nitrite, potassium nitrite or a combination thereof is used, the application of salt should be in sufficient quantity to ensure that the finished product has a brine concentration of not less than 10 percent or a water activity of not more than 0.92.

The optional ingredients for these products are:

(1) Nutritive sweeteners, spices, seasonings and flavorings; and

(2) Sodium or potassium nitrate and sodium or potassium nitrite.

General Instructions for Recording Thermometers

When necessary to comply with heating, freezing, and curing treatment requirements described in this section, the smokehouses, drying rooms, and other compartments used in the treatment of pork to destroy live Trichinella must be suitably equipped, by the operator of the official establishment, with accurate automatic recording thermometers. Equipment such as automatic recording thermometers or any thermometers used in drying rooms, and other compartments must be checked periodically to make sure they are functioning accurately.

Special Consideration for Certain Processes

That do not rely on High Temperatures to Control Trichinella in Pork

Certain processes, including those used to produce dried, salt-cured, or fermented products, do not rely on high temperatures to control Trichinella. Establishments need to ensure that further controls are in place to control Trichinella when such processes are used to produce these types of pork products. An establishment that processes a dried, 30", "salt-cured, or fermented\acidified product must address Trichinella in their HACCP system, and must also have written documentation to support the decisions made in their hazard analysis. An establishment must validate its process

(i.e., either CCPs or prerequisite programs) used to eliminate *Trichinella* when it is determined to be RLTO in the production process. As previously discussed in \u201cCURING,\u201d the effectiveness of curing to eliminate *Trichinella* larvae is dependent upon a combination of various processing parameters and on the product formulation; specifically, on the temperature and time of fermentation\drying and the salt level, respectively. Unfortunately, no single or even combination of parameters achieved by curing has been shown to correlate definitively with *Trichinella* inactivation (Gamble et al, 2012). All cured products should be processed by validated methods, such as those described in this section, \u201cCURING.\u201d HIGH PRESSURE PROCESSING (HPP) HPP is an antimicrobial treatment for use on meat, poultry, and processed egg products. HPP exposes food to elevated pressures, with or without the addition of heat, to inactivate microorganisms and extend microbiological shelf life. HPP treatment has been shown to be effective in eliminating *Trichinella spiralis*. In one study (Porto-Fett et al., 2010), HPP treatment of either 483 or 600 megapascals (MPa) for 1.0 or 0.5 min, respectively, was effective in inactivating *Trichinella spiralis* larvae in masseter muscle (about 3.4 log larvae\g) collected from infected swine. Therefore, it is recommended that a HPP treatment of a minimum of 483 MPa for 1 minute be used to eliminate *Trichinella* in pork. (Note \u2013 300 MPa = 29,007 psi (pounds per square inch); 483 MPa = 70,053 psi; and 600 MPa = 87,022 psi.) IRRADIATION Treatment of fresh pork with 40 - 50 krad (0.4 \u2013 0.6 kGy) of cesium-137 has been proven to render *Trichinella* completely non-infective. Irradiation with cobalt-60 or high energy x-rays at this same level should also be effective for inactivating these parasites. Option 5: Develop alternative *Trichinella* control procedures not included in Option 4 Establishments may decide to develop alternative procedures to control *Trichinella*. If so, establishments must ensure that their alternative procedures are properly validated. FSIS developed FSIS Compliance Guideline HACCP Systems Validation to provide establishments with assistance in meeting the validation requirements in 9 CFR 417.4 and to ensure that their HACCP systems are properly validated. 31", "Control of Other Parasitic Hazards in Pork Products Producers of RTE or NRTE pork products must also assess in their hazard analysis whether other parasites in addition to *Trichinella* are hazards that are RLTO in their production processes (9 CFR 417.2). If establishments determine that other parasites represent a hazard that is RLTO, then they must include control procedures for these parasites in their HACCP plans. Options 4-5 may be used to control other parasites in addition to *Trichinella* in pork products. Further, establishments are required to have documentation that supports the decisions made in their hazard analysis as a part of their records in accordance with 9 CFR 417.5(a)(1). As with *Trichinella*, establishments must list the CCPs designed to control other parasites [9 CFR 417.2(c)(2)] and the critical limits that must be met at each of the CCPs [9 CFR 417.2(c)(3)]. Establishments may determine in their hazard analysis that other parasites are NRLTO in their pork products if they are prevented by using a prerequisite program. If this is the case, Options 1-3 may be used to prevent other parasites in the establishment\u2019s pork products. In addition to *Trichinella*, *Toxoplasma gondii* (*Toxoplasma*) is a protozoan parasite of public health significance. *Toxoplasma* can cause toxoplasmosis, and infects most species of warm-blooded animals, including humans. Members of the family Felidae (domestic cats and their relatives) are the primary host for *Toxoplasma*. Felids can contaminate the KEY DEFINITIONS Toxoplasmosis is caused by the protozoan parasite *Toxoplasma gondii* (*Toxoplasma*). *Toxoplasma* infects most species of warm blooded animals, including humans, and can cause the disease toxoplasmosis. The only known definitive hosts for

Toxoplasma are members of family Felidae (domestic cats and their relatives). Members of the cat family are infected by eating animals infected with cysts of Toxoplasma parasites. Cats can also become infected by ingesting Toxoplasma eggs (oocysts) from contaminated food or water. Toxoplasma completes its life cycle in the cat, which produces millions of Toxoplasma eggs in its stool. Once outside of the cat, the eggs mature and become infectious for people and other animals. The tissue form of Toxoplasma (a microscopic cyst consisting of bradyzoites, a slower reproducing form contained in tissue cysts) can be transmitted to humans by food.

People become infected by: \u2022 Eating undercooked, contaminated meat (especially pork, lamb, and venison) \u2022 Accidental ingestion of undercooked, contaminated meat after handling it and not washing hands thoroughly (Toxoplasma cannot be absorbed through intact skin; however, Toxoplasma cysts containing bradyzoites can be inadvertently ingested from small bits of meat on the hands, and Toxoplasma tachyzoites have been shown to penetrate intact mucous membranes). \u2022 Eating food that was contaminated by knives, utensils, cutting boards, or other foods that had contact with raw, contaminated meat.

32", "environment by excreting the environmentally resistant stage of this parasite, the oocyst, in their feces (Jones et al., 2012). Domestic food animals, including swine, can be infected by Toxoplasma, and infected animals can harbor Toxoplasma cysts in muscle tissue. Humans can become infected by ingesting tissue cysts from raw or undercooked meat (Hill et al., 2010).

Toxoplasmosis is one of the most common parasitic infections in humans. Toxoplasma is the second leading cause of death due to foodborne illnesses in the United States, accounting for an estimated 327 deaths annually. Toxoplasma is also the fourth leading cause of hospitalizations related to foodborne illnesses, accounting for an estimated 4,428 hospitalizations annually (Scallan et al., 2011). The risk of infection with Toxoplasma is significantly increased in pasture raised swine that are exposed to cat feces in soil, grass, feed, or water (Jones et al., 2012). In the U.S., the prevalence of Toxoplasma in confinement raised swine is approximately 2.7% (Hill et al., 2010). For swine raised in pastures, the prevalence has been reported to be between 50-100% (Gamble et al., 2000). The risk of infection in swine that are raised outdoors is increased because of potential exposure to soil contaminated with Toxoplasma oocysts (Hill et al., 2012; Hill et al., 2010). Compliance with the HACCP regulations for RTE products will ensure the reduction of Toxoplasma. However, there are no certification programs to address the risk of Toxoplasma infection in swine

(<http://porkgateway.org/resource/toxoplasma/>). Prevention of Toxoplasma infection in swine is achieved through GPPs on the farm, including: \u2022 Creating a level of biosecurity that reduces or eliminates exposure of swine to cats and wildlife (e.g., bobcats, raccoons, skunks, and opossums) that may be infected with Toxoplasma. o Eliminating feral cats and securing feed, water, and swine areas from access by cats. The contribution of cats to the spread of Toxoplasma infection in swine cannot be overemphasized. \u2022 Establishing and maintaining an effective rodent control program. \u2022 Preventing cannibalism among swine within an infected herd through the prompt removal of dead swine. \u2022 Changing or thoroughly washing boots before entering barns to avoid tracking in oocysts. \u2022 Preventing deliberate or inadvertent feeding of raw or undercooked meat scraps. There is no available direct testing method that can be performed at slaughter for Toxoplasma. If the establishment identifies Toxoplasma as a hazard RLTO, then the establishment will have to use a validated process that effectively eliminates this parasitic hazard. The methods for heating, freezing, HPP,

and irradiation that are used to eliminate *Trichinella* in pork products are also sufficient to eliminate *Toxoplasma* from pork products. For *Toxoplasma*, HPP treatment of equal to or greater than 300 MPa for 33", "30 seconds is effective in eliminating *Toxoplasma* tissue cysts in ground pork (Lindsay et al., 2006). NOTE: The available information on the effect of various curing processes on *Toxoplasma* is limited and additional studies are needed to determine the effectiveness of curing for the destruction of *T. gondii* in pork and pork products. However, pumping of pork products with salt solutions containing 2% NaCl or \u22651.4% potassium or sodium lactate has been shown to inactivate *T. gondii* tissue cysts in pork (Gamble et al, 2012). 34", "References Burke, R., Masuoka, P., and Murrell, K.D. 2008. A: The labels of raw and partially cooked needle- or blade-tenderized beef products destined for household consumers, hotels, restaurants, or similar institutions will have to bear validated cooking instructions, including: \u2022 the cooking method; \u2022 that these products need to be cooked to a specified minimum internal temperature; \u2022 whether the product needs to be held for a specified time at that temperature or higher before consumption to ensure that potential pathogens are destroyed throughout the product; and \u2022 a statement that the internal temperature should be measured by a thermometer (9 CFR 317.2(e)(3)(iii)). These instructions should be practical and easily followed by consumers. Establishments can meet these requirements by including the method (e.g., grilling or baking), the minimum internal temperature, and the applicable dwell time, without including specifics on the cooking time and temperature. For example, \u201cGrill until product reaches 145F, as measured by a food thermometer, and hold the product at or above that temperature for 3 minutes\u201d would meet the requirements of this rule. Establishments may wish to include additional descriptive instructions that will make the labels more useful to consumers; however, FSIS will not require additional information on the product labels. To make the information more useful to consumers, establishments may wish to include the temperature setting of the cooking device, time to complete cooking, whether the product needs to be flipped during cooking, the amount of time to cook on each side exposed to the heat source, recommendations to thaw the product, if applicable, or recommendations to measure the temperature in thickest part of the product, etc. 1", "As part of validation, establishments must have scientific support that demonstrates the cooking method provided in the instructions can repeatedly achieve the desired minimum internal temperature and time at that temperature. Validated cooking instructions that include such details as part of the cooking method are provided in Attachment 1 of the FSIS Compliance Guideline for Validating Cooking Instructions for Mechanically Tenderized Beef Products. In addition, the times and temperatures included in Attachment 2 of the guidance are also validated, so establishments do not have to do

additional work to validate them. However, attachment 2 does not include information concerning the cooking method. Q2: To meet requirements for validated cooking instructions on the labels of mechanically tenderized raw beef products, can producers use a grid or table format to display cooking times and temperatures based on product thickness? See the example below. A: Yes. Below is an example of how a chart could be used on labels of mechanically tenderized product to meet these requirements. Cook the following size steaks on a grill for the time indicated until the cooked steak reaches 145 as measured with a meat thermometer. Then allow the product to rest for 3 minutes.

Size (Thickness)	Cooking time
0.5"	1 \u00bd min, flip and cook for 1 \u00bd min
1.0"	1 \u00bd min, flip and cook for 2 min
1.5"	2 min, flip and cook for 2 min
2.0"	2 \u00bd min, flip and cook for 2 \u00bd min
2.5"	2 \u00bd min, flip and cook for 3 min
3.0"	3 min, flip and cook for 3 min
3.5"	3 min, flip and cook for 4 min

Q3: If a Federal establishment mechanically tenderizes a larger beef cut that is sold to hotels, restaurants, and institutions where it is fabricated into smaller cuts and cooked, how should the Federal establishment validate its cooking instructions to comply with 9 CFR 317.2(e)(3)(iii)? A: The cooking instructions included on the label should be practical and easily followed by the customer. If possible, the Federal establishment should have knowledge of the types of cuts fabricated and cooked by the hotels, restaurants, and 2", "institutions it supplies to and provide validated cooking instructions for those cuts. If an establishment does not have knowledge of the types of products its customers cook, then it may choose to include one of the validated cooking instructions provided in Attachment 1 of the FSIS Compliance Guideline for Validating Cooking Instructions for Mechanically Tenderized Beef Products. on pages 17-21. The instructions have been provided for steaks of common thicknesses and therefore, represent cuts that would commonly be cooked by hotels, restaurants, and institutions.

..... 9 2","Preface What is the purpose of this Compliance Guideline? The purpose of this compliance guideline is to help industry determine which statements are permitted on the labeling of their products and the criteria for their use. The Food Safety and Inspection Service (FSIS) ensures that the labeling of meat, poultry and egg products is truthful and not misleading. FSIS considers labeling bearing any reference to Omega fatty acids to be a special statement or claim. The regulations require establishments to submit all labels bearing special statements or claims to the Agency\u2019s Labeling and Program Delivery Staff for evaluation and approval before use. However, once a label with a statement on Omega fatty acids is approved, there are many types of changes to the label that are generically approved and don\u2019t require submission to the Agency for approval prior to use (for example, change in net weight, label color, vignettes, cooking instructions, and the addition of information that is not considered a special statement or claim). The key for making the change generically is that the change cannot affect the special statement or claim (see slide 40 on the following PowerPoint Presentation Generic Label Approval). Who is this guideline designed for? This guidance is for establishments that are designing or modifying meat, poultry or egg product labels with statements related to Omega fatty acids. What changes have been made to the guidance from the last version? FSIS previously issued guidance on omega fatty acids claims on July 11, 2007. FSIS has updated the guideline to include further details and explanations on the different types of claims and a key-points reference chart. How can I comment on this guideline? FSIS is seeking comments on this guideline as part of its efforts to continuously assess and improve the effectiveness of policy documents. All interested persons may submit comments regarding any aspect of this document, including but not limited to: content, readability, applicability, and accessibility. The comment period will be 60 days and the Agency will update the document in response to the comments. Comments may be submitted by either of the following methods: Federal eRulemaking Portal Online submission at regulations.gov: This Web site provides the ability to type short comments directly into the comment field on this Web page or attach a file for lengthier comments. Go to <http://www.regulations.gov> and follow the online instructions at that site for submitting comments. 3","Mail, including - CD-ROMs, and hand- or courier-delivered items: Send to Docket Clerk, U.S. Department of Agriculture (USDA), FSIS, Patriots Plaza 3, 1400 Independence Avenue SW, Mailstop 3782, 8-163A, Washington, DC 20250-3700. All items submitted by mail or electronic mail must include the Agency name, FSIS, and document title: Food Safety and Inspection Service Statement of Labeling Guideline on Omega Fatty Acid Claims April 2016. Comments received will be made available for public inspection and posted without change, including any personal information, to <http://www.regulations.gov>. Although FSIS is requesting comments on the guidance and may update it in response to comments, the guidance reflects FSIS\u2019s current position, and establishments may start using it now. What if I still have questions after I read this guideline? If the desired information cannot be found within the Compliance Guidance, FSIS recommends that users search the publicly posted Questions & Answers (Q&As) in the askFSIS database or submit questions through askFSIS. Documenting the questions helps FSIS improve and refine present and future versions of the Compliance Guidance and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in

the fields provided: Subject Field: Enter FSIS Labeling Guideline on Omega Fatty Acid Claims April 2016 Question Field: Enter question with as much detail as possible Product Field: Select Labeling from the drop-down menu Category Field: Select Labeling Regulations, Policies and Claims from the dropdown menu Policy Arena: Select Domestic (U.S.) only from the drop-down menu When all fields are complete, press Continue. 4","KEY-POINTS REFERENCE CHART Claim Type Permitted Examples Criteria and Requirements for Approval FACTUAL STATEMENTS (fatty acid content from naturally occurring food sources) Yes (requires FSIS approval under 9CFR 412.1) - \u201cX grams of Omega-3 Fatty Acids per serving from canola oil\u201d - \u201cX milligrams of Omega-3 Fatty Acids per serving from flax seed in breading\u201d 1) Omega fatty acid content cannot come from fortification; 2) Include the nutrition facts panel on label ; 3) Provide data to support Omega fatty acid content; plus 4) Name the food(s) responsible for the omega fatty acid content. FACTUAL STATEMENTS (fatty acid content from raising animals with naturally occurring foods added to feed) Yes (requires FSIS approval under 9CFR 412.1) - \u201cX milligrams of CLA (Conjugated Linoleic Acid) per serving\u201d - \u201cX grams of Omega-3 Fatty Acids per serving\u201d 1) Omega fatty acid content cannot come from fortification; 2) Include the nutrition facts panel on label; 3) Provide data to support Omega fatty acid content; plus 4) Provide feed formulation and animal raising documentation. LEVEL CHARACTERIZATION No - \u201cGood Source of Omega-3 Fatty Acids\u201d - \u201cMore than X grams of Omega-3 Fatty Acids\u201d These statements are not permitted because there are no defined claims for Omega fatty acids. COMPANY\BRAND NAMES (Trademarked company\brand name associated with omega fatty acids) Yes (in signature line only; requires FSIS approval under 9CFR 412.1) - \u201cOmega 3 Company\u201d Signature line is placed on information panel and is not given undue prominence. TRADEMARKED SYMBOLS\LOGOS (Trademarked symbols\logos associated with omega fatty acids) No These symbols and similar logos are not permitted because there are no defined claims or synonyms for Omega fatty acids 5","Omega Fatty Acid Claims on the Labeling of Meat, Poultry and Egg Products TYPES OF OMEGA FATTY ACIDS This guidance document applies to making factual statements for Omega-3 fatty acids, Omega-6 fatty acids, and Omega-9 fatty acids. It is also applicable for statements that identify specific Omega fatty acids by name, for example, Alpha-Linolenic Acid (ALA), which is a specific omega-3 fatty acid or Conjugated Linoleic Acid (CLA), which is a specific Omega-6 fatty acid. FACTUAL STATEMENTS FSIS permits factual statements on the labeling of meat, poultry, and egg products that declare the amount of Omega fatty acids per serving, provided: 1) Establishments obtain sketch approval through FSIS, LPDS for Labeling that includes Omega fatty acid statements or any reference (direct or implied) to omega fatty acids; 2) The product is not fortified to provide the Omega fatty acid content, 3) The labeling bears a nutrition facts panel in compliance with 9 CFR 317.309, 381.409, or 590.411(e) to identify the serving size of the product, 4) Data documenting the Omega fatty acid content per labeled serving is provided with the label application submitted to LPDS for approval, and 5) The labeling includes a statement identifying the type and amount of Omega fatty acid(s) per serving and the common or usual name of the food source(s)1 from which the Omega fatty acids are obtained (for example, \u201cX milligrams of Omega-3 Fatty Acids per serving from flax seed in breading\u201d). NOTE: See label example 1 When the level of Omega fatty acids is integral in the animal tissue as a result of specialized diets fed to animals, for example, grass fed cattle or raising chickens on a feed formulated with flaxseeds or other whole food sources1 with

naturally occurring (indigenous) Omega fatty acids, the same criteria above apply except that the food source<sup>1</sup> of the Omega fatty acid does not need to be declared on the labeling. For example, grass fed beef might include the statement "\u201cXmg of Omega-6 fatty acids per serving.\u201d In this situation, documentation to support the specialized feeding formula and raising plan for the animal will also need to be included as part of the label application submitted for approval. When making statements about specific Omega fatty acids, use the full fatty acid name with the statement not just the abbreviation, for example, "\u201cXmg Conjugated Linoleic Acid (CLA) per serving\u201d, (on grass fed beef) or prominently link the abbreviated name to the full name with an asterisk or other symbol on the same label panel as the statement.

1 Commonly used foods sources with naturally occurring (indigenous) Omega fatty acids include: fish oil, canola oil, flaxseeds, and walnuts. When adding omega fatty acid sources to animal feeds the food sources would also include plant material such as grass.

6", "For example, "\u201cXmg of CLA\* per serving\u201d displayed on same panel as "\u201c\*Conjugated Linoleic Acid.\u201d Grams and milligrams The amount of the Omega fatty acids per serving on the label may be expressed either as the number of milligrams per serving or the number of grams per serving. The number of grams may be declared to the nearest one thousandth gram, for example, "\u201c0.125 grams Omega-3 fatty acids per serving from flax seed.\u201d NOTE: See label example 2 LEVEL CHARACTERIZATION STATEMENTS FSIS will not approve statements that declare or imply that the product is a good or excellent source of Omega fatty acids per serving. The nutrition labeling regulations in Title 9, Code of Federal Regulations (9 CFR), Subpart B, Section 317.313(b), for red meat products, Subpart Y, Sections 381.413(b), for poultry products, and Title 21 CFR Subpart A, Section 101.13(b) clearly state that \u201cA claim which, expressly or by implication, characterizes the level of a nutrient (nutrient content claim) of the type required in nutrition labeling \u2026, may not be made on a label or in labeling of that product unless the claim is made in accordance with the applicable provisions in this subpart.\u201d Therefore, without regulations defining such claims, the use of statements with expressed Omega-3 fatty acid claims, including, but not limited to "\u201cGood Source of Omega-3 Fatty Acids\u201d and "\u201cExcellent Source of Omega-3 Fatty Acids,\u201d cannot be approved. Likewise, labeling for meat, poultry, and egg products that bear claims that imply that the level of Omega fatty acids in a product is high or place significance on a specific level of Omega Fatty Acids, including, but not limited to "\u201cContains X grams of Omega-3 Fatty Acids,\u201d "\u201cMore than X grams of Omega-6 Fatty Acids\u201d and "\u201cFortified with X grams of Omega-9 Fatty Acids,\u201d "\u201cWith\u2026\u201d, "\u201cProvides\u2026\u201d, "\u201cPacked with\u2026\u201d, etc., cannot be approved.

TRADEMARKS, AND COMPANY NAMES Trademarked company brand names, trademarked symbols or phrases, and statements included in ad-copy on labeling that declare or imply that the product is a good or excellent source of Omega fatty acids per serving, or declare or imply a particular level of Omega fatty acids per serving using a similar wording a level of Omega fatty acids in a product cannot be approved. One exception, is that the company name may be labeled as part of the signature line for compliance with 9 CFR 317.2(g), 381.122, and 590.411 (c) (2) provided the signature line is only displayed on the information panel in normal size font so that it is not given undue prominence which would cause the use of the company name to be a false or misleading. For additional information about FSIS labeling policies and programs, including Generic Label Approval, please review the FSIS Web Site at:

http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatory-compliance/labeling/ or contact the Labeling and Program Delivery Staff at (301) 504-0878 or (301) 504-0879. 7","Label Example 1 [Back to reading] Label Example 2 [Back to reading]

.....	13","1 Purpose The purpose of this guideline is to explain to a country\u2019s Central Competent Authority (CCA) how to request and maintain an equivalence determination in order to export meat (including beef, veal, pork, lamb, mutton, goat, and fish of the order Siluriformes), poultry (including chickens, turkeys, ducks, geese, guineas, ratites, or squabs), or egg products (including pasteurized or

unpasteurized egg products) to the United States (US). The CCA is a country's national government authority that is responsible for ensuring the safety and truthful labeling of the food supply. This guideline provides information about the: - Background on the US equivalence process within the context of the Agreement on the Application of Sanitary and Phytosanitary Measures and the World Trade Organization; - Information on the different types of equivalence determinations; and - The steps that countries are to follow to obtain an equivalence determination from FSIS.

What is Equivalence? Equivalence is the process of determining whether a country's food safety inspection system achieves FSIS's appropriate level of protection for public health as applied domestically in the US. Additionally, the country's food safety inspection system is to provide standards equivalent to FSIS to ensure other non-food safety requirements (such as humane handling, accurate labeling, and assurance that meat, poultry, or egg products are not economically adulterated) are met. This means that the country is not required to develop and implement the same procedures that the US does, but rather the country must objectively demonstrate how its procedures meets the US level of protection.

Countries wishing to become eligible to export meat, poultry, or egg products to the US must demonstrate that they have a regulatory food safety inspection system that is equivalent to that of the US. The following is an example of when FSIS determined that a country's raw beef products inspection system was equivalent and the country's food safety procedures were different than the US procedures.

Example of an Equivalent Food Safety Procedure Different from FSIS

FSIS has a food safety objective-based criterion that requires the CCA to ensure that raw beef products are free of shiga toxin-producing *Escherichia coli* (STEC) at the end of the production process. In the US, beef slaughter and processing establishments use a combination of antimicrobial treatments and sanitary dressing procedures to control STEC. However, other countries prohibit the use of antimicrobial treatments and have submitted requirements that raw beef establishments are to implement robust sanitary dressing procedures with additional controls and government verification procedures to prevent STEC. In this situation, the CCA has verification procedures (including rigorous microbial sampling) that demonstrate sanitary dressing procedures ensure that raw beef products are free of STEC at the end of the production process. Additionally, the CCA's controls include a focus on carcasses as well as other conditions (high event periods) and classes of raw products that collectively increase the likelihood of detecting STEC if present. Based upon the evaluation of the CCA's verification procedures, controls, and receipt and evaluation of ongoing microbial results from the CCA, FSIS has determined this approach to be equivalent because the CCA demonstrates that it meets the food safety criterion.

Equivalence Background

Determining equivalence of a country's food safety inspection system is important because it protects public health and facilitates trade. An equivalence determination of an exporting country's regulatory food safety inspection system for meat, poultry, or egg products is a prerequisite for trade for the United States Department of Agriculture's (USDA) Food Safety and Inspection Service (FSIS). USDA-FSIS is the US CCA responsible for regulating and inspecting meat, poultry, and egg products. FSIS implements an equivalence process to ensure that US treaty obligations under the World Trade Organization's (WTO) Agreement on the Application of Sanitary and Phytosanitary

Measures (SPS Agreement) is met. The SPS Agreement sets out the basic international rules for food safety, animal, and plant health standards. FSIS ensures during the equivalence process that the following SPS Agreement standards are met through the implementation of the following principles: science, risk assessments, transparency, harmonization, and equivalence. To ensure that meat, poultry, or egg products (including imported products) do not pose any public health risks to US consumers, FSIS implements the Federal Meat Inspection Act (FMIA), Poultry Products Inspection Act (PPIA), Egg Products Inspection Act (EPIA), Humane Methods of Slaughter Act (HMSA), and regulations under Title 9 Code of Federal Regulations (CFR) Parts 300-590. FSIS ensures that a country's food safety inspection system addresses FSIS' food safety regulatory-based objectives. Food safety regulatory-based objectives are food safety goals for preventing the occurrence of an identified food safety hazard. The criteria by which FSIS assesses the equivalence of a country's food safety inspection system can be found under Title 9 CFR §7327.2 (for meat products), §7557.2 (for fish of the order Siluriformes products), §7381.196 (for poultry products), and §7590.910 (for egg products).", "3 Types of Equivalence Determinations There are four (4) types of equivalence determinations: (1) Initial Equivalence, (2) Ongoing Equivalence Verification, (3) Reinstatement of Equivalence, and (4) Individual Sanitary Measure. How to Start the Equivalence Process Countries wishing to export meat, poultry, or egg products to the US for the first time are to have their CCA contact FSIS' Office of International Coordination (OIC) by submitting a formal written to request an initial equivalence determination. In response to a country's request, FSIS will provide the country a packet of information that includes guidance and a Self-Reporting Tool (SRT). The SRT is a questionnaire that provides an organized means for the country's government to demonstrate that its inspection system achieves an equivalent level of protection as applied domestically in the US. The SRT is arranged into six components: \u2022Explanation About the Type of Equivalence Determination Types of Equivalence Determinations \u2022For countries seeking to export meat, poultry, or egg products to the US for the first time \u2022FSIS evaluates a country's food safety inspection system to make an initial equivalence determination before the country can export products to the US. \u2022Rulemaking is only required for initial equivalence determinations. (1) Initial Equivalence \u2022For countries that have an equivalence determination and are exporting meat, poultry, or egg products to the US \u2022Countries are to maintain communication with the US concerning updates to their food safety inspection system. (2) Ongoing Equivalence Verification \u2022For countries that FSIS has determined to have an equivalent food safety inspection system and stopped exporting to the US for an extended period of time \u2022FSIS will reassess the food safety inspection system before the country can export products to the US again. (3) Reinstatement of Equivalence \u2022For countries that have an equivalence determination and want to change a procedure in their food safety inspection system \u2022FSIS will assess the new procedure before the country can implement the procedure for products it exports to the US. (4) Individual Sanitary Measure", "4.1. Government Oversight (e.g., Organization and Administration) 2. Government Statutory Authority and Food Safety and Other Consumer Protection Regulations (e.g., Inspection System Operation, Product Standards and Labeling, and Humane Handling) 3. Government Sanitation 4. Government Hazard Analysis and Critical Control Point (HACCP) System 5. Government Chemical Residues Testing Programs 6. Government Microbiological Testing Programs NOTE:

Please refer to the Self-Reporting Tool (SRT) for additional information on how a country should categorize its food safety inspection system and respond to the SRT. Countries wishing to (1) reinstate previous equivalence determinations to start exporting meat, poultry, or egg products to the US again, or (2) change a procedure (sanitary measure) that the US has previously determined to be equivalent in their food safety inspection system are to submit a formal written request to OIC. A possible reason for a country to request a reinstatement of equivalence determination includes the lifting of a trade ban after an extended period of time due to a change in animal disease status allowing the export of certain animal products to the US. An example of an individual sanitary measure equivalence determination request is when a country wants to change its postmortem inspection procedures for livestock from traditional (hands-on) inspection to a visual assessment. NOTE: Reinstatement and individual sanitary measure equivalence determination requests are only applicable to countries that have received an initial equivalence determination of their food safety inspection system for meat, poultry, or egg products. Written requests must clarify the type of equivalence determination (for example, initial, reinstatement, or individual sanitary measure), as well as the commodity the request is for. Some examples of requests include: reinstatement of equivalence for raw beef, or initial equivalence for heat-treated and thermally processed poultry. Please submit all written equivalence requests to: United States Department of Agriculture Food Safety and Inspection Service Office of International Coordination 1400 Independence Avenue, SW Room 3143, South Building Washington, DC 20250 Phone: (202) 708-9543 Fax: (202) 690-3856", "5 E-mail: InternationalCoordination@fsis.usda.gov Letters can be transmitted by e-mail (preferred), mail, or fax.

**Initial Equivalence Process**

An initial equivalence determination by FSIS of a country's meat, poultry, or egg products food safety inspection system is a prerequisite for trade with the US. The FMIA, PPIA, and EPIA require FSIS to establish the equivalence of a country's food safety inspection system before accepting meat, poultry, or egg products from the exporting country for sale in US commerce. To establish equivalence, FSIS assesses a country's food safety inspection system through the country's responses to the SRT, including a review of supporting documentation (for example, food safety legislation, policies, and annexes) that the country provides to support its answers in the SRT, and through an on-site verification audit. The following six (6) steps briefly outline the initial equivalence process for a country wishing to secure an initial equivalence determination to export meat, poultry, or egg products to the US for the first time.

**Step 1 \u2013 Country Submits Written Request to FSIS**

Any country can request eligibility to export meat, poultry, or egg products to the US. The eligibility process begins with a formal written request submitted to FSIS's OIC. For more information on submitting a formal written request, please refer to subsection "\u201cHow to Start the Equivalence Process,\u201d under the "\u201cTypes of Equivalence Determinations\u201d section.

**Step 2 \u2013 Document Submission Through a Self-Reporting Tool**

In response to a country's request for equivalence, FSIS will provide the country a packet of information that includes guidance and the SRT. NOTE: Please refer to the Self-Reporting Tool (SRT) for additional information on how a country should categorize their food safety inspection system and respond to the SRT.

**Initial Equivalence Process**

1. Country Submits Written Request to FSIS
2. Document Submission Through Self-Reporting Tool
3. Document Review
4. On-site Verification Audit
5. Public Notification-Proposed Rule in Federal Register
6. Final Determination of Equivalence-Final Rule in Federal Register;

"6 A country can submit a

complete SRT by mail, electronic mail, or through FSIS\u2019s Public Health Inspection System (PHIS). PHIS is FSIS\u2019s web-based database that countries can access to complete an SRT and upload supporting documentation. The benefits of using PHIS to submit the information include an expedited SRT review, transparency, and security. To ensure an expedited review of a submitted SRT, particularly an SRT submitted in PHIS, FSIS encourages countries to submit SRT responses and supporting documentation in English. Countries are to contact FSIS\u2019s OIC for: \u2022 Questions and requests for technical assistance; \u2022 To submit a completed SRT and referenced supporting documentation in paper or electronically in Microsoft Word for FSIS\u2019s review ; or \u2022 To notify FSIS that an SRT has been submitted through PHIS.

NOTE: Please refer to FSIS\u2019s guide on Steps to Obtain Level 2 eAuthentication Credentials and PHIS Access for additional information on how to get access to PHIS. Please also refer to FSIS\u2019s presentation on How to Complete and Submit the SRT Using PHIS for additional information on how to complete and submit an SRT through FSIS\u2019s PHIS. Step 3

\u2013 Document Review After FSIS receives an SRT with all referenced supporting documentation, FSIS reviews the information to determine whether the country\u2019s documented food safety inspection system appears equivalent. If FSIS needs further information or clarification, OIC will advise the country\u2019s CCA of data, programs, or other information that the CCA needs to provide FSIS. If a country submits SRT responses with supporting documentation in a language other than English, FSIS will: 1. Send the documentation for translation into English, and place translated English responses into the SRT in PHIS. This provides the CCA the opportunity to verify the accuracy of the English-translated SRT responses and documents. 2. FSIS, using food safety objective-based criteria, will then review the SRT responses and supporting documentation to determine whether the country\u2019s documented food safety inspection system appears equivalent. 3. After FSIS completes its review, FSIS will send any questions requiring clarification to the CCA, or inform the CCA that its documented food safety inspection appears equivalent and advise on next steps. Key Point FSIS encourages countries to submit SRT responses and supporting documentation in English through PHIS to expedite the review process."

"7 IMPORTANT: Submitting SRT answers and documents in languages other than English will significantly delay FSIS\u2019s review process of the SRT. The translation process may take several months. To facilitate an efficient review of an SRT and supporting documentation, particularly an SRT submitted in PHIS, FSIS strongly encourages that countries submit their SRT responses and supporting documentation in English. NOTE: FSIS will accept SRT responses and supporting documentation submitted in any of the three (3) official languages of the WTO: English, French, or Spanish. Step 4 \u2013 On-Site Verification Audit An on-site verification audit is an audit of the country\u2019s food safety inspection system with the goal of verifying, through objective evidence, that the country\u2019s inspection system has an equivalent level of public health protection as applied domestically in the US. If FSIS determines that a country\u2019s food safety inspection system is tentatively equivalent based on the SRT document review process, OIC will work with the country\u2019s CCA to arrange an on-site verification audit of the country\u2019s food safety inspection system. Initial equivalence audits are conducted by FSIS International Auditors. The audit scope includes visual observations of all aspects of the country\u2019s food safety inspection system and may include the following: \u2022 Review of the country\u2019s laws, regulations, directives, notices, and other program implementation

documents; \u2022 Review of records of potential exporting establishments\u2019 operations, inspection results, and enforcement activities; \u2022 Review of the government chemical residue testing program; \u2022 Review of government microbiological testing programs; \u2022 Review of third party audit reports; and \u2022 Review of other US import requirements, such as pathogen reduction and HACCP system programs. During the on-site audit, International Auditors verify that the CCA implements, monitors, and verifies all of the procedures in the country\u2019s food safety inspection system. Typically, International Auditors will need to visit multiple sites that may include the following: \u2022 Central, regional, and local government offices; \u2022 Potential exporting establishments (slaughter and processing establishments) and warehouses (including cold storage); and \u2022 Laboratories." , "8 After the on-site audit, FSIS sends a draft audit report to the country applying for equivalence for the country\u2019s review and comment. FSIS then takes the country\u2019s comments into account and generates the final audit report. Step 5 \u2013 Public Notification - Proposed Rule in a Federal Register Based on the outcome of FSIS\u2019s SRT and supporting documentation review and the onsite audit, FSIS initiates rulemaking to propose that the country be listed in the CFR as eligible to export meat, poultry, or egg products to the US. To initiate rulemaking, the country will need to provide 5 years of projected economic analysis information. Upon publication, the public can submit comments (generally up to 60 days after publication) to FSIS about the proposed rule. Step 6 \u2013 Final Determination of Equivalence - Final Rule in Federal Register FSIS analyzes any received comments and publishes a final rule to list the country in the CFR as eligible to export meat, poultry, or egg products to the US. FSIS sends the country a letter notifying it of the published rule. The letter includes instructions about exporting meat, poultry, or egg products to the US. After the rule becomes effective, the country then certifies establishments as being eligible to export meat, poultry, or egg products to the US. After a country has compiled a list of eligible certified establishments, the country sends the completed list to OIC. A certified establishment is an establishment that the CCA determines as meeting US requirements and, therefore, eligible to export meat, poultry, or egg products to the US. NOTE: Equivalent countries are required to notify FSIS when there are changes in the eligibility of certified establishments, and must confirm with FSIS at least annually (by May 18th), after FSIS determines the country\u2019s food safety inspection system to be equivalent, all certified establishments eligible to export to the US. Additionally, countries are to submit to OIC a sample of the health certificate they propose to use for exported meat, poultry, or egg product shipments to the US. Each eligible country\u2019s CCA is responsible for the certification of shipments of meat, poultry, or egg products to the US. Please refer to Title 9 CFR \u00a7327.4 (for meat), \u00a7557.4 (for fish of the order Siluriformes products), \u00a7381.197 (for poultry), and \u00a7590.915 (for egg products). Please see FSIS Directive 9770.1, Determining the Initial Equivalence of Foreign Food Safety Systems, for additional information on how FSIS personnel make initial equivalence determinations. Animal Health Considerations It is important to note that FSIS only determines whether a country\u2019s meat, poultry, or egg products food safety inspection system is equivalent. Countries should be aware that animal diseases are regulated by the USDA\u2019s Animal and Plant Health Inspection", "9 Document Reviews On-Site Audits Point-of-Entry Reinspection Service (APHIS) (Title 9 CFR Parts 92 through 95), and a country\u2019s animal disease status can impact what products the country can export to the

US. For a list of USDA recognized animal health status of countries, please visit APHIS\2019s Animal Disease Status webpage ([https://www.aphis.usda.gov/aphis/ourfocus/animalhealth/animal-andanimal-product-import-information/ct\\_animal\\_disease\\_status](https://www.aphis.usda.gov/aphis/ourfocus/animalhealth/animal-andanimal-product-import-information/ct_animal_disease_status)). FSIS recommends that countries work with both FSIS and APHIS to address each Agency\2019s eligibility requirements to successfully export meat, poultry, or egg products to the US. If countries have questions or require further information related to imports of animal products or by-products, please contact APHIS\2019s National Center for Import and Export at: USDA, Animal and Plant Health Inspection Service (APHIS) Veterinary Services (VS) National Center for Import and Export 4700 River Road, Riverdale, MD 20737 Phone: (301) 851-3300, option 1 E-mail:

AskNIES.Products@aphis.usda.gov Ongoing Equivalence Verification Determination Process  
FSIS will continuously evaluate and verify the equivalency of an exporting country\2019s food safety inspection system through a three (3) part process: (1) document reviews, (2) on-site audits, and (3) point-of-entry reinspection of meat, poultry, and egg products. Part 1 \2013 Document Reviews Countries are to submit the following for review at least annually by May 18th: 1. Either (1) updated SRT responses, or (2) communicate to FSIS that the CCA has verified its SRT responses, as recorded in PHIS (i.e., by reviewing the SRT electronically in PHIS) or by mailed hard copy of the version of SRT responses FSIS has entered for the CCA, are accurate and complete. 2. An up-to-date list of all certified establishments eligible to export meat, poultry, or egg products the US. 3. An updated government residue control program, including the previous year\2019s residue test results and reactions to residue findings.", "10 4. Updated government microbiological sampling and testing programs, including the previous year\2019s test results and reactions to: (A) indicator organism results for intestinal or fecal contamination; (B) Salmonella and Campylobacter results for raw meat and poultry products; (C) Listeria monocytogenes, Salmonella, or other pathogens of public health concern in ready-to-eat (RTE) meat and poultry products and all lots of pasteurized egg products; and (D) STEC in raw beef products. Part 2 \2013 On-Site Audits FSIS will periodically conduct an on-site audit of every eligible country\2019s food safety inspection system. These audits will be performed by FSIS International Auditors and are similar to the on-site verification audits that FSIS does as part of the initial equivalence process. If a country has implemented any new individual sanitary measures since the previous audit, International Auditors will verify that the CCA is implementing the procedures as described in the submitted documentation for the individual sanitary measure that FSIS found equivalent. In addition, if a country has received multiple point-of-entry reinspection violations, the International Auditors may need to visit those certified establishments with the violations during the audit to determine whether there is a breakdown in the implementation of the country\2019s food safety inspection system. Please refer to Part 3 below for more information on point-of-entry reinspection. In addition, please refer to Step 4 subsection under the \201cInitial Equivalence Process\201d section for additional information about on-site audits performed by International Auditors. Part 3 \2013 Point-of-Entry Reinspection All imported shipments of meat, poultry, and egg products that enter the US are presented to FSIS for reinspection. FSIS has import inspection facilities located across the US at major ocean ports and land border crossings. At these import inspection facilities, FSIS checks every shipment for eligibility, certification, transportation damage, and labeling. The purpose of point-of-entry reinspection is to monitor the effectiveness of an

eligible exporting country's food safety inspection system, not to assess the performance of an individual certified establishment. In addition to point-of-entry shipment reinspection, FSIS performs more detailed, random reinspection activities on select lots within received shipments of meat, poultry, and egg products. These reinspection activities may include physical product examinations, condition-of-container reinspection, and laboratory sampling. Imported meat, poultry, and egg products determined to meet FSIS import requirements are stamped as "Inspected and Passed," and the products are released into US commerce. Non-compliant products are marked as "Refused Entry," and FSIS notifies the Importer of Record that the products are prohibited from entering US commerce."<sup>11</sup> Please see FSIS Directive 9780.1, Verifying the Ongoing Equivalence of Foreign Food Safety Systems, for additional information on how FSIS personnel verify the ongoing equivalence of foreign countries' food safety inspection systems. Please see FSIS Directive 9900.2, Import Reinspection of Meat, Poultry, and Egg Products, for additional information on FSIS's reinspection procedures.

Reinstatement of Equivalence Process A reinstatement of equivalence process is undertaken when a country wants to start exporting meat, poultry, or egg products again to the US. A country requests a reinstatement of equivalence determination for a specific commodity (for example, raw beef) after a long period of trade inactivity. The trade inactivity is typically due to the implementation of a trade ban preventing the exportation of certain animal products to the US due to a country's animal disease status. A reinstatement of equivalence process follows the same process as the initial equivalence process, except that the country may be subjected to a verification audit, and will not be subjected to the rulemaking steps. The rulemaking steps are not applicable for a reinstatement of equivalence determination because the country's food safety inspection system has already been determined to be equivalent. The following five (5) steps briefly outline the process for reinstating equivalence: Please refer to Steps 1 through 4 under the "Initial Equivalence Process" subsections for additional information. After FSIS completes its document review and, as needed, an on-site verification audit, OIC will notify the country of FSIS's decision through a formal written letter. The letter will discuss FSIS's basis for its decision to reinstate equivalence. If FSIS does not perform an audit as part of the reinstatement of equivalence process, then FSIS will verify the reinstated process during the next scheduled audit. Please see FSIS Directive 9770.1, Determining the Initial Equivalence of Foreign Food Safety Systems, for additional information on how FSIS personnel make reinstatement of equivalence determinations.

Reinstatement of Equivalence Process 1. Country submits written request to FSIS 2. Document submission through Self-Reporting Tool 3. Document review 4. On-site verification audit (may or may not be needed) 5. FSIS notifies country of equivalence determination through a formal written letter (no rulemaking is necessary)<sup>12</sup>

Individual Sanitary Measure Equivalence Process Eligible countries currently exporting meat, poultry, or egg products to the US request an individual sanitary measure when they want to change a procedure in their food safety inspection system. An eligible country is to request an individual sanitary measure equivalence determination before the country implements the new procedure on products destined for export to the US. Countries are to submit a formal written request for an individual sanitary measure to FSIS's OIC. If a country does not notify FSIS of changes in its food safety procedures, a possible disruption of trade could result. FSIS will evaluate a request for an individual sanitary measure equivalence

determination to ensure that the new procedure: \u2022 Is equivalent to FSIS\u2019s relevant food safety regulatory objective-based criteria, and \u2022 Achieves an appropriate level of protection from identified food safety hazards. There are two (2) reasons an eligible country requests an individual sanitary measure equivalence determination. 1. The country wants to make a change to a procedure in its food safety inspection system that FSIS previously determined was equivalent. 2. FSIS has updated its US domestic food safety procedures or requirements and identified that the procedures or requirements affect previous equivalence determinations for specific eligible countries. If FSIS determines that eligible countries may be affected by a change in US domestic procedures or requirements, OIC provides notice through the WTO and directly communicates to all countries exporting meat, poultry, or egg products to the US. After FSIS publishes the procedures or requirements as part of final rulemaking through a Federal Register Notice, they become an import requirement. The following five (5) steps briefly summarize the individual sanitary measure equivalence process: Please refer to Steps 1 through 3 under the \u201cInitial Equivalence Process\u201d subsections for additional information.

**Individual Sanitary Measure Equivalence Process**

1. Country submits written request to FSIS
2. Document submission through Self-Reporting Tool
3. Document review
4. FSIS notifies country of its individual sanitary measure equivalence determination through a formal written letter.
5. Countries that request an individual sanitary measure will need to update their SRT and submit supporting documentation to FSIS for review. The submitted documentation should demonstrate that the measure provides an equivalent level of public health protection. After FSIS completes its review, OIC will notify the country of FSIS\u2019s decision through a formal written letter. The letter will discuss FSIS\u2019s basis for its decision to either accept or reject the proposed individual sanitary measure. If FSIS accepts the individual sanitary measure, FSIS will verify the application of the individual sanitary measure during the next scheduled on-site verification audit.

**Whom to Contact for Questions or Request Additional Information**

Countries are to contact FSIS\u2019s OIC for:

1. All questions and requests for technical assistance,
2. To submit formal equivalence requests,
3. To submit a paper copy of an SRT and supporting documentation for review, or
4. To notify FSIS that an SRT was submitted in PHIS.

OIC can be contacted at: United States Department of Agriculture Food Safety and Inspection Service Office of International Coordination 1400 Independence Avenue, SW Room 3143, South Building Washington, DC 20250 Phone: (202) 708-9543 Fax: (202) 690-3856 E-mail: InternationalCoordination@fsis.usda.gov

**Helpful Equivalence Resources**

The following additional FSIS equivalence resources are available to help countries better understand the equivalence process, how to complete the SRT, obtain level 2 eAuthentication credentials, and access PHIS to view and complete an SRT.

- \u2022 FSIS\u2019s Equivalence Webpage
- \u2022 FSIS\u2019s presentation on The FSIS Equivalence Process
- \u2022 2019 Self-Reporting Tool
- \u2022 Steps to Obtain Level 2 eAuthentication Credentials and PHIS Access
- \u2022 FSIS\u2019s presentation on How to Complete and Submit the SRT Using the PHIS

The standard does not require the States operate their MPI programs in a manner that is the same as or identical to FSIS\u2019s inspection program, nor does it prohibit the State MPI programs from establishing safeguards they believe to be more effective than those employed by FSIS. KEY DEFINITION AND STATE MPI PROGRAM REQUIREMENT \u201cAt Least Equal To\u201d Page 4", "I. PURPOSE This guideline provides information to State Cooperative Inspection programs on the criteria that the Food Safety and Inspection Service (FSIS) uses to determine each year whether State Meat and Poultry Inspection (MPI) programs are operating verifiably in accordance with requirements that are \u201cat least equal to\u201d the Federal inspection requirements. The guideline contains information that State MPI programs need to establish and maintain such programs. II. BACKGROUND The Federal Meat Inspection Act (FMIA) (21 U.S.C. 661) and the Poultry Products Inspection Act (PPIA) (21 U.S.C. 454) authorize FSIS to cooperate with State agencies in developing and administering their own Meat and Poultry Inspection (MPI) programs. Individual State MPI programs are required to operate under authorities that are \u201cat least equal to\u201d the provisions for ante-mortem and post-mortem inspection, reinspection, sanitation, recordkeeping, and enforcement in the FMIA and PPIA and implementing regulations. State MPI programs are also expected to ensure livestock are treated humanely by assuring the methods of handling livestock are \u201cat least equal to\u201d those outlined in the Humane

Methods of Slaughter Act of 1978 (HMSA)(7 U.S.C. 1901-906). The FMIA (21 U.S.C. 661(b)) and the PPIA (21 U.S.C. 454 (b)) authorize FSIS to cooperate with a single State agency and subordinate governmental unit primarily responsible for the coordination of a State MPI program. In matters concerning the State MPI program, FSIS will communicate and coordinate with designated State employees assigned to the single State agency identified by the State as responsible for ensuring that all applicable inspection and compliance activities outlined in these guidelines comply with specified laws, regulations and policies. The activities include those conducted by State or contract laboratories, public health departments, law enforcement agencies, State human resource departments, budget departments and other State regulatory agencies. This guideline replaces the previous version, issued July 2008. FSIS updated the guideline to consolidate components, add new components and resource information, and to revise tables. The most notable changes are as follows: The date for the States\u2019 annual self-assessment submission has changed from November 15th to November 1st of each year. Component 1 - Statutory Authority and Food Safety Regulations has a new table titled \u201cStatutory Side-by-Side Comparison Table\u201d Component 2 - Inspection includes: \u2022 Former Component 6 \u2013 Non- Food Safety Consumer Protection is added in its entirety; \u2022 The Quarterly New Issuance Review process is a new section added to this component; and \u2022 The guideline titled, \u201cAt least equal to data system requirements for State Cooperative Meat and Poultry Inspection (MPI) programs electing not to use FSIS\u2019s Public Health Information System (PHIS)\u201d published in January 2015 is added at the end of Component 2. Component 3 \u2013 Sampling Programs (formerly known as \u201cProduct Sampling\u201d) has been retitled. SIGNIFICANT CHANGES Page 5", "III. ANNUAL SELF-ASSESSMENT FSIS expects the State MPI programs to submit their annual self-assessment documents to FSIS\u2019s FederalState Audit Branch (FSAB) on or before November 1st of each year. Each State MPI program should start its annual self-assessment with a review of the prior-year selfassessment. Each component of the annual selfassessment should include a written narrative statement and documentation demonstrating the program continuously meets the criteria to be \u201cat least equal to\u201d the Federal program. The self-assessment should identify any program changes in the previous 12 months and include documentation which will support the State\u2019s ability to maintain its program for the next 12 months. State MPI programs should also submit sufficient documentation to demonstrate the State MPI program has stayed current with FSIS statutes, regulations, applicable FSIS Directives and Notices, and has implemented any changes necessary to maintain its \u201cat least equal to\u201d status. The annual self-assessment submission should also include one or more narratives describing internal controls used by the State MPI program that: \u2022 Provide assurances that internal controls can measure the effectiveness of the program under the \u201cat least equal to\u201d criteria; \u2022 Demonstrate how nonconformances will be addressed by corrective actions; and \u2022 Demonstrate how the State MPI program will be maintained throughout the next 12 months. These internal controls should provide an objective assessment of the State MPI program\u2019s operations and processes to determine whether: \u2022 Financial and operating information is accurate and reliable; \u2022 Operational risks are appropriately identified and managed; \u2022 Applicable regulations and internal policies and procedures are followed; and \u2022 The \u201cat least equal to\u201d standard is maintained. Component 6 \u2013 Compliance (formerly known as \u201cComponent 7 \u2013

Compliance\u201d) has been retitled and includes a new table titled \u201cSummary of Statutory Authority per Business Type.\u201d Component 7 \u2013 Laboratory Methods and Quality Assurance Program is a new component for laboratory methods and quality assurance criteria. This information was previously published in June 2014 as a separate guideline titled \u201cAt Least Equal To Compliance Guideline for State Meat and Poultry Inspection (MPI) Programs for Laboratory Methods\u201d and has been updated and added as a component. The following Tables have been updated to better reflect the information needed by FSIS in the evaluation of State MPI program operations: Component 3 \u2013 State MPI Program Sampling Activity Table. Component 4 \u2013 State MPI Program Establishment Count and the State MPI Program Employee Primary Roles. Component 6 \u2013 Compliance Activity Report. Additional Resources is a new section added at the end of the guideline to provide State MPI program Directors with reference material that may be needed to perform business processes related to budget submissions, training and Federal resource information, cooperation between State and Federal Compliance programs, and information on internal controls. The section also includes a Reference Table of Related FSIS Policy Documents, which is a reference guide to FSIS policy documents relevant to the implementation of the nine program components. Page 6", "Ultimately, State MPI programs need to operate in a manner that protects the health and welfare of consumers within their State by ensuring the meat and poultry products distributed by the program establishments are wholesome, not adulterated, and properly marked, labeled, and packaged. More specifically, the annual self-assessment should also address each of the following nine program components so as to demonstrate the State\u2019s MPI program is administered in a manner that is \u201cat least equal to\u201d the Federal inspection requirements and describe how it will maintain this status for the following 12 months. FSIS Directive 5720.3, Methodology for Performing Scheduled and Targeted Reviews of State Meat and Poultry Inspection Programs, provides the FSIS review methodology and criteria for each component. For each of the first six (1-6) components, State MPI programs need to submit selfassessment documentation demonstrating the State MPI program is meeting the \u201cat least equal to\u201d Federal inspection requirements. Such documentation should include the attached Annual Certification \u2013 \u201cAt Least Equal To\u201d Meat and Poultry Inspection Program (Attachment 1, page 10) and a narrative describing any changes made in the State MPI program during the previous 12 months. For Component 2, State MPI programs that have elected not to use the FSIS Public Health Information System (PHIS), should refer to guidance information (Attachment 3, Component 1 Statutory Authority and Food Safety Regulations Component 2 Inspection Component 3 Sampling Programs Component 4 Staffing, Training, and Supervision Component 5 Humane Handling Component 6 Compliance Component 7 Laboratory Methods and Quality Assurance Program Component 8 Civil Rights Component 9 Financial Accountability The Nine Program Components Page 7", "page 38) titled, \u201cAt least equal to\u201d data system guidance for State Cooperative Meat and Poultry Inspection (MPI) programs electing not to use Public Health Information System (PHIS) can be found at the end of Component 2. State MPI program Directors are to submit the requested data system information with the annual self-assessment submission to FSAB for review. For Component 7, State MPI programs need to submit the following self-assessment documentation to FSIS, Office of Public Health Science (OPHS): \u2022 A list of current State laboratory and/or contract laboratory test methods and copies of new or revised methods

accompanied by a Laboratory Method Notification Form; and \u2022 A completed FSIS Form 5720-14, FSIS MPI Program Laboratory Quality Management System Checklist or use another easy to read format for each State or contract laboratory performing MPI-related analyses or their current ISO 17025 certificates of accreditation for each State and/or contract laboratory performing MPI-related analyses For Component 8, the State MPI programs are to complete and submit FSIS Form 1520-1, Civil Rights Compliance of State-Inspection Programs, or use another easy to read format to the FSIS Civil Rights Staff. Relative to Component 9, the State MPI programs should submit specified financial reports as requested throughout the fiscal year. Although deadlines for submitting certain financial reports may coincide with FSIS\u2019s self-assessment submission deadline of November 1. Financial Reviews and Analysis Section (FRAS) does not require the inclusion of these financial reports as part of the annual self-assessment submission for Component 9. Component 9 includes a list of supporting documentation the State agencies should have readily available for FSIS reviewers, upon request, prior to or during the on-site financial review. State MPI program Directors should submit the self-assessment for the various program components and any required or requested documents as follows:

**REVIEW** In addition to the annual self-assessment submission, State MPI programs are subject to an on-site review at a minimum frequency of once every three years to verify the accuracy and implementation of the self-assessment submissions. In the year that a State MPI program is scheduled for an on-site review, FSIS\u2019s annual determination of whether the program is \u201cat least equal to\u201d the Federal inspection program will be based on a review of the annual self-assessment submission and the on-site review. Please refer to FSIS Directive 5720.3, Methodology for Performing Scheduled and Targeted Reviews of State Meat and Poultry Inspection Programs, for the FSIS Review Methodology. The purpose of the on-site review is for FSIS to verify the State MPI program implements and maintains its inspection system in accordance with its annually submitted self-assessment, and to determine whether the State MPI program is \u201cat least equal to\u201d the Federal inspection program in its administration and enforcement of requirements. The FSIS review team will review the State MPI program\u2019s current annual self-assessment submission in advance so that they are able to begin the on-site review of the State MPI program with a thorough understanding of the State program\u2019s current self-assessment submission. FSIS will review a selected number of establishments within the State MPI program and examine and evaluate documentation at the central office to verify the State MPI program\u2019s implementation, oversight, and management controls. In October of each year, FSIS will announce the State MPI programs scheduled for an on-site review in the upcoming federal fiscal year. FSIS will send a written notification to State MPI programs at least 30 days before the start of the on-site review process. The on-site review will begin with a teleconference serving as the entrance meeting between FSIS and State MPI program officials. To facilitate FSIS\u2019s selection of establishments to review, State MPI program officials are to supply information from the last 12 months (12 months prior to review) to FSIS within 10 business days after the conclusion of the entrance meeting. The information is to include the following: \u2022 A current list of establishments and their operating schedules (please omit ID warehouses and establishments which slaughter or process only non-amenable species), supervisory boundaries, program updates, and HACCP process categories for all establishments with the 5 highest producers for each category identified. \u2022 Positive Shiga toxin-producing E. coli (STEC) results \u2022 Positive Listeria monocytogenes (Lm) or Salmonella results in RTE products \u2022 Failures of Salmonella and Campylobacter Performance Standards for raw products \u2022 Enforcement actions taken \u2022 Recalls conducted and associated documentation", "\u2022 Establishments that sustained structural damage in production areas due to natural disasters \u2022 Establishments that the State MPI program reviewed, e.g., FSAs, supervisory reviews, internal reviews, management control audits At least one week before the scheduled on-site review, FSIS will notify the State MPI program of the establishments chosen for the on-site review. Should the State MPI program officials ask FSIS to omit a chosen State establishment from its review, they will need to provide written justification for their request (e.g., the establishment is closed the day of the review, the establishment is a seasonal operator). FSIS travels to the chosen State establishment and follows the on-site review protocol. If a chosen State establishment decides not to operate after the on-site review process begins, FSIS selects an alternate State establishment to visit. An electronic draft report of individual establishment findings will be provided to the State MPI program officials by the next business day. At the end of each establishment review, after a short correlation with FSIS, the State MPI program

personnel will lead an exit meeting with State establishment management. Within 10 working days of completing the on-site review, FSAB will schedule a teleconference exit meeting with State MPI program officials. Before the teleconference exit meeting, FSAB will provide a summary report of all findings to the State MPI program officials. The types of findings detailed in the aforementioned FSAB summary report that requires corrective actions will include: \u2022 Processes that are not operating or functioning in the manner intended as detailed in the State\u2019s annual self-assessment or that are not included in the self-assessment submission; \u2022 Processes that are ineffective; and \u2022 Regulatory noncompliances. The State MPI program has 10 working days after the teleconference to present an action plan designed to address all findings that require corrective actions. The State MPI program is to identify any underlying causes for findings that require corrective actions. Corrective actions may include the implementation of preventive measures e.g., targeted staff training, increased supervisory oversight, where applicable. If the State MPI program is unable to identify underlying causes for certain findings they are to share and explain the method they used in their attempts to identify the underlying causes and the results of the associated evaluation conducted to draw the conclusion. They are to also justify why they believe the corrective actions identified in the action plan for such findings are adequate. After receiving documentation demonstrating implementation of the action plan, FSAB will assess the plan and determine if actions taken are sufficient. If the action plan is adequate FSAB will issue a determination Page 12", "memorandum and Interim Annual Comprehensive Review and Determination Report to the State MPI program Director. FSIS may request clarification of specific items regarding the State MPI program\u2019s implementation of its action plan, and in certain cases, may perform a targeted on-site review before the issuance of a determination memorandum. A targeted on-site review conducted prior to the issuance of a determination memorandum is an in-depth evaluation of the State MPI program\u2019s implementation of its action plan. FSIS uses the targeted review to verify resolution of any public health concerns and compliance with the \u201cat least equal to\u201d criteria. The Annual Comprehensive Review and Determination Report will summarize the results of the State\u2019s self-assessment submission and on-site review of the State MPI program (including the results of the targeted on-site review, if applicable). The report will include the FSIS review team\u2019s final \u201cat least equal to\u201d determination supported by individual component determinations.

V. DETERMINATION PROCESS

FSIS makes a determination after evaluating the State\u2019s annual self-assessment and the results of the on-site review, as applicable. The definitions for the three FSIS determinations on the status of the State MPI program are:

1. \u201cAt Least Equal To\u201d The State MPI program has adopted laws, regulations, and programs, and implements them in a manner that is \u201cat least equal to\u201d FSIS\u2019s Federal inspection program for all review components.
2. \u201cAt Least Equal To,\u201d with Provisions\u2014FSIS makes a provisional determination of the State MPI program\u2019s \u201cat least equal to,\u201d status provided the program takes additional action to resolve review findings.
3. Not \u201cAt Least Equal To\u201d The State MPI program has not adopted laws, regulations, or programs, or does not implement them in a manner that is \u201cat least equal to\u201d FSIS\u2019s Federal inspection program for one or more of the review components. At the conclusion of each annual self-assessment review, FSIS decides whether the State MPI program is or is not meeting the \u201cat least equal

to\ud requirements. If the State MPI program is not scheduled for an on-site review during the current fiscal year, FSIS makes an annual determination based only on the results of the self-assessment review. If the State MPI program is scheduled for an on-site review during the current fiscal year, FSIS bases the annual determination on the results of the self-assessment and the on-site review. If the determination of the self-assessment, or self-assessment and the on-site review, if applicable, is that the State program meets the \udat least equal to\ud standard, FSIS promptly gives the State program officials written notification of that Page 13", "fact. If additional clarification is needed for a determination, FSIS requests supplemental information from the State MPI program and issues an Interim Annual Comprehensive Review and Determination Report. When an analysis of all findings, clarifications, and corrective actions from the selfassessment or on-site review indicates a State MPI program cannot support an \udat least equal to\ud determination, FSIS recommends to the Secretary of Agriculture that the State be designated for Federal inspection.<sup>1</sup> If a State cannot immediately implement an action plan but is committed to making the corrections and has the resources to support the changes, FSIS defers designation instead of making a final determination that the State program is not \udat least equal to\ud FSIS\ud 19s Federal inspection program. Before the Secretary initiates the Federal designation process that results in State establishments being subject to the Federal inspection program, FSIS and the State agency confer on the State MPI program\ud 19s deficiencies. If the State MPI program is unable to meet the \udat least equal to\ud requirements or if its responsible officials are unwilling to do so, the Secretary of Agriculture notifies the Governor of the State that the State does not have an \udat least equal to\ud MPI program and is not in compliance with the cooperative agreement between FSIS and the State, and is subject to the Federal designation of its MPI program. If deficiencies are not resolved, the Secretary will designate the State MPI program for Federal meat and poultry inspection and publish a notice of the designation in the Federal Register. Upon the expiration of thirty days after the publication of the Federal Register notice the State-inspected establishments will become subject to Federal inspection.

VI. APPEAL PROCESS State officials have the right to appeal any program status determination made by FSIS. The appeal process follows the Office of Investigation, Enforcement and Audit\ud 19s (OIEA) chain of command. The chain of command ensures that Agency employees most familiar with the facts of the appeal will perform the initial evaluation of the appeal. The Appeal process gives State officials the right to appeal to the next highest level if not satisfied with the outcome. The OIEA chain of command is: 1) FSIS employee who made the finding (e.g., FSAB Program Auditor); 2) FSAB Team Lead; 3) FSAB Chief; 4) Management Controls and Audit Division (MCAD) Director; 5) OIEA Deputy Assistant Administrator; 1 Directive 5710.1, Designation of States for Federal Meat or Poultry Inspection, outlines the procedures for designation of States for Federal meat or poultry inspection. Page 14", "6)OIEA Assistant Administrator; and 7)FSIS Administrator.

VII.FSIS REPORTS The State MPI program officials are notified in writing when FSIS makes a determination after analysis of the self-assessment and on-site review, as applicable. An individual end-of-year report is sent to each State MPI program summarizing program findings. Additionally, each year FSIS publishes on its Web site an overall end-of-year summary report of the findings and final determinations for all State MPI programs at <http://www.fsis.usda.gov/wps/portal/fsis/topics/inspection/state-inspectionprograms/state-inspection-and-cooperative-agreements/reviews-of-state->

programs VIII.NINE PROGRAM COMPONENTS Criteria for \u201cat least equal to\u201d determination State MPI programs need to have meat and poultry inspection laws and regulations that impose mandatory ante-mortem and post-mortem inspection, reinspection, sanitation requirements, recordkeeping requirements, and enforcement authorities \u201cat least equal to\u201d those prescribed by the FMIA<sup>2</sup> (21 U.S.C. 601, et seq.) and PPIA<sup>3</sup>(21 U.S.C. 451, et seq.). State MPI programs need to also enforce requirements that are \u201cat least equal to\u201d those imposed under the Humane Methods of Slaughter Act of 1978 (HMSA)<sup>4</sup> (7 U.S.C. 1901, et seq.). 2 The Federal Meat Inspection Act (21 U.S.C. 601, et seq.) governs the slaughter of livestock and the processing and distribution of meat products in the United States. Passed by Congress in March 1907, the FMIA authorizes the Secretary of Agriculture to set national standards for meat inspection. The FMIA was amended in the Wholesome Meat Act of 1967, granting the Secretary of Agriculture the authority to authorize each State to develop its own meat inspection program if their requirements are \u201cat least equal to\u201d Federal requirements. The amended FMIA assures uniformity in regulation of products shipped interstate, intrastate, and in foreign commerce. 3 The Poultry Products Inspection Act (21 U.S.C. 451, et seq.) governs the slaughtering, processing, and distribution of poultry products in the United States. Passed by Congress in August 1957, the PPIA authorizes the Secretary of Agriculture to make rules and regulations setting national standards for poultry inspection. The PPIA was amended in the Wholesome Poultry Products Act of 1968, granting the Secretary of Agriculture the authority to authorize each State to develop its own poultry inspection program if their requirements are \u201cat least equal to\u201d federal requirements. The amended PPIA assures uniformity in regulation of products shipped interstate, intrastate, and in foreign commerce. 4 The Humane Methods of Slaughter Act (7 U.S.C. 1901 et seq.) governs the humane treatment of animals at official establishments. Passed by Congress in 1978, the HMSA authorizes the Secretary of Agriculture to make rules and regulations setting national standards for livestock inspection. The HMSA prevents needless suffering of animals, Component 1: Statutory Authority and Food Safety Regulations Page 15 Component 1: Statutory Authority and Food Safety Regulations", "State MPI programs need to also be in compliance with Federal Civil Rights laws: \u2022 Title VI of the Civil Rights Act of 1964 [42 U.S.C. 200 (d)]; \u2022 Section 504 of the Rehabilitation Act of 1973, as Amended (29 U.S.C. 794); \u2022 Age Discrimination Act of 1990 (42 U.S.C. 12101, et seq.); \u2022 Applicable USDA Civil Rights regulations; \u2022 Financial Accountability requirements pursuant to the Uniform Administrative Requirements for Grants and Cooperative Agreements to State and Local Governments (7 Code of Federal Regulations (CFR) Part 3016), (previously known as the Common Rule); \u2022 The Uniform Administrative Requirements for Grants and Cooperative Agreements to State and Local Governments (7CFR Part 3016), (previously known as the Common Rule); and \u2022 FSIS Directive 3300.1, Rev. 2, Fiscal Guidelines for Cooperative Meat and Poultry Inspection Programs. To ensure States are in compliance with the statutory and regulatory requirements detailed above, State MPI programs need to: \u2022 Adopt by reference the FMIA, PPIA, and HMSA and implementing regulations; or impose State laws that meet the \u201cat least equal to\u201d requirements of the FMIA, PPIA, and HMSA, and explain in their submission to FSIS how those requirements provide a level of protection that is \u201cat least equal to\u201d that which is imposed by the FMIA, PPIA, HMSA and implementing regulations FSIS allows time for the State\u2019s rulemaking process when

necessary, because there are States that have legislatures that do not always meet on an annual basis. The State MPI program needs to ensure there are measures in place to verify compliance and take enforcement actions for non-compliance findings until the final rulemaking process has been completed. The State MPI program needs to have the authority to expedite the rulemaking process in a manner \u201cat least equal to\u201d that provided for in the Administrative Procedure Act, 5 U.S.C. \u00a7553. If a State MPI program has enacted its own comparable State statutes and regulations that are \u201cat least equal to\u201d those governing the Federal inspection requirements, it needs to ensure that the statutes and regulations establish requirements that State produces safer and better working conditions, brings about improvement of products and economies, and produces other benefits for producers, processors and consumers. Nothing in the HSSA shall be construed to prohibit, abridge, or in any other way hinder the religious freedom of any person or group. Page 16", "establishments maintain sanitary conditions and operate in a manner that includes evaluating hazards, taking steps to control hazards, and routinely verifying that product is safe, wholesome, not adulterated, and properly marked and labeled. States need to ensure that their statutes and regulations adequately address, in an \u201cat least equal to\u201d manner, mandatory ante-mortem and post-mortem inspection, reinspection, sanitation requirements, recordkeeping requirements, compliance provisions, and enforcement authorities to ensure that product is wholesome and not adulterated. In addition, State regulations need to address the humane treatment of animals at establishments under inspection. Outcome The expected outcome is a set of laws and regulations in place that, when objectively reviewed by FSIS, are determined to be \u201cat least equal to\u201d FSIS\u2019s Federal laws and regulations.

\u201cAt least equal to\u201d Requirements State MPI program officials need to stay current with applicable laws, administrative rules, FSIS regulations, FSIS directives and notices, and any other policies, and be able to explain how their State programs are \u201cat least equal to\u201d FSIS\u2019s Federal inspection program requirements. The State officials should include a narrative that describes any changes in the State laws and regulations over the past 12 months, and of any proposed changes that may affect their \u201cat least equal to\u201d status over the subsequent 12 months. Objective State MPI programs need to periodically review applicable State laws, regulations, FSIS Directives and Notices and other FSIS policies to ensure the State programs provide a level of protection that is \u201cat least equal to\u201d those imposed by FMIA, PPIA, HSSA and regulations in section 9 of the CFR.

Statutory Authority and Food Safety Regulations Methods and Procedures State MPI programs need to have methods to periodically evaluate changes to Federal laws and regulations for applicability to State MPI programs, and need to revise State MPI laws and regulations as necessary. The methods should, at a minimum, address the following critical aspects: \u2022 Procedures for periodic evaluation of changes to applicable laws and regulations; \u2022 State legislative procedures; \u2022 State emergency legislative procedures; Page 17", "\u2022 State rulemaking procedures; and \u2022 State emergency rulemaking procedures. Evidence of system application State MPI programs should provide evidence which demonstrates implementation of methods and procedures that are \u201cat least equal to\u201d those of FSIS\u2019s Federal inspection program. At a minimum, the State MPI program should submit:

\u2022 Documentation of periodic evaluations of current State laws, regulations and other policies; \u2022 The State laws and regulations applicable when species other than those

covered by the FMIA and PPIA are considered amenable under State laws; \u2022 Current copies or Web links to State laws, regulations, and other policies with specific cross-references to 9 CFR; \u2022 Current copies or Web links to State rulemaking and emergency rulemaking procedures; \u2022 Documentation of laws and regulations currently undergoing State rulemaking and emergency rulemaking processes which affect the State MPI program; \u2022 Documentation that verify State laws are \u201cat least equal to\u201d the provisions of the FMIA, PPIA, and HMA as specified in Attachment 2; and NOTE: The Statutory Side-by-Side Comparison Table (Attachment 2, page 19) has been provided as a tool for the State MPI programs to demonstrate comparable State statutes, laws, or regulations for each of the applicable FMIA, PPIA, and HMA provisions. \u2022 Legal documentation that State MPI programs have the authority to impose meat and poultry inspection laws and regulations with the same purposes as the Federal laws that govern FSIS\u2019s Federal inspection program.

Not applicable for \u201cat least equal to\u201d criteria Page 25", "Criteria for \u201cat least equal to\u201d Determination Each State MPI program need to submit a current narrative describing the State inspection system used to enforce all applicable laws, regulations, and FSIS policies. The State system should have the capability to correct any deviations from regulatory requirements that may affect its program\u2019s being \u201cat least equal to\u201d FSIS\u2019s Federal inspection program. State MPI programs need to submit any supporting documentation (preferably completed reports and documents) to demonstrate the State inspection system, as described in the narrative, has been implemented, is functioning as intended, and will ensure the State MPI program has the ability to remain \u201cat least equal to\u201d FSIS\u2019s Federal inspection program for the next 12 months. Inspection methods and procedures followed under a State MPI program must be \u201cat least equal to\u201d the FMIA, PPIA, HMA, the applicable regulations in 9 CFR 300 to end, and applicable policies issued for FSIS\u2019s Federal inspection program. At a minimum, the State inspection program should include the following criteria: \u2022 Ante-mortem A State MPI program is to examine and inspect all livestock and poultry before slaughter to determine whether animals are fit for slaughter and can be used for human food. A State MPI program should verify that establishments present all animals for ante-mortem inspection in accordance with the FMIA, PPIA, and 9 CFR, ensuring animals with abnormalities and signs that could otherwise indicate disease are removed from human edible food channels. \u2022 Post-mortem State Inspection Program Personnel (IPP) should examine and inspect carcasses in the slaughter process and post-mortem in State inspected establishments to determine whether carcasses and parts are wholesome and not adulterated and thus permitted to receive the State mark of inspection. Inspection of meat and poultry carcasses, including applicable parts, is conducted in a manner \u201cat least equal to\u201d FSIS\u2019s processes, as described in 9 CFR 311 and 381, Subpart K, respectively. \u2022 Sanitation A State MPI program should verify that establishments have developed, implemented, and maintained Sanitation Standard Operating Procedures (Sanitation SOPs) consistent with requirements in 9 CFR 416. \u2022 Food Safety Requirements A State MPI program should verify each State inspected

establishment\u2019s food safety system, including Hazard Analysis and Critical Control Point (HACCP) plans are consistent with requirements in 9 CFR 417. \u2022 Non-Food Safety Requirements A State MPI program should verify all products produced for distribution in intrastate commerce are wholesome, and properly labeled. State IPP need to perform the appropriate activities for verifying Component 2: Inspection Page 26", "compliance with applicable requirements to those in the FMIA, PPIA, and 9 CFR. These activities include verifying accuracy of State inspected establishment product formulation for labeling and product standard of identity requirements; observing preparation or processing procedures; reviewing establishment records; and performing a variety of in-plant measurements and calculations.

\u2022 Regulatory Enforcement A State MPI program should develop and apply administrative enforcement consistent with those in 9 CFR 500 (Rules of Practice) to ensure establishments are provided due process of law and bring noncompliant establishments back into compliance with the FMIA, PPIA, HMSA, and 9 CFR. \u2022 Exempt Facility Reviews A State MPI program should verify that all products produced in State exempt facilities (either in official State inspected establishments or a separate facility) comply with regulatory and statutory requirements for sanitation, adulteration, and labeling. \u2022 New Issuance Reviews A State MPI program should evaluate the applicability of new FSIS laws, regulations, FSIS Directives and Notices and any other policies, and ensure they are implemented, as appropriate. Outcome When objectively reviewed by FSIS, the State MPI program is determined to be \u201cat least equal to\u201d FSIS\u2019s Federal inspection program. A State MPI program has: \u2022 A series of standards and policies that define how State inspected establishments can operate to produce safe, wholesome, not adulterated and properly labeled and packaged products.

\u2022 A comprehensive State regulatory inspection system (e.g., Public Health Information System (PHIS)) that collects, consolidates, and analyzes data and enforces the meat and poultry regulations at State-inspected establishment. NOTE: State MPI program Directors that have elected not to use FSIS\u2019s PHIS can find guidance information titled, \u201cAt least equal to\u201d data system guidance for State Cooperative Meat and Poultry Inspection (MPI) Programs electing not to use Public Health Information System (PHIS) (Attachment 3, page 38). State MPI program Directors are to submit the requested data system information with the annual selfassessment submission to the FSAB for review. By August 1st of each year, FSIS will provide State MPI programs with guidance on the PHIS inspection tasks. \u2022 Assurances that State-inspected establishments can maintain food safety systems to reduce, eliminate, or prevent food hazards (i.e., any biological, chemical, or physical property that may cause a food to be unsafe for human consumption) Page 27", "\u2022 A system to carry out administrative actions when State inspected establishments are not meeting the provisions of \u201cat least equal to\u201d the FMIA, PPIA, HMSA, applicable State laws, and 9 CFR \u2022 A system to review exempt facilities to determine their compliance under the sanitation, adulteration, labeling, and other statutory and regulatory requirements \u2022 A system to evaluate the applicability of new FSIS policies and determine how to implement the policies in the State MPI program \u201cAt least equal to\u201d Requirements The State MPI program is required to maintain: \u2022 A Slaughter Inspection System; \u2022 A Food Safety Verification System; \u2022 A Non-Food Safety Verification System; \u2022 An Exempt Facility Review System; and \u2022 A New Issuance Review System. NOTE: State MPI program Directors need to submit the data integrity information for the data collected and maintained in their system in place of the

PHIS. The data integrity information should include: \u2022 The type of data maintained outside of PHIS (e.g., FSAs, custom exempt reviews, NOIEs); \u2022 How the data integrity is maintained (e.g., safeguards to restrict access, security tools); and \u2022 The State law or administrative rule that governs the security and integrity preservation of meat and poultry inspection program records. Slaughter Inspection System State MPI programs should maintain a slaughter inspection system that is able to verify whether State inspected establishments comply with requirements consistent with the FMIA, PPIA, and HMSCA. The slaughter inspection system should have a method for assigning tasks and documenting task results for slaughter inspection requirements at State inspected establishments. The slaughter inspection system needs to be able to capture the results of ante-mortem and post-mortem inspection activities (e.g., suspected animals, condemned carcasses and parts) including the capability to capture any regulatory noncompliance and regulatory control actions taken. State MPI program officials should create or adopt slaughter inspection policies and procedures for conducting ante-mortem and post-mortem inspection activities that ensure compliance with Federal and State laws and regulations. Page 28", "Objective To implement state inspection activities which ensure animals are suitable for slaughter; products are not adulterated, wholesome, properly labeled, marked, and packaged, and carcasses and parts are eligible for human consumption. Inspection Methods and Procedures State MPI programs should implement slaughter inspection methods and procedures \u201cat least equal to\u201d those of FSIS\u2019s Federal inspection program. The methods and procedures at a minimum should include: \u2022 Methods and procedures to inspect livestock and poultry before slaughter (antemortem inspection) and verify that animals offered for slaughter have received ante-mortem inspection \u2022 Procedures to follow when State IPP observe animals showing symptoms of disease or abnormalities and signs that could indicate disease or other health conditions that would prohibit the animal from entering the food supply \u2022 Procedures to mark and document dispositions of livestock following antemortem inspections \u2022 Methods and procedures to inspect livestock and poultry after slaughter (postmortem inspection) to make and document dispositions of carcasses following post-mortem inspections \u2022 Procedures to verify State inspected establishments that slaughter cattle and establishments that process the carcasses or parts of cattle are complying with 9 CFR 310.22, requiring the removal, segregation, and disposition of specified risk materials (SRMs) \u2022 Methods and procedures used to document and maintain case files supporting administrative enforcement and other actions taken under the authority of FMIA, PPIA, and applicable State laws \u2022 Methods and procedures to assess whether slaughter inspection activities successfully meet the State MPI program management\u2019s expectations for: \u2022 In-Plant Level Slaughter Inspections \u2022 Ante-mortem \u2022 Post-mortem \u2022 Noncompliance regulatory documentation \u2022 Enforcement actions \u2022 Product recalls (e.g., uninspected animals and carcasses) \u2022 Central Office Level Assessments \u2022 Administrative case development Page 29", "\u2022 Program personnel competency Evidence of system application A State MPI program should provide evidence that demonstrates the implementation of a State slaughter inspection system that is \u201cat least equal to\u201d that of the FSIS\u2019s Federal inspection program. At a minimum, the State MPI program should submit: \u2022 Representative State Animal Disposition Summary\PHIS analogous reports that list animal and carcass dispositions performed within the last 12 months \u2022 Documentation of regulatory

control, withholding, suspension, enforcement, or administrative actions taken when noncompliance is identified (e.g., Noncompliance Records (NRs), 30 day letters, Notice of Intended Enforcement (NOIE) letters, Suspension letters, or notification to withhold the marks of inspection) \u2022 Management\u2019s evaluation and results of State slaughter inspection system performance Food Safety Verification System The sanitation criteria incorporate the regulations that address SPS, Sanitation SOPs, and HACCP, which are identified as essential parts of a food safety system. The regulations require that State inspected establishments maintain Sanitation SOPs and meet the SPS requirements. Sanitation SOPs are a prerequisite to an establishment\u2019s HACCP plan, and establishments may use Sanitation SOPs to support decisions in the hazard analysis that certain hazards are not reasonably likely to occur. State inspected establishments may also maintain other prerequisite programs to support decisions in their hazard analyses. The State MPI programs are required to maintain a food safety verification system capable of identifying noncompliances in an establishment\u2019s food safety systems. The State MPI system should have the ability to identify deleterious trends that occur in State inspected establishments\u2019 food safety system (e.g., increased number of NRs, increased positive sample results), and should also be able to document the results of food safety verification activities, including regulatory noncompliance and regulatory actions taken. Additionally, State MPI program managers are required to adopt or create policies for conducting food safety verification activities to ensure compliance with Federal and State laws and regulations. Objective To implement food safety verification activities that ensure all State inspected meat and poultry products found in intrastate commerce are safe, wholesome, not adulterated and properly marked, labeled and packaged, and can verify State inspected establishments comply with applicable State laws, regulations and policies. Page 30", "Food Safety Verification System Methods and Procedures State MPI programs need to implement food safety verification system methods and procedures \u201cat least equal to\u201d those of FSIS\u2019s Federal inspection system. The methods and procedures at a minimum should include: \u2022 Methods to schedule tasks, record food safety verification tasks, and document noncompliance with regulatory requirements \u2022 Procedures to protect the public health by properly verifying State inspected establishments\u2019 compliance with the pathogen reduction, sanitation, and the HACCP regulations \u2022 Procedures to verify that State inspected establishments that slaughter cattle and establishments that process the carcasses or parts of cattle are complying with 9 CFR 310.22 and prescribe to requirements for the removal, segregation, and disposition of SRMs \u2022 Procedures to verify State inspected slaughter operations are implementing sanitary dressing and process control procedures that prevent contamination of carcasses \u2022 Procedures to verify that State inspected establishments implement other prerequisite programs as described and in accordance with 9 CFR 417 \u2022 Procedures for protecting public health by verifying, documenting, and enforcing the requirements for no visible fecal material, milk, or ingesta on livestock carcasses at or immediately after the final rail, and by verifying feces, ingesta, and milk are not present on head meat, cheek meat, and weasand meat \u2022 Procedures for verifying visible fecal material are not present on State inspected poultry carcasses entering the chill tank \u2022 Procedures to protect the public health by properly verifying State inspected establishments\u2019 compliance with the pathogen reduction, sanitation, and the HACCP regulations \u2022 Procedures for holding weekly meetings with State inspected establishment

management to discuss topics pertaining to the establishments\u2019 food safety system and other issues which could affect public health \u2022 Methods to investigate and analyze all food safety aspects (e.g., FSA) that relate to State inspected establishments and their individual products, the design and validity of the establishments\u2019 hazard analyses, HACCP plans, Sanitation SOP, pre-requisite programs, testing programs, and any other programs that constitute the establishments\u2019 HACCP systems \u2022 Methods to categorize State inspected processing and slaughter establishments into a priority level for FSA scheduling, using public health decision criteria, in addition to traditional event-based scheduling Page 31", "\u2022 Methods used to document and maintain case files that support administrative enforcement and other actions taken under the authority of the FMIA, PPIA, and applicable State laws \u2022 Methods to assess whether food safety verification activities successfully meet the State MPI program management\u2019s expectation for: \u2022 In-Plant Level Food Safety Verifications \u2022 SPS \u2022 SSOP \u2022 Prerequisite programs \u2022 HACCP \u2022 Noncompliance regulatory documentation \u2022 Enforcement actions \u2022 Product recalls \u2022 Central Office Level Assessments \u2022 FSA \u2022 Administrative case development \u2022 Program personnel competency Evidence of system application A State MPI program should provide evidence that demonstrates implementation of a food safety verification system \u201cat least equal to\u201d that of the Federal inspection system. At a minimum, the State MPI program should submit: \u2022 Representative HACCP Summary\PHIS analogous reports by State inspected establishments\circuits\districts that list all food safety verification tasks performed within the last 12 months \u2022 Documentation of enforcement and administrative actions taken when regulatory noncompliance was identified (e.g., Noncompliance Records (NRs), 30 day letters, Notice of Intended Enforcement (NOIEs) letters, Suspension letters, withhold the marks of inspection letters) \u2022 In-depth establishment food-safety reviews (e.g., FSAs, and supervisory establishment reviews) \u2022 State issuances and policies that are different than those issued by FSIS \u2022 Completed grant-of-inspection approval process, and withdrawal documents \u2022 Evidence and verification methods that State MPI programs use as an assurance that their program is effectively implemented Page 32", "\u2022 Documentation of actions taken (e.g., rejection of the knock box, suspension) in response to identified SPS, Sanitation SOP, or HACCP noncompliance State MPI programs should submit completed supporting documentation to demonstrate that these programs, as described in the narrative, have been implemented. The State MPI programs need to ensure controls exist and are functioning as intended to maintain their operations over the next 12 months. Non-Food Safety Verification System5 The State MPI program should maintain a non-food-safety verification system that includes methods and procedures for verifying that State inspected meat and poultry products are wholesome, not economically adulterated, truthfully labeled, and meet the non-food-safety regulatory requirements. The system should also document identified noncompliances and regulatory actions taken. State MPI program managers should adopt policies for conducting non-food-safety verification to ensure compliance with Federal and State laws and regulations. Objective To implement State inspection activities that ensure all State inspected meat and poultry products found in intrastate commerce are safe, wholesome, not adulterated and properly marked, labeled and packaged to verify State-inspected establishments comply with applicable State laws, regulations and policies. Non-food Safety Verification System Methods

and Procedures State MPI programs need to implement methods and procedures \u201cat least equal to\u201d those of FSIS\u2019s Federal inspection program. The methods and procedures at a minimum should include: \u2022 Methods to schedule and record non-food safety verification tasks, and document noncompliance with regulatory requirements \u2022 Methods to verify State inspected establishments comply with non-food safety regulatory requirements \u2022 Procedures for: \u2022 Observing establishment product formulation \u2022 Verifying the accuracy of labeling \u2022 Observing preparation or processing procedures 5 \u201cNon-food safety consumer protection\u201d refers to consumer protection activities other than those focused directly on food safety and public health. Under the FMIA and the PPIA, FSIS is responsible for ensuring that products are wholesome; are properly marked, labeled, and packaged; and are not economically adulterated or do not contain components that, while not actually unsafe, are undesirable. Page 33", "\u2022 Reviewing establishment records \u2022 Examining product \u2022 Checking product identification, condition and temperature \u2022 Performing a variety of other in-plant measurements, testing, and calculations \u2022 Procedures to verify and determine whether product labels are not false or misleading and meet applicable requirements of 9 CFR 412 (formerly 9 CFR 317.4, 317.5, 381.132, and 381.133). \u2022 Methods to review and approve sketch labels and supporting documentation \u2022 Methods used to document and maintain case files supporting administrative enforcement and other actions taken under the authority of the FMIA, PPIA, and applicable State laws \u2022 Methods to assess whether State non-food safety requirements and label approval verification activities successfully meet the State MPI program management\u2019s expectation for: \u2022 In-Plant Level Non-Food Safety Verifications \u2022 Net weights \u2022 Standards of identity \u2022 Generic label requirements \u2022 Noncompliance regulatory documentation \u2022 Enforcement actions \u2022 Product recalls for non-food safety situations \u2022 Central Office Level Assessments \u2022 Label approval process \u2022 Administrative case development \u2022 Program personnel competency Evidence of System Application A State MPI program needs to provide evidence that its non-food-safety verification system is \u201cat least equal to\u201d \u201d FSIS\u2019s Federal inspection program. At a minimum, the State MPI program should submit: \u2022 Representative Summary or PHIS-analogous reports by establishments\circuits\districts that list all non-food-safety requirement verification tasks performed within the last 12 months \u2022 Final labels including supporting documentation (e.g., sketch labels, label applications, ingredient formulation worksheets) Page 34", "\u2022 Approved label tracking logs \u2022 In-depth establishment reviews (e.g., supervisory establishment reviews) \u2022 Evidence and verification methods State MPI programs use to assure their program is effectively implemented (e.g., label approvals, label reviews) \u2022 Documentation of actions taken in response to non-food safety requirements verification noncompliance Exempt Facility Review System The State MPI program needs to maintain a system to conduct reviews of exempt facilities (either within official State inspected establishments or separate facilities) to determine their compliance with the FMIA, PPIA, applicable State laws, regulations and policies. State MPI program managers should adopt or create policies for conducting reviews of exempt and poultry exempt facilities. Objective To ensure State exempt facilities comply with applicable State laws, regulations and policies. Exempt Facility Review Methods and Procedures State MPI programs need to implement

review methods \u201cat least equal to\u201d those of FSIS\u2019s Federal inspection program. The methods, at a minimum, should include: \u2022 A review of the State exempt operation to verify livestock and poultry carcasses and products are: \u2022 Not adulterated or misbranded \u2022 Handled humanely (livestock) \u2022 Prepared under sanitary conditions \u2022 Properly marked and packaged \u2022 Stored separately from State inspected products \u2022 Documented according to regulatory requirements \u2022 A method to assess whether the State exempt facility activities successfully meet the State MPI program management\u2019s expectations Page 35", "Evidence of system application A State MPI program needs to provide evidence that demonstrates implementation of an exempt facility review system that is \u201cat least equal to\u201d that of FSIS\u2019s Federal inspection system. At a minimum, the State MPI program should submit: \u2022 Documentation and tracking logs for State exempt facility reviews \u2022 Management\u2019s evaluation and results of the State exempt facility review system performance New Issuance Review System Objective The new issuances list is updated quarterly and is used to verify that State MPI programs are staying current with new FSIS policies. FSIS routinely issues regulations and notices in the Federal Register to communicate new policies and requirements to the public. FSIS also routinely issues Directives and Notices to Federal IPP to provide direction and guidance regarding inspection and enforcement activities. Each quarter, FSIS provides State MPI programs with an updated list of all applicable issuances published since the previous quarter. FSIS continues to provide this information in an effort to better communicate the \u201cat least equal to\u201d criteria for State MPI programs. State MPI programs are to review all issuances and incorporate any necessary modifications in their programs. State MPI programs are to submit a response to the Quarterly List of Applicable FSIS Issuances within 30 days after receipt of the list. New Issuances Methods and Procedures While State MPI programs are not required to follow FSIS issuances verbatim or to issue similar documents to their inspection program personnel, they need to consider the implications of each issuance and are expected to be able to explain their \u201cat least equal to\u201d actions (even if their decision is to do nothing) related to the activity or issue covered by the FSIS issuances. When a policy is issued by FSIS, State MPI programs need to have methods in place to determine the applicability of the policy to their State program, and decide how to communicate instructions for its implementation within their State inspection programs. The State\u2019s results will be documented as a response to each new issuance on the Quarterly List of Applicable FSIS Issuances. For each new issuance, using one of the alternatives listed below, the State MPI program should document that the State: \u2022 Determined that the issuance has no application for its State MPI program maintaining its \u201cat least equal to\u201d status; the State should fully explain why; Page 36", "\u2022 Adopted essentially the same approach in its State MPI program; and submitted documentation demonstrating implementation; or \u2022 Adopted measures in the State MPI program that the State considers to be \u201cat least equal to\u201d FSIS\u2019s Federal inspection program; provided the reason and justification for doing so, explained why and how they became convinced that they are \u201cat least equal to\u201d FSIS\u2019s Federal inspection program, and provided documentation demonstrating implementation. Evidence of system application State officials need to be able to provide a justification for their \u201cat least equal to\u201d determination for each new Federal issuance. State MPI programs are to respond to the Quarterly List of Applicable FSIS Issuances

sent on or before the first day of each quarter of the Federal fiscal year (e.g., October, January, April, and July) within 30 calendar days of receipt. The response should include a description of the methods used to distribute the issuances and evidence of delivery, and a summary of how the new issuance or policy change is being implemented. States should submit any documentation that demonstrates how each issuance was implemented. Examples of the manner in which issuances are implemented are included in the Quarterly List of Applicable FSIS Issuances. However, other documents may be used to demonstrate the implementation. States should enter information into the designated column on the Quarterly List of Applicable FSIS Issuances, and attach the responses to an email to the Federal State Audit Branch (FSAB) at: StateMPIProgramSubmissions@fsis.usda.gov, or by USPS, FedEx, UPS, or FAX (402-344-5104). Page 37", "Attachment 3 \u201cAt Least Equal To\u201d Data System Guidance for State Cooperative Meat and Poultry Inspection (MPI) Programs Electing Not to Use Public Health Information System (PHIS) I. PURPOSE To provide guidance to State Cooperative Meat and Poultry Inspection (MPI) programs electing to use a data system other than FSIS\u2019s PHIS for meeting the \u201cat least equal to\u201d data system essentials. II. BACKGROUND The Federal Meat Inspection Act (FMIA) (21 U.S.C. 661) and the Poultry Products Inspection Act (PPIA) (21 U.S.C. 454) authorize FSIS to cooperate with State agencies in developing and administering their own Meat and Poultry Inspection programs. Individual State MPI programs are required to operate in a manner and with authorities that are \u201cat least equal to\u201d the ante-mortem and post-mortem inspection, reinspection, sanitation, recordkeeping, and enforcement provisions as provided for in the FMIA and PPIA. Therefore, State MPI programs are required to develop a data system with characteristics that can produce inspection and recordkeeping outcomes \u201cat least equal to\u201d FSIS\u2019s procedures. FSIS maintains PHIS as its data system. FSIS developed PHIS to maintain detailed records of regulatory compliance verification activities. The activities are conducted by FSIS\u2019s Federal inspectors and the information is entered into PHIS by FSIS personnel at official establishments, official import establishments, and registered facilities. The PHIS database maintains establishment and facility data, and the results of inspection verifications. FSIS uses this information to identify issues that require Agency attention. PHIS supports documentation of appeals to inspection decisions, scheduling, and documentation of Food Safety Assessments (FSA) and the ability to identify and notify suppliers of beef products that have tested positive for E. coli O157:H7. FSIS uses PHIS to manage FSIS\u2019s inspection assignments and FSIS\u2019s employee assignments to roles and establishments. The PHIS sample scheduler distributes product sample requests to Establishment Task Lists. FSIS uses PHIS to apply business rules and risk-based algorithms for sample selection and output reports of scheduled samples. These scheduled sample requests tasks are performed by FSIS\u2019s Federal IPP. FSIS uses PHIS to process information about imported products. FSIS\u2019s Federal IPP input reinspection results for imported products in to PHIS. PHIS\u2019s functionality includes a means for FSIS\u2019s Office of Policy and Program Development (OPPD), International Equivalence Staff (IES) and the Office of Investigation, Enforcement and Audit (OIEA) Management Control and Audit Staff (MCAD) to schedule and track foreign country audit activities. Page 38", "The information held in PHIS is shared with the Microbial (M2K) transactional database and the FSIS data warehouse. Information is written to the data warehouse from the PHIS transactional database to be used by other systems including the

Enterprise Reporting System (ERS). The FSIS data warehouse provides a source of legacy system data which is used to support the analysis of inspection, audit, and assessment outcomes, and it maintains data from VetNet and PulseNet. FSIS analyses the data collected in PHIS through its regulatory verification, compliance and enforcement, and sampling activities to assess the appropriateness of policy design and policy implementation. The analysis informs further policy development. Additionally, FSIS uses the information gathered from data analysis to ensure that policy and program components are effective in meeting the FSIS\u2019s public health goals and objectives. FSIS recognizes that an integrated infrastructure with high-quality data and feedback interaction is essential to a data-driven approach to inspection. A data-driven approach to inspection requires quality data collection methods, ongoing data analysis to refine analytical decision-making tools, and performance measures to assess the impact of policies and programs. The Task Library in PHIS supports the assignment of tasks to Establishment Task Lists. Each task is distributed to the Establishment Task List with a due date for completing the task. FSIS\u2019s Federal IPP have the ability to schedule the assigned tasks by moving the tasks from the Establishment task List to the Establishment Task Calendar. FSIS designed PHIS to allow IPP the flexibility to decide on which days they will perform the tasks. Alerts are issued when specific events requiring immediate attention occur. Alerts are also used to remind FSIS\u2019s Federal IPP to take a particular action, such as, acquiring a product sample for laboratory analysis. An alert consists of a \u201ctrigger\u201d and a \u201cnotification\u201d function. The trigger is a feature that automatically scans the data for a specific event, and upon finding it, issues the notification. The notification can take the form of an email sent by PHIS, a message on the user\u2019s PHIS Alerts Dashboard, or both. PHIS issues Public Health Regulation (PHR) alerts when there is a pattern of noncompliance at the establishment. Each month the Office of Data Integration and Food Protection (ODIFP) uses the results of inspection tasks to calculate the PHR noncompliance rate for each meat and poultry establishment as well as egg products plants. A PHR alert is issued to FSIS\u2019s Federal IPP when an establishment has a noncompliance rate that is elevated. Examples of other events that trigger alerts are: a large number of inspection tasks not completed at an establishment, high rates of noncompliance in an establishment, and a positive adulterant pathogen test result at an establishment (e.g., Escherichia coli (E. coli) O157:H7 in raw ground beef, Shiga toxin-producing Escherichia coli (STEC) in beef manufacturing trimmings, or Listeria monocytogenes (Lm)\u201c/Salmonella in ready-to- eat (RTE) products). The alert text gives directions to FSIS\u2019s Federal IPP by pointing them to the appropriate regulations and directives needed for the response. PHIS Dashboard Alerts and e-mail notifications are issued to Headquarters and FSIS\u2019s Federal IPP as events occur. The alerts and notifications provide FSIS\u2019s Federal IPP and FSIS\u2019s Headquarters personnel with information that is important to the execution of their work assignments. The PHIS includes a set of standard reports available to all FSIS administrative levels. FSIS produces a wide range of PHIS reports. The reports are run by FSIS personnel on an as needed basis. The reports are run for specific time frames identified by the user. The reports are available to FSIS personnel based on their assigned PHIS role. So, District management teams see aggregated reports for a District while FSIS\u2019s Federal IPP assigned to an establishment see reports for the assigned establishment. An example of a standard report is the monthly report of noncompliances by FSIS District Offices. Reports are used at all levels of FSIS to monitor operations, to identify areas needing corrective actions, and

to communicate progress towards goals. Users can review the reports and identify results that require investigation and establishment response. PHIS reports provide FSIS\u2019s Federal IPP and FSIS\u2019s Headquarters personnel with information that is important to the execution of their work assignments.

### III. ELEMENTS OF AN \u201cAT LEAST EQUAL TO\u201d DATA SYSTEM

To be \u201cat least equal to\u201d the FSIS\u2019s system, the State MPI data system needs to:

- \u2022 Collect, analyze and respond to State inspected establishment and State MPI program data;
- \u2022 Monitor data streams to determine State inspected establishment performance; and
- \u2022 Respond, near real-time, to State inspected establishments that may pose a risk to public health

To be \u201cat least equal to\u201d the State MPI data system needs to collect data from the following four activities:

- \u2022 Daily inspection verification activities at operating State inspected establishments
- \u2022 State MPI program HACCP verification testing
- \u2022 State MPI program in-depth food safety reviews
- \u2022 State MPI program administrative enforcement actions

Set out below are guidance and recommendations for State MPI programs to use in developing their data systems if they choose not to participate in PHIS. State MPI programs should monitor data collected from the four activities listed above. The data collected should be compared to different data sets (e.g., data of multiple circuits, data Page 40," of multiple establishments, and data from previous months) and analyzed to determine whether the State MPI program is meeting program goals and objectives. State MPI programs should take appropriate actions, based on the analysis, when goals and objectives are not being met.

1. Daily inspection verification activities at operating State inspected establishments

Data Collection State MPI programs need to collect State inspected establishment demographics (profiles). These profiles should include critical up-to-date information about the establishment\u2019s size, products produced, production volume, recall history, noncompliance history, and food defense plans. HACCP information for the establishment should be available in the profile and include summary information, processing categories, food safety hazards, critical control points, and prerequisite programs. A State MPI program should ensure State IPP are able to verify that State inspected establishments\u2019 profile information is accurate and current at set intervals (e.g., at least every thirty days or whenever the HACCP plan changes).

NOTE: By August 1st of each year, FSIS provides State MPI programs with guidance on the PHIS inspection tasks. The FSIS PHIS Inspection Task Catalog will be updated annually to reflect current PHIS task information and then distributed separately as an addendum to the State MPI programs.

Data Analysis The State MPI program\u2019s data system should contain public health-based decision criteria to identify State inspected establishments requiring more frequent inspection activities (e.g., increased directed food safety verification tasks). The State MPI program\u2019s data system should also include a mechanism to react to State inspection results. Examples of events or trends that would trigger the State MPI program to react to State inspection results include:

- \u2022 A large number of inspection activities not completed in State inspected establishments;
- \u2022 High rates of non-compliance in State inspected establishments;
- \u2022 A positive pathogen test result in State inspected establishments (e.g., E. coli O157:H7 in raw ground beef or Lm in RTE products)
- \u2022 Infrequent State inspected establishment profile updates (e.g., HACCP plan changes failed to be identified or documented)
- \u2022 Tasks are not being performed at frequencies sufficient to ensure the safety of public health Page 41","The State MPI programs should ensure data quality and accuracy so that the integrity of the information is not compromised (i.e.,

system identifying outdated establishment profile information or unperformed tasks). 2. State MPI program HACCP verification testing Data Collection The State MPI programs should maintain a system for tracking pathogen and residue testing results. Data Analysis The State MPI program's verification testing system should contain public healthbased decision criteria to identify establishments requiring more frequent inspection activities (e.g., increased directed sampling due to positive sampling results or concerns with establishment's production process). The system should include a mechanism to react to sampling results. Examples of events that would trigger the State MPI program to react to sampling results may include but are not limited to: A large number of sampling activities not completed at State inspected establishments A large number of laboratory discards Positive sampling results in State inspected establishments for adulterant pathogens (e.g., E. coli O157:H7 in raw ground beef, STEC in beef manufacturing trimmings, or Lm/Salmonella in RTE products) Violative residues Identifying long-term processes that may have exceeded their schedule (e.g., a Salmonella sample set that has not been finished) 3. State MPI program in-depth food safety reviews State MPI programs should have procedures (e.g., Food Safety Assessments (FSA)) to verify that an establishment's food-safety systems are effective and yielding products that are wholesome and not adulterated, properly marked, labeled and packaged. Data Collection A State MPI program system should track routine and "for cause" in-depth foodsafety reviews. Data Analysis Page 42,"The State MPI program's data system includes a mechanism to react to sampling and inspection results that could lead to a "for cause" in-depth food safety system review. Examples of events that may trigger the State MPI program to conduct a "for cause" in-depth food safety system review may include, but are not limited to: State inspected establishments not in compliance with specific laws and regulations A positive for STECs in raw ground beef or raw ground beef components A positive Lm or Salmonella in RTE products or a positive Lm food contact surface sample A Class I recall or a food-safety-related enforcement action (e.g., Notice of Intended Enforcement) that is not the result of an in-depth food safety system review State inspected establishments that fail Salmonella or Campylobacter performance standards A State inspected establishment that is the supplier of a product that tested positive for STECs in raw beef products Human illness linked to a product from a State inspected establishment A State inspected establishment that has a high level of public health-related Non-compliance Records (NR) 4. State MPI program administrative enforcement action State MPI programs should have procedures in place to initiate enforcement actions, as needed, to ensure food safety compliance. Data Collection The State MPI programs should maintain a system to collect data and facts to support administrative enforcement actions, and to track the results of actions taken (e.g., NRs, in-depth food-safety system reviews, intensified verification testing (IVT), suspensions, and recall information). Data Analysis The State MPI program's data system should include a mechanism to react to the data collected in support of administrative enforcement actions. Examples of events that may trigger the State MPI program to take administrative enforcement actions may include: Positive STECs in raw ground beef or raw ground beef components Page 43,"Positive Lm, Salmonella, or E. coli O157:H7 in RTE products or a positive Lm food-contact-surface sample A State inspected establishment that is the supplier of a product that tested positive for STECs in raw beef

products \u2022 Human illness linked to State inspected product from an establishment (possible recall) \u2022 State inspected establishments not in compliance with specific State laws and regulations An explanation of the data system and supporting documents should be included in the annual State Self-Assessment that is submitted to the Federal State Audit Branch by November 1 of each year.

Public Health Regulation List, Fiscal Year 2017

<http://www.fsis.usda.gov/wps/portal/fsis/topics/data-collection-and-reports/fsis-dataanalysis-and-reporting/data-reporting/public-health-regulations> Page 44", "Criteria for \u201cat least equal to\u201d Determination Each State MPI Program needs to submit a current narrative describing the complete verification sampling program used to evaluate the effectiveness of each State inspected establishment\u2019s food safety system. The narrative should identify the various chemical and microbiological sampling projects that are a part of the State MPI program\u2019s verification sampling program. The State MPI program should ensure that the product and the production environment are tested for microbiological contaminants or chemical residues, in a manner that is \u201cat least equal to\u201d FSIS\u2019s Federal sampling programs. NOTE: State MPI programs should not include any sampling activities (e.g., generic E. coli) conducted by establishments in the narratives. State MPI programs need to submit documentation that the verification sampling programs, as described in the narrative, have been implemented and have been functioning as intended over the last 12 months. Documentation should include factual information on the State\u2019s ability to maintain its program for the next 12 months. State MPI program officials report laboratory sample results per sample project in an easy-to-read format of the State MPI Program Sampling Activity Table (Attachment 4, page 5051). To be considered \u201cat least equal to\u201d FSIS\u2019s Federal inspection program in its verification sampling program, at a minimum, the State MPI sampling program needs to include the following criteria:

\u2022 Sampling Project Eligibility \u2013 State MPI programs consider product risk, product class, the product\u2019s intended use, and production volume when determining the eligibility for each sampling project. State programs are to include the criteria for determining the scope of sampling, including the frequency of scheduled samples on an average basis per year across all applicable State inspected establishments.

\u2022 Sample Result Analysis \u2013 State MPI programs analyze sample results for trends (e.g., samples collected but not analyzed, increased positive test results, and product non-availability for sample collection) that may influence program inspection activities.

\u2022 Response Plan for Positive Test Results \u2013 State MPI programs have action plans for responding to positive results, including actions taken by the State MPI program to recall product (See Component 6) and prevent adulterated product from entering commerce.

\u2022 Sampling Project Adaptability \u2013 The State MPI program\u2019s sampling verification projects should be adaptable to keep pace with changes, such as emerging Component 3: Sampling Programs Page 45", "pathogens, new products and

processes, new or revised policies, and new laboratory analytical methods. By August 1st of each year, FSIS provides State MPI programs with guidance on minimum testing frequencies for small and very small establishments. State MPI programs need to maintain a verification testing program, with laboratory capacity, to address food safety (e.g., adulterants) and other regulatory requirements (e.g., standards of identity, species identification). The verification program needs to include more specific criteria for routine analysis for the following product classes: Raw Product \u2022 Adulterant \u2022 Shiga toxin-producing Escherichia coli (STEC) in non-intact beef or intact product used to produce non-intact beef \u2022 Violative chemical compound residues (e.g., antibiotic drugs, pesticides, etc.) \u2022 Measure of food-safety system process control \u2022 Pathogen reduction performance standards for Salmonella in certain raw meat and poultry products. \u2022 Pathogen reduction performance standards for Campylobacter in certain raw poultry products. Ready-to-eat (RTE) product \u2022 Adulterant \u2022 Salmonella in meat and poultry products \u2022 Listeria monocytogenes in meat and poultry products NOTE: Listeria monocytogenes is also a food-contact-surface and environmental contaminant associated with meat and poultry products. Thus, the sampling project (e.g., routine Listeria monocytogenes (RLm) sampling project) needs to address the post-lethality environment in which RTE products are produced. State MPI programs need to have the capability to conduct the following analyses as needed: Raw and ready-to-eat (RTE) product \u2022 Adulterant Page 46", "\u2022 Unexpected biological, chemical, or physical hazards sufficient to cause illness (e.g., allergens) \u2022 Misbranding \u2022 Significant nutrition labeling deviations \u2022 Central nervous system tissue in boneless meat derived from advanced meat recovery systems \u2022 Species not identified on the label NOTE: It is not expected that the State MPI programs have a special laboratory for atypical analyses (e.g., bovine tuberculosis), but rather, that the State MPI program be able to procure atypical analyses when needed. Outcome When objectively reviewed by FSIS, the State MPI Program is determined to be \u201cat least equal to\u201d the Federal inspection system. The State MPI program has a system for preventing products adulterated with pathogenic bacteria or violative residues from reaching the public through reliable and timely laboratory analyses of samples. \u201cAt least equal to\u201d requirements State MPI programs should maintain a system for periodic verification of each State inspected establishment\u2019s food-safety system. NOTE: State MPI program Directors are to submit the data integrity information for the data collected and maintained in a system elected in place of PHIS. The data collected may include State laboratory or contract laboratory sample test results. The data integrity information should include: \u2022 The type of data maintained in the State MPI program system elected in place of PHIS (e.g., FSAs, custom exempt reviews, NOIEs). \u2022 How the State MPI program\u2019s data integrity is maintained (e.g., restriction to access the data, ability to track data changes). \u2022 The State law or administrative rule governing the security and integrity preservation of meat and poultry inspection program records. Objective To verify the effectiveness of each State inspected meat and poultry establishment\u2019s food-safety system to ensure that only safe, wholesome, not adulterated, properly marked, labeled and packaged meat and poultry products enter commerce. Page 47", "Verification Sampling Methods and Procedures State MPI programs need to apply verification sampling methods that are \u201cat least equal to\u201d those of FSIS\u2019s Federal inspection program. At a minimum, to \u201cbe at least equal\u201d verification sampling program methods need to: \u2022 Create sampling

frequencies based on product risk, product type, production volume, time of year, product availability, etc. \u2022 Ensure current sampling projects include all State inspected establishments producing eligible products (e.g., raw beef non-intact, RTE post-lethality exposed (see 9 CFR 430)) \u2022 Ensure current sampling projects include all State inspected establishments slaughtering eligible livestock and poultry classes and use the Kidney Inhibition Swab (KIS\u2122) test to screen for violative drug residues in applicable livestock NOTE: The KIS\u2122 test can detect residues for Tilmicosin, Tulathromycin, Bacitracin, Penicillin G, Neomycin, and Sulfonamide. \u2022 Respond to public health concerns associated with products that test positive for adulterants (e.g., increase inspection activity, perform \u201cfor cause\u201d FSA, conduct Intensified Verification Testing (IVT), initiate product recalls) \u2022 Respond to performance standard failures (e.g., based on Salmonella Performance Standards, Campylobacter Performance Standards) \u2022 Analyze sample results for trends (e.g., samples collected but not analyzed, increased positives results, product not available for sample collection) \u2022 Respond to adverse trends (e.g., adapting sample frequency, evaluate State inspection program personnel (IPP) understanding of sample collection) \u2022 Obtain serotype and Pulse-Field Gel Electrophoresis (PFGE) patterns of positive pathogens (partner with FSIS) \u2022 Assess whether sampling activities successfully meet the State MPI program management\u2019s expectation for: \u2022 Creating sampling frequencies \u2022 Sampling eligibility \u2022 Responding to positive sampling results \u2022 Managing positive pathogen results \u2022 State IPP competency Evidence of System Application Page 48", "A State MPI program needs to provide evidence that demonstrates implementation of a verification sampling program that is \u201cat least equal to\u201d FSIS\u2019s Federal inspection program. At a minimum, State MPI programs should submit: \u2022 A list of applicable sampling projects that identify the target agent (microbial or chemical), eligible establishments, projected sampling frequency, actual samples analyzed, and the number of positive or violative samples \u2022 Completed tracking log showing the scheduling and collection of samples per project (both microbiological and chemical) \u2022 Laboratory results (e.g., completed lab forms) \u2022 Documentation verifying how sample integrity is maintained (e.g., use of sample seals) \u2022 Directed and inspector generated residue sampling and results \u2022 Follow-up actions to positive results (e.g., recall actions, \u201cfor cause\u201d FSA, IVT, administrative enforcement) The information can be submitted using the table below or in another format.

Page 49", "Attachment 4 State MPI Program Sampling Activity Table (Suggested Format)

Name of State Agency:	Sampling Dates Covered:	Microbial and Residue Sampling	Number of ESTs Eligible for Sampling	Number Samples Targeted per EST (Intended Frequency)*	Number of Samples Actually Requested	Program wide Number of Viable Samples Analyzed per Program wide	Number of Confirmed Positives
		E. coli O157:H7 in raw ground beef and Salmonella (MT43)					
		E. coli O157:H7 and Non-O157 STEC (O26, O45, O103, O111, O121, O145) in raw beef trimmings (MT60)					
		E. coli O157:H7 in components other than trim (MT64)

Names and addresses of all laboratories used: (attach additional sheets if needed) Name: Address: Phone number: Salmonella in RTE products \u2013 risk based per 9 CFR 430 (IVT\*\*) Microbial and Residue Sampling # ESTs Eligible for Sampling # Samples Targeted per EST (Intended Frequency)\* # Samples Actually Requested Program wide # Viable Samples Analyzed per Program wide # Confirmed Positives Program wide Salmonella in Young Chicken Salmonella in Young Turkey Salmonella in comminuted Chicken Salmonella in comminuted Turkey Campylobacter in Young Chicken Campylobacter in Young Turkey Campylobacter in Ground Chicken Campylobacter in Ground Turkey Salmonella in raw Ground Beef (HC01) Residue Directed Residue inspector Generated Food Chemistry Other Page 51", "Criteria for \u201cat least equal to\u201d Determination Each State MPI program needs to submit a current narrative describing the personnel management system used to staff State-inspected establishments, the training of State inspection program personnel, and the supervision of inspection and compliance enforcement activities. State MPI programs need to submit any supporting documentation (preferably completed reports and documents) to show the system, as described in the narrative, has been implemented, is functioning as intended, and that the State MPI program remains \u201cat least equal to\u201d FSIS\u2019s Federal inspection program requirements for the next 12 months. State MPI program officials report the number of State-inspected establishments and number of State personnel performing duties, States can use the format of the State MPI Program Establishment Count (Attachment 5, page 59) and State MPI Program Employee Primary Roles (Attachment 6, page 60). State MPI programs are required to be \u201cat least equal to\u201d FSIS\u2019s Federal inspection program. The Staffing, Training, and Supervision system at a minimum need to include the following criteria: \u2022 Daily Inspection Coverage \u2013 State MPI programs provide and maintain inspection coverage at State inspected meat and poultry establishments every day the State inspection marks are applied to products; at least once per shift at processing establishments and inspection on the line during all slaughter operations. \u2022 Employee Training \u2013 State MPI programs provide MPI employees with sufficient knowledge, skills, and training that provide them with the ability to carry out State meat and poultry inspection and compliance enforcement duties in a manner that is \u201cat least equal to\u201d FSIS\u2019s Federal inspection program. \u2022 Supervision \u2013 State MPI programs provide direction to daily State inspection and compliance enforcement activities performed by State MPI program personnel. Outcome When objectively reviewed by FSIS, the State MPI program is determined to be \u201cat least equal to\u201d FSIS\u2019s Federal inspection program in its staffing, training, and supervision systems. The State MPI program needs to have: \u2022 State inspectors that perform inspection activities at State inspected meat and poultry establishments, as required by State laws to ensure only safe, wholesome, not adulterated, properly marked, labeled and packaged meat and poultry products receive the State mark of inspection. Component 4: Staffing, Training, and Supervision Page 52", "\u2022 Trained State inspection program personnel

capable of applying State MPI program methods and procedures in accordance with applicable State laws, regulations and directives, and are capable of making sound decisions based upon facts and evidence. \u2022 State MPI program managers and supervisors who can objectively evaluate the effectiveness of implemented program systems and competency MPI of State MPI program personnel \u201cAt least equal to\u201d Requirements The State MPI program needs to maintain: \u2022 A Staffing System, \u2022 A Training Program, and \u2022 A Supervisory System. NOTE: State MPI program Directors need to submit the data integrity information for the data collected and maintained in a system used in place of PHIS. The data integrity information should include: \u2022 The type of data maintained in the system used in place of PHIS (e.g., FSAs, custom exempt reviews, NOIEs). \u2022 How the data integrity is maintained (e.g., restriction to access the data, ability to track data changes). \u2022 The State law or administrative rules governing the security and integrity preservation of meat and poultry inspection program records. Staffing System The State MPI program needs to maintain a staffing system which periodically assesses the State\u2019s personnel needs required to meet the organizational objectives and public health goals. As priorities and needs shift, the State MPI program should be capable of considering changing factors when creating inspection assignments. State MPI programs also should be able to modify staffing policies to accommodate inspection demands of State inspected meat and poultry facilities without compromising the State MPI program\u2019s staffing objectives. Objective To provide daily inspection coverage at State meat and poultry establishments to ensure that only safe, wholesome, not adulterated, properly marked, labeled and packaged meat and poultry products receive the State mark of inspection. Page 53", "Staffing System methods and procedures State MPI programs need to implement staffing methods \u201cat least equal to\u201d those of FSIS\u2019s Federal inspection program. Staffing methods and procedures at a minimum should include: \u2022 Methods to determine the workload (e.g., complexity of State inspected establishment operations, distances between establishments, availability of inspection personnel) of inspection assignments (i.e., single establishment, multiestablishment assignments) and ensure daily inspection coverage is provided at all establishments producing products under the marks of inspection \u2022 Methods to verify inspectors perform required inspection activities on the scheduled inspection days: \u2022 Procedure to analyze staffing data for trends in missed inspections \u2022 Procedure to verify regulatory compliance at an establishment that applies marks of inspection to products on a day when State MPI program personnel miss a scheduled inspection \u2022 Procedure for providing inspection services (i.e., relief coverage) at an establishment when the assigned inspector is absent from duties \u2022 Methods to assess whether staffing successfully meets the State MPI program management\u2019s expectation for: \u2022 Creating State inspection assignments \u2022 Verifying performance of scheduled and missed State inspection activities \u2022 Scheduling relief coverage for State inspection assignments Evidence of System Application A State MPI program needs to provide evidence to demonstrate the implementation of a State staffing system that is \u201cat least equal to\u201d that of FSIS\u2019s Federal inspection program. At a minimum, the State MPI program should submit: \u2022 State staffing documentation (e.g., calendars, inspection activity logs, daily inspection assignments) to support they maintain inspection coverage on each shift at each State inspected establishment on days when the marks of inspection are being applied to products. The documentation should identify any

changes made to inspection assignments to accommodate for annual and emergency leave taken. Page 54", "\u2022 Follow-up documents confirming food safety requirements are met at State inspected establishments on days when products receiving the marks of inspection are produced and the State MPI program is unable to provide inspection services \u2022 Information regarding the number and types of State inspected establishments currently operating under the State MPI program in a plain language format (see the suggested table, State Establishment Count, at the end of this section) \u2022 Information identifying, by job description, the number of State employees who currently perform duties for the State MPI program in a plain language format (see the suggested table, State MPI Employee Primary Roles, at the end of this section) \u2022 A current organization chart identifying all State personnel who carry out aspects of the State meat and poultry inspection at all program levels. The State organization chart should include any personnel who are employed by other State programs outside of the State MPI program to assist in accomplishing their mission. In addition, the organizational chart should show supervisory boundaries and reporting lines of all State personnel involved. The submission of an organizational chart can provide the FSIS audit team with a clear understanding of how each State MPI program carries out its daily operational and administrative functions. Training Program Training and development of employees are key elements to the success of any organization. FSIS invests a considerable amount of time and resources in improving the skills of their workforce. State MPI programs need to have a State program in place to meet the training and development needs of their employees in a manner that is comparable to FSIS\u2019s Federal inspection program. Objective To provide the necessary knowledge, skills, and abilities, through formal and informal training, to ensure personnel can successfully complete inspection and other critical job duties. Training System The training system should include methods that provide State MPI program employees with both formal and informal learning experiences that contribute to individual growth and improved performance in their assigned positions. Formal training courses should be developed to provide employees with sufficient knowledge, skills, and the ability to carry out State meat and poultry inspection or enforcement duties in a manner that is \u201cat least equal to\u201d FSIS\u2019s Federal inspection program. The training methods and procedures at a minimum should address: Page 55" "\u2022 Inexperienced and newly hired employees in performing the specific job positions of the State MPI program \u2022 Ongoing professional and skill development for current employees (e.g., AgLearn courses, field workshops, professional conferences, on-the-job training) \u2022 Core inspection activities (e.g., ante-mortem inspection, humane handling, postmortem inspection, pathogen reduction/HACCP, Sanitation SOPs, Sanitation Performance Standards, Inspection Methods) \u2022 Core compliance enforcement activities (e.g., surveillance, follow-up surveillance, investigation, evidence collection, case development, compliance sample collection) \u2022 Training needs of all State employees who perform MPI program related duties \u2022 Testing criteria used to determine if employees have mastered the objectives and concepts of training courses \u2022 Standards for evaluating the competency of State MPI program trainers \u2022 Techniques for determining whether training activities meet the State MPI program management\u2019s expectations for: \u2022 Newly hired and inexperienced employees \u2022 Experienced employees \u2022 Core inspection activities \u2022 Core compliance enforcement activities \u2022 Assessment of training needs for all State MPI program employees Evidence of system

application A State MPI program needs to provide evidence that demonstrates implementation of a training system \u201cat least equal to\u201d FSIS\u2019s Federal inspection program. At a minimum, the State MPI program should submit: \u2022 A list of training courses offered to State MPI program personnel \u2022 Training certificates for employees\u2019 training completed within the last 12 months \u2022 Tracking logs (e.g., personnel, training class, circuit) \u2022 Management\u2019s evaluation and results of State training system performance Supervisory System A State MPI program needs to maintain a State supervisory system that aligns individual work with its public health and regulatory goals, and ensures recognition of strong performance and correction of unsatisfactory performance. State MPI program managers should adopt or create policies that encourage employee development and strengthen workforce competency. Page 56", "Objective To implement an effective State MPI inspection program, the program managers should establish and effectively communicate clear and measurable employee performance standards, analyze performance results and trends, provide unbiased feedback to assess individual performance, and manage resources.

Supervisory Methods and Procedures State MPI programs need to implement supervisory methods \u201cat least equal to\u201d those of FSIS\u2019s Federal inspection program to ensure effective implementation of the program\u2019s public health and regulatory obligations. The supervisory methods and procedures at a minimum should include: \u2022 Methods and procedures used in developing policies for the State MPI program\u2019s critical inspection and compliance activities: \u2022 Methods and procedures to draft and distribute policies in a timely manner to all State MPI program personnel \u2022 Methods and procedures to assess FSIS issuances (i.e., FSIS Directives, Notices, and Compliance Guidelines) for applicability to the State MPI program \u2022 Methods and procedures to evaluate job performance and competency of State MPI program personnel during their probationary periods (if applicable) \u2022 Methods and procedures to evaluate job performance and competency of all State MPI program personnel to verify all State MPI program policies are implemented (e.g., IPPS, OPPS, annual performance appraisals) \u2022 Methods and procedures to measure and analyze implementation of new and existing State MPI program policies and instructional documents for inspection and compliance activities \u2022

Techniques for determining whether State supervisory activities meet the State MPI program management\u2019s expectation for: \u2022 Distribution and implementation of State MPI program policies \u2022 Employee performance feedback Evidence of System Application A State MPI program needs to provide evidence that demonstrates the implementation of supervisory methods and procedures \u201cat least equal to\u201d FSIS\u2019s Federal inspection program requirements. At a minimum, the State MPI program needs to submit: \u2022 Letters, instructions, memoranda of interview or data tracking logs documenting the distribution and implementation of State MPI program policies regarding critical inspection and compliance enforcement activities Page 57", "\u2022 Completed evaluations of performance standards and results of trend analyses (i.e., reasons why policies are not effectively implemented by State IPP) Completed performance and competency evaluation documents (redacted if necessary) for program employees (e.g., annual performance appraisals, IPPS reviews) States may use the tables below to submit this information. Page 58", "Attachment 5 State MPI Program Establishment Count Suggested Format Name of State Agency: As of Date: Instruction In the section below, list each establishment only once. If the establishment

performs multiple processes, identify the best category that encompasses all the establishment processes. Establishment Type Slaughter Only Processing Only Combination Slaughter and Processing TOTAL Number of State Inspected Establishments Meat Only Poultry Only Combination Meat and Poultry TOTAL Number of Exempt Establishments Meat Only Poultry Only Combination Meat and Poultry TOTAL Number of CIS, TA, or CU Establishments Meat Only Poultry Only Combination Meat and Poultry TOTAL Remarks: Page 59", "Attachment 6 State MPI Employee Primary Roles Suggested Format Name of State Agency: As of Date: # State MPI employees Total: Instruction In the section below, list each employee only once. If the employee has multiple roles, identify the employee under their primary role only and provide details of additional roles in the adjacent comment box. Employee Roles Full time Part time Comments Headquarters\ Central Office Managers Administrative EIAOs VMO\PHVs Other Circuit\Area\ District\Etc. Field Supervisors VMO\PHVs Other In-Plant State Inspection VMO\PHVs Inspectors Relief Other CIS, CU, or TA Inspection VMO\PHVs Inspectors Relief Other Compliance Program Managers Compliance Officers Other Remarks: Page 60", "Criteria for \u201cat least equal to\u201d Determination Each State MPI program needs to submit a current narrative describing the State verification system used to enforce all applicable laws, regulations, and FSIS policies. The system should have the capability to correct any deviations from regulatory requirements that may affect its program being \u201cat least equal to\u201d FSIS\u2019s Federal inspection program in its humane treatment of animals. State MPI programs should submit supporting documentation (e.g. completed reports and documents) to show the State verification system (as described in the narrative, has been implemented) is functioning as intended, and ensures that the State MPI program remains \u201cat least equal to\u201d FSIS\u2019s Federal inspection program over the next 12 months. State verification methods and procedures provided under a State MPI program are \u201cat least equal to\u201d the FMIA, PPIA, HMA, FSIS Directives and Notices, Federal Register publications, regulations, and other applicable policies provided under FSIS\u2019s Federal inspection program in its humane treatment of animals and good commercial practices with poultry. At a minimum, the humane handling system should include the following criteria: \u2022 Humane Slaughter \u2022 A State MPI program verifies all livestock are slaughtered in accordance with one of two humane methods specified in the HMA or applicable State laws. \u2022 The first humane method requires that livestock be rendered insensible to pain on the first application of the stunning device before being shackled, hoisted, cast, or cut. \u2022 The second humane method is in accordance with the ritual requirements of any religious faith that prescribes a method of slaughter where the animal suffers loss of consciousness by anemia of the brain caused by the simultaneous and instantaneous severance of the carotid arteries with a sharp instrument. \u2022 In addition, State IPP are to verify State inspected establishments that slaughter poultry follow good commercial practices described in 9 CFR 381. Outcome When objectively reviewed by FSIS, the State MPI program is determined to be \u201cat least equal to\u201d FSIS\u2019s Federal inspection program in its humane treatment of animals. A State MPI program has capabilities to ensure State inspected establishments humanely handle all livestock presented for slaughter and follow good commercial practices when poultry are slaughtered and processed on premises. Component 5: Humane Handling Page 61", "\u201cAt least equal to\u201d Requirements The State MPI program is required to maintain \u2022 A Humane Handling Verification System. NOTE: State MPI program Directors need to submit data

integrity information for the data collected and maintained in a system elected in place of PHIS. The data integrity information should include: \u2022 The type of data maintained in the elected data system in place of PHIS (e.g., FSAs, custom exempt reviews, NOEs \u2022 How the data integrity is maintained (e.g., restriction to access the data, ability to track data changes) \u2022 The State law or administrative rule governing the security and integrity preservation of State meat and poultry inspection program records Objective To implement State verification activities that ensure State inspected establishments are humanely handling all livestock when presented for slaughter, follow good commercial practices when poultry are slaughtered, and comply with applicable State laws, rules, and policies. Humane Handling Verification System methods and procedures State MPI programs need to implement State slaughter verification methods and procedures \u201cat least equal to\u201d those of FSIS\u2019s Federal inspection program in the humane treatment and handling of animals and good commercial practices with poultry. The methods and procedures at a minimum should include: \u2022 Methods to schedule and record humane handling tasks, and document noncompliance with the requirements consistent with 9 CFR 313 \u2022 Procedures to verify whether State inspected establishment personnel humanely handle all livestock presented for slaughter throughout the time they are on establishment premises \u2022 Methods to conduct and document humane handling verification reviews (e.g., District Veterinary Medical Specialist (DVMS) reviews) at livestock establishments and conduct poultry good commercial practices reviews at poultry establishments \u2022 Methods to assess whether slaughter verification activities successfully meet the State MPI program management\u2019s expectation for: \u2022 In-Plant Level Slaughter Verifications \u2022 Humane handling Page 62","\u2022 Good commercial practices \u2022 Noncompliance regulatory documentation \u2022 Enforcement actions \u2022 Central Office Level Assessments \u2022 Humane handling oversight \u2022 Administrative case development \u2022 Program personnel competency Evidence of System Application A State MPI program needs to provide evidence that demonstrates the implementation of a slaughter verification system \u201cat least equal to\u201d FSIS\u2019s Federal inspection program in the humane treatment and handling of animals and good commercial practices with poultry. At a minimum, the State MPI program should submit: \u2022 Documentation of regulatory control, withholding, suspension, enforcement, or administrative actions taken when humane handling noncompliance is identified (e.g., NRs, 30 day letters, NOIE Letters, Suspension letters, notification to withhold the marks of inspection) \u2022 Humane handling verification reviews (e.g., DVMS analogous reports, in-depth supervisory establishment reviews) \u2022 Management\u2019s evaluation and results of humane handling verification system performance Page 63","Criteria for \u201cat least equal to\u201d Determination Each State MPI program needs to submit a narrative describing the State\u2019s compliance system used to enforce all applicable laws, regulations, and FSIS policies, and takes appropriate enforcement action in the event that misbranded or adulterated product is identified in commerce. The US Code Title 21, Sections 643, 644, 645 and 460 require businesses to register with the Secretary of Agriculture. FSIS compliance conducts surveillance reviews at these registered firms which may lead to investigations and enforcement actions. Under 21 U.S.C. 661 and 454, FSIS expects the States to impose \u201cat least equal to\u201d FSIS\u2019s Federal inspection program assurances that affected individuals, firms, and corporations are complying with applicable State statutes when producing, transporting,

storing, and distributing meat and poultry products in intrastate commerce. The State MPI program's narrative should address and cite the State MPI program's statutory authority for performing surveillance reviews, investigations, and taking enforcement actions at the following business types: If the State MPI program is not granted statutory authority under State law to review, investigate, or take enforcement actions for any of the business types above, the narrative should identify the State agency with the State's statutory authority and cite the applicable statute. The narrative should also describe how the State MPI program cooperates with the authorized State agency when meat and poultry products are involved in the surveillance reviews, investigations, and enforcement actions. State MPI program officials may provide the narrative information in the plain language format of the Summary of Statutory Authority per Business Type, (Attachment 7, page 69) or another format. FSIS identifies the State MPI program as the State Agency responsible for coordinating with other State agencies to ensure all applicable compliance activities outlined in the guidelines comply with specified laws, regulations, and policies. This includes State or contract laboratories, health departments, law enforcement, State human resources division, and other State regulatory agencies. State MPI programs need to submit supporting documentation to demonstrate the compliance system, as described in the narrative, has been implemented and is functioning as intended, to ensure that the State MPI program remains at least equal to the FSIS's Federal inspection program in its compliance activities over the next 12 months. State MPI program officials may provide a report on compliance activities in a Component 6: Compliance Distributors 3D/4D operators Institutions Warehouses Salvages Restaurants Food banks Animal food Retailers Brokers Renderers Transporters Exempt poultry Page 64,"plain language format of the Compliance Activity Report (Attachment 8, page 70) or in another format. State MPI programs are at least equal to the Federal inspection program in its compliance system activities. Compliance system activities need to include the following criteria: Surveillance - State MPI compliance investigators conduct surveillance of persons, firms, and corporations operating in intrastate commerce who are subject to the provisions of the FMIA, PPIA, HMA, 9 CFR, or State laws as applicable. Investigation - State MPI compliance investigators conduct investigations of apparent violations, food safety incidents, or other allegations or incidents using the FMIA, PPIA, HMA, 9 CFR, or State laws as applicable. Product Control Action - State MPI compliance investigators take appropriate control of product found in intrastate commerce that may be adulterated, misbranded, or has not received the mark of inspection, and ensure proper disposition of such product (e.g., detention, seizure, condemnation, destruction). Case Development and Referral - The State MPI compliance program is to include case development and referral mechanisms to take criminal, civil, and administrative enforcement actions, including sanctions, when firms and individuals violate Federal and State statutes. The State MPI compliance program recommends cases of criminal and civil violations for prosecution by the State legal system, or refers them to USDA, FSIS, OIEA, and CID for action. Outcome When objectively reviewed by FSIS, the State MPI program is determined to be at least equal to the FSIS's Federal inspection program in its compliance activities. The State MPI program has: Assurances that affected individuals, firms, and corporations are complying with applicable State statutes or the Federal Acts when producing, transporting, storing, and distributing meat and poultry products in intrastate commerce Documentation of
