surveillance activities, investigations, and enforcement actions (i.e., including sample collection that supports administrative, civil or criminal actions imposed against individuals or firms that have violated the State\u2019s laws) \u201cAt least equal to\u201d Requirements The State MPI program is expected to maintain: \u2022 A Compliance System Page 65", "NOTE: State MPI program Directors need to submit the data integrity information for the data collected and maintained in a system elected in place of PHIS. The data integrity information should include: \u2022 The type of data maintained in a State compliance system elected in place of PHIS (e.g., Review and Compliance Records, LOW, ROIs, physical evidence). \u2022 Where the State compliance data is stored (e.g., server name, name of SharePoint or share drive, hard copy file cabinet). \u2022 How the State compliance data integrity is maintained (e.g., restriction to access the data, ability to track data changes). \u2022 The State law or administrative rule governing the security and integrity preservation of meat and poultry inspection program records. Compliance System The State MPI program needs to maintain a compliance system to investigate violations of food safety, food defense, and other consumer protection statutory requirements, and controls unsafe or violative products through detentions, seizures, and voluntary recalls. State MPI program managers should create or adopt State compliance policies for conducting surveillance and investigation activities, and the development of cases to ensure the imposition of criminal, administrative, and civil enforcement actions are in accordance with State laws. Objective To ensure State MPI program\u2019s compliance activities are carried out in accordance with applicable State laws, rules and policies, ensuring all State inspected meat and poultry products found in intrastate commerce are safe, wholesome, not adulterated, properly marked, labeled and packaged and all enforcement actions imposed are legally supported. Compliance Methods and Procedures State MPI programs need to implement compliance methods \u201cat least equal to\u201d those of FSIS\u2019s Federal inspection program\u2019s compliance activities. The compliance methods and procedures should include: \u2022 Methods for conducting State surveillance and follow-up surveillance of individuals, firms and corporations operating in intrastate commerce subject to State laws, regulations and policies pertaining to meat and poultry inspection program \u2022 Procedures to prioritize State surveillance resources on intrastate commerce businesses with the highest public health risk Page 66", "\u2022 Procedures to determine the collection of raw ground beef samples for E. coli O157:H7 testing as part of the intrastate commerce surveillance activities at retail stores \u2022 Methods for conducting investigations of apparent violations, food safety incidents, other allegations or incidents subject to State laws, rules, and policies pertaining to the State meat and poultry inspection program \u2022 Procedures for State MPI program compliance investigators to collect, safeguard, and dispose of evidence in the performance of surveillance, investigations and other activities subject to the State laws, rules, and policies pertaining to the State MPI program \u2022 Procedures for State MPI program compliance investigators to follow when detaining or in preparation for seizing meat and poultry products found in intrastate commerce, when there is reason to believe that the products are adulterated or misbranded \u2022 Methods for preparing a report (e.g., Report of Investigation (ROI)) to support findings of apparent violations, food safety incidents, or other allegations subject to the applicable State laws \u2022 Procedures for the evaluation of case documents to support appropriate criminal, civil, or administrative enforcement actions (e.g., letters of warning, consent orders, fines, penalties, hearings) \u2022 Methods for the

State MPI program to determine whether to recommend a product recall \u2022 Methods for documenting, prioritizing, and investigating consumer complaints directly related to State inspected meat and poultry products \u2022 Methods to assess whether compliance activities successfully meet the State MPI program management\u2019s expectation for: \u2022 Surveillance \u2022 Investigation \u2022 Documentation and reports \u2022 Product recall \u2022 Consumer complaints \u2022 Compliance personnel competency Evidence of System Application A State MPI program needs to provide evidence demonstrating the implementation of a compliance system that is \u201cat least equal to\u201d FSIS\u2019s Federal inspection program in its compliance activities. The State MPI program should submit: \u2022 Documentation and tracking logs for surveillance and follow-up surveillance activities of State MPI program compliance officers Page 67", "\u2022 Retail and investigative product sample results \u2022 Complete case files that include reports of investigation, evidence collected, notices of detention, notices of seizure, letters of warning, fines, consent orders, and documentation from legal proceedings. \u2022 Evidence preservation and chain of custody verification documents \u2022 Recall effectiveness checks, public notification of recalls, and other related documentation \u2022 Documentation and tracking logs for consumer complaints \u2022 Documentation and communications for surveillance reviews, investigations, and enforcement actions for the business types where the State MPI program is not granted statutory authority \u2022 Management\u2019s evaluation and results of compliance system performance States can use the tables below to provide this information. Page 68", "Attachment 7 State MPI Program Summary of Statutory Authority per Business Type Suggested Format Name of State Agency: Time Period Covered: Instruction: List the State agency or program that is granted statutory authority to review, investigate, or take enforcement actions for the business types listed. Cite the applicable statute that grants that authority, and describe how the State MPI Program cooperates with the authorized agency. (E.G., a State MPI program may not have authority at retail stores in the State because another State agency has the authority). The State MPI program should provide in this chart the applicable laws State laws and the name of the State agency that has the authority to enforce the laws. Business Type State Agency Granted Authority and Statutory Citation State MPI Program Cooperation with the Authorized Agency (if applicable) Distributors Warehouses Transporters 3D\4D operators Salvages Renderers Food banks Exempt poultry Restaurants Retailers Institutions Animal food Brokers Remarks: Page 69", "Attachment 8 Compliance Activity Report Suggested Format Name of State Agency: Time Period Covered: Compliance Activities TOTAL NUMBER Surveillance per FSIS Directive 8010.1 Distributors, Warehouses, and Transporters 3D\4D Operators, Salvages, Renderers, Food Banks, and Exempt Poultry Restaurants, Retailers, Institutions, Animal Food, Custom Exempt, Abattoir, Processor, Port-of-Entry, Bonded Area, Broker, and Miscellaneous Surveillance Follow-ups Violation Cases or Investigations Referrals to FSIS Letters of Warning Administrative Hearings Consent Orders Court Actions or Prosecutions Consumer Complaints State Recalls Effectiveness Checks Registrations of Meat and Poultry Handlers Miscellaneous Actions \ Special Projects \ Personal Contacts (Please itemize) Detentions TOTAL NUMBER Laboratory TOTAL NUMBER Number of Detentions Retail Ground Beef samples per FSIS Directive 8010.1 Pounds of Product Detained Investigative Samples (other than retail ground beef) Pounds of Product Released Pounds of Product Donated Pounds of Product Condemned Pounds of Product Voluntarily

Destroyed Remarks: Page 70", "Criteria for \u201cat least equal to\u201d Determination State MPI programs need to have product sampling and laboratory methods with capabilities and safeguards that are \u201cat least equal to\u201d FSIS\u2019s Federal inspection program\u2019s product sampling and laboratory methods. State MPI programs should update and maintain their laboratory microbiological and chemical detection methods so they are \u201cat least equal to\u201d FSIS\u2019s Federal inspection program methods as detailed in the FSIS Microbiology Laboratory Guidebook. To achieve and maintain \u201cat least equal to\u201d laboratory methods, each State MPI program should meet the criteria in the following areas: \u2022 Laboratory Quality Assurance programs \u2022 Laboratory Testing Methods Outcome When objectively reviewed by FSIS, the State MPI program is determined to be \u201cat least equal to\u201d FSIS\u2019s Federal inspection program in Laboratory methods. FSIS integrates ongoing documents and on-site reviews of the applicable analytical methods in its annual comprehensive review of State MPI programs. FSIS determines if a participating State MPI testing program is \u201cat least equal to\u201d the corresponding FSIS Laboratory testing program. \u201cAt least equal to\u201d Requirements Sampling methods need to provide analytical results \u201cat least equal to\u201d corresponding FSIS testing programs. Each State MPI program should provide documentation through self-assessment and on-site review to demonstrate that its program includes the following:

1. Laboratory Quality Assurance (QA) Programs State MPI program laboratories, or contract laboratories, should have an appropriate QA program \u201cat least equal to\u201d the methods of FSIS\u2019s laboratories to ensure the reliability and integrity of analytical results. State MPI program laboratories, or contract laboratories, should ensure that each laboratory meets the criteria outlined in the FSIS MPI Program Laboratory Quality Management System Checklist. A laboratory QA program assessment consists of the following:

\u2022 Assurances for sample integrity and identity. Laboratories that analyze samples for State MPI programs maintain procedures to ensure that samples are not compromised within the laboratory. These procedures include a documented Component 7: Laboratory Methods and Quality Assurance Program Page 71", "chain of custody as well as traceability to the sample, equipment, and critical supplies used to analyze the sample.

\u2022 Demonstrated confidence in test results and an assurance that it does not resample or re-test pathogen-positive and non-compliant products

\u2022 Documented program of quality control procedures and an assurance that these procedures are followed

\u2022 Properly trained personnel; suitable facilities and equipment; and verified, calibrated, and maintained equipment in a manner consistent with international norms (e.g., European co-operation for Accreditation (EA) 04/10 or Analytical Laboratory Accreditation Criteria Committee (ALACC) guidance)

\u2022 Appropriate proficiency testing schemes for food analysis

\u2022 Use of validated method protocols

\u2022 Reporting and recordkeeping capabilities that track and link a test result to the correct establishment

2. Laboratory Testing Methods Methods used in support of the State MPI program should be validated for the product type sampled and are to be \u201cat least equal to\u201d FSIS\u2019s laboratory requirements. State MPI programs should provide documentation necessary to explain the methods used and the scientific basis for their selection. Such documentation should include detailed testing method protocols, supplemental testing procedures, and evidence of method validation and sustained proficiency testing for microbiology methods and sustained proficiency testing for chemistry methods. Evidence of analyst training in each subject method should be provided.

Method assessment by FSIS considers the following: Microbiology \u2022 Methods of analysis are designed to detect the lowest possible level of stressed pathogens from State inspected meat, poultry, and environmental samples in accordance with current FSIS testing programs for each pathogen (e.g., the method includes an enrichment step, adequate enrichment time, immunobead capture step for E. coli) \u2022 Methods of analysis are validated through an experimental study. When methods are modified, it may be necessary to conduct a supplemental validation against a reference method (e.g., USDA FSIS Microbiology Laboratory Guidebook (MLG), FDA Bacteriological Analytical Manual, or International Organization for Standardization (ISO) Standards). For validation studies conducted outside Association of Analytical Communities (AOAC), Association Fran\u00e7aise de Normalisation (AFNOR), the French national organization for standardization, or similar organizations, refer to FSIS Guidance for Test Kit Manufacturers, Laboratories: Evaluating the Performance of Pathogen Test Kit Methods at: Page 72", "[http://www.fsis.usda.gov/wps/wcm/connect/966638c7-1931-471f-a79e4155ce461d65/Validation\\_Studies\\_Pathogen\\_Detection\\_Methods.pdf?MOD=AJ PERES](http://www.fsis.usda.gov/wps/wcm/connect/966638c7-1931-471f-a79e4155ce461d65/Validation_Studies_Pathogen_Detection_Methods.pdf?MOD=AJ PERES)

\u2022 Methods of analysis detect the same pathogens as the corresponding FSIS MLG method. Alternative methods are inclusive for strains defined as positive by the biochemical, genetic, and serological confirmation tests described in the FSIS MLG. \u2022 Methods of analysis use appropriately-sized test portions or sampling methodology and frequency for samples offering enhanced opportunity for detecting foodborne pathogen contaminations. Information on the test portions used for FSIS testing programs is available at the USDA FSIS Microbiology Laboratory Guidebook website at the following link:

<http://www.fsis.usda.gov/wps/portal/fsis/topics/science/laboratories-andprocedures/guidebooks-and-methods/microbiology-laboratoryguidebook/microbiology-laboratory-guidebook> \u2022 Each method includes culture confirmation testing using a validated method. If additional non-validated confirmatory tests are performed by the laboratory, those tests are not relied upon to invalidate the previous results. \u2022 Shipping enrichments to a second confirmatory laboratory is avoided. FSIS guidance for evaluating microbiological testing methods are found in the Establishment Guidance for the Selection of a Commercial or Private Microbiological Testing Laboratory at the following link at:

<http://www.fsis.usda.gov/wps/wcm/connect/464a4827-0c9a-4268-8651b417bb6bba51/Guidance-Selection-Commercial-Private-Microbiological-Testing-lab062013.pdf?MOD=AJPERES> Food Chemistry \u2022 Methods of analysis are capable of measuring food chemistry components as a percentage of sample weight. Moisture, protein, fat, and salt are included. FSIS conducts limited food chemistry analysis of products at official establishments when in-plant inspection personnel believe the product is misbranded. \u2022 Acceptable methods of analysis are available on the USDA FSIS Chemistry Laboratory Guidebook website at:

<http://www.fsis.usda.gov/wps/portal/fsis/topics/science/laboratories-andprocedures/guidebooks-and-methods/chemistry-laboratory-guidebook/chemistrylaboratory-guidebook> \u2022 AOAC Official Methods of Analysis for food chemistry are also acceptable. \u2022 Alternative methods for food chemistry analysis are acceptable if they measure the same components with sufficient accuracy. Evidence to support the use of Page 73", "an alternative method includes proficiency-testing data generated by the

State MPI program laboratories or contract laboratories completing the analysis. The FSIS Accredited Laboratory Program (ALP) provides proficiency-testing services for food chemistry. For further information, visit the following link:

<http://www.fsis.usda.gov/wps/portal/fsis/topics/science/laboratories-andprocedures/accredited-laboratories/accredited-laboratories>

Residue \u2022 Information on in-plant screening of residues in meat and poultry products is available at: FSIS Directive 10.800.1, Residue Sampling, Testing and Other Verification Procedures Under the National Residue Program For Meat and Poultry Products NOTE: The results of laboratory analyses are reported simultaneously to the State MPI program and the establishment. Submission of Laboratory Methods and Quality Assurance Records State MPI programs need to submit a list of current State laboratory and contract laboratory test methods along with copies of new or revised methods of Standard Operating Procedures (SOPs) on or before November 1 as part of the annual selfassessment submission process and whenever their methods are changed throughout the year. Submission of revised test method SOPs should be submitted on the Laboratory Method Notification Form available at: FSIS Form 5720-15, Laboratory Method Notification Form State MPI programs should submit a completed State Meat and Poultry Program Laboratory Quality Management System Checklist form available at: FSIS Form 5720-14 - State Meat and Poultry Inspection Program Laboratory Quality Management System Checklist NOTE: States may also submit the information on another easy to read format. State and contract laboratories accredited to ISO 17025, with all applicable methods under their scope of accreditation, should provide current certificates of accreditation and only complete applicable portions of the QA checklist. They should also provide the list of method SOPs along with any updated copies of methods new or revised since the previous year\u2019s submission. The State MPI programs may contract with a laboratory that meets the same requirements and are to ensure that the contract laboratory submits the same documentation as described for State MPI program laboratories. Page 74", "In the submission, State MPI program Directors should divide the document submissions into Microbiology methods, Chemistry methods, and QA records. All three sections should be submitted electronically to the FSIS Outlook mailbox: Statelabinquiry@fsis.usda.gov NOTE: The subject line for all submissions to the FSIS Outlook mailbox should contain the name of the applicable State MPI program to allow efficient routing to assigned FSIS personnel. If hard copies need to be submitted, please mail them to the following address: Director, USDA, FSIS, OPHS, Laboratory Quality Assurance Staff 950 College Station Road Athens, Georgia 30605 On-Site Review of Laboratory Methods and Quality Assurance Records The State MPI program laboratories and their contract laboratories are subject to periodic record and on-site reviews by FSIS to evaluate the QA program in comparison to submitted self-assessments and to verify the accuracy and implementation of the laboratory methods. Records related to FSIS laboratory reviews are submitted to the FSIS Outlook mailbox: Statelabinquiry@fsis.usda.gov Criteria for Review Determination The State MPI programs need to provide accurate documentation to demonstrate that they are operating and will continue to operate in a manner that is \u201cat least equal to\u201d FSIS\u2019s Federal inspection program requirements for the next 12 months. The State MPI program: \u2022 Complies with Federal civil rights laws; \u2022 Complies with USDA civil rights regulations; and \u2022 Achieves the intended outcome. Component 8: Civil Rights Page 75", "Outcome State MPI programs need to be conducted in a

manner that respects civil rights, ensures a non-discriminatory environment, and complies with the laws and regulations cited below. Civil Rights authorities State MPI programs should comply with the following civil rights laws, regulations, and policies: \u2022 Statutory \u2022 Title VI of the Civil Rights Act of 1964, as amended, 42 U.S.C. 2000(d) (discrimination on the basis of race, color or national origin) \u2022 Section 504 of the Rehabilitation Act of 1973, as amended, 29 U.S.C. 794 (discrimination on the basis of disability) \u2022 Age Discrimination Act (ADA) of 1975, 42 U.S.C. 6102 (discrimination on the basis of age) \u2022 Title IX of the Education Amendments of 1972, 20 U.S.C. Section 1681 (discrimination on the basis of sex) \u2022 Regulatory and Executive Orders \u2022 7 CFR Part 15 Subpart A, Non-discrimination in Federally Assisted Programs \u2022 7 CFR Part 15 a, Education Programs or Activities Receiving or Benefiting from Federal Financial Assistance \u2022 7 CFR Part 15 b, Non-discrimination on the Basis of Disability Programs and Activities Receiving Federal Financial Assistance \u2022 45 CFR Part 91, Non-discrimination on the Basis of Age in Programs or Activities Receiving Federal Financial Assistance from HHS \u2022 Executive Order 13166 on Limited English Proficiency, dated August 11, 2000 \u2022 Departmental and Agency Policies \u2022 USDA Regulation 4330-002, dated March 3, 1999, Non-discrimination in Programs and Activities Receiving Federal Financial Assistance from USDA \u2022 USDA Regulation 4300-3, dated November 16, 1999, Equal Opportunity Public Notification Policy \u2022 FSIS Directive 1510.1, Equal Opportunity Notification on Material for the Public, dated January 25, 2001 Page 76", "\u2022 FSIS Directive 5720.3, Revision 1, dated March 14, 2011, Methodology for Performing Scheduled and Targeted Reviews of State Meat and Poultry Inspection Programs; and \u201cAt Least Equal to\u201d Guidelines for State Meat and Poultry Cooperative Inspection Programs, dated July 2008 The statutes, regulations and policies listed above prohibit discrimination on the basis of a person's race, color, religion, sex (including gender identity, sexual orientation, and pregnancy), national origin, age (40 or older), disability or genetic information. It is also illegal to retaliate against a person for complaining about discrimination, filed a charge of discrimination, or participating in an employment discrimination investigation or lawsuit.

Acceptance of annual Federal financial assistance under State/Federal Cooperative agreements triggers Title VI, Section 504, of the Americans with Disabilities Act (ADA). Title IX covers and authorizes compliance reviews of federally assisted program delivery (not employment practices that fall under EEO). Areas of review

1. Civil Rights Assurances Requires the State to submit written assurances that its Federally assisted programs and activities are conducted in compliance with Title VI and other nondiscrimination authorities.
2. State Infrastructure and Program Accountability Requires that State MPI programs identify individuals and offices responsible for ensuring program accountability and its compliance with civil rights laws, regulations, policies and guidelines.
3. Public Notification Requires that all State MPI programs include a public notification system to inform applicants, participants, and potentially eligible persons of program availability, program rights and responsibilities, the program\u2019s policy of nondiscrimination, and the procedures for filing a complaint.
4. Racial and Ethnic Data Collection and Reporting Requires the State to obtain race and ethnic data on potentially eligible populations, applicants, and participants in their program service area.
5. Complaints of Discrimination Assesses the complaint procedures for all complaints alleging discrimination in the delivery of State MPI programs on the basis of race, color, national origin, disability, age and sex. NOTE: Complaints can be processed through State

procedures or can be reported directly to USDA for processing. 6. Civil Rights Training Requires State to ensure all employees involved in administering Federally- assisted MPI programs understand their obligations under civil rights related laws, regulations, procedures, and instructions. Page 77", "7. Disability Compliance Requires that State agencies ensure equal access to State MPI program personnel with disabilities. 8. Limited English Proficiency Requires that State MPI programs provide free language access services to potentially eligible applicants and program participants who are Limited English Proficient (LEP). 9. Compliance with the Age Discrimination Act of 1975 Requires Federal agencies to annually report on steps taken to enforce the Act, including non-employment related affirmative outreach actions of its recipients of Federal financial assistance. Instructions State MPI programs need to complete FSIS Form 1520-1, Civil Rights Compliance of State Inspected Programs (Attachment 9, page 79-80) or provide another easy to read format. The self-assessment Form 1520-1 or format needs to be signed by the designated State Official (such as a Director, Commissioner or Secretary) who would be deemed appropriate and responsible for signing the State-Federal Cooperative agreement and the annual application for Federal financial assistance. Signing the form consents to the assurance that the State\u2019s MPI program is conducted in compliance with all Federal statutes relating to nondiscrimination. The completed form needs to be mailed (hard copy), with an original signature, to the FSIS Civil Rights Staff by November 1st each year.

Submission Address: FSIS Civil Rights Staff 5601 Sunnyside Avenue, Mail Drop 5261 Beltsville, MD 20705-5261 Telephone: 800-269-6912 Fax: 301-504-2141 AskCRD@fsis.usda.gov Page 78", "Attachment 9 Civil rights Compliance of State Inspected Programs Page 79", "Page 80", "State MPI programs need to ensure State agency conformance with USDA 7 CFR Part 3016, Uniform Administrative Requirements for Grants and Cooperative Agreements to State and Local Governments (previously known as the Common Rule). State agencies should follow FSIS Directive 3300.1, Rev. 2,\u201cFiscal Guidelines for Cooperative Meat and Poultry Inspection Programs.\u201d Criteria for Review Determination -- Certification for Component 9 The following actions are necessary to complete the Component 9 certification: 1. Timely submission of the annual budget to FSIS\u2019s Office of Field Operations (OFO) and submission of all data requested (See Section IX, Additional Resources, Procedures for the Preparation of the Cooperative State Meat and Poultry Inspection Program Budget Submissions, page 112) 2. Timely submission of annual indirect cost proposals to the applicable Federal Agency (due within six months after close of State fiscal year). Proposals are sent to the Financial Reviews and Analysis Section (FRAS) of the Financial Management Division (FMD). 3. Timely submission of Federal Financial Reports (SF 425) to FSIS. Quarterly Reports are due within thirty days after the close of each quarter (e.g., 4th Quarter SF 425 is due by October 30). The Final report is due within 90 days of the end of the Federal Fiscal Year (e.g., by December 30). 4. Timely resolution of all corrective action on financial findings pursuant to the onsite fiscal review Documentation Needed for On-site Financial Review and are to be provided to FSIS auditors prior to the onsite financial review. \u2022 State\u2019s centralized accounting reports containing State MPI program expenditures, \u2022 Worksheets or schedules used to reconcile the centralized accounting reports to the SF 425, \u2022 Manual adjustments made to the accounting report expenses (vehicle mileage, terminal leave payments, etc.), \u2022 Monthly, quarterly, or final worksheets or schedules that were used to collect, adjust, calculate indirect costs, and summarize the total costs that were reported on the Expense Reports (SF

425) for the grant years indicated, \u2022 A reconciliation by year of Federal Financial Reports and Federal Share of Expenditures with accounting records for grant years covered by the fiscal review, \u2022 Application for Federal Assistance (Form 424) for the grants years covered by fiscal review, Component 9: Financial Accountability Page 81", "\u2022 Expenditure chart accounts for the grant years covered by the fiscal review, \u2022 Documentation for any other FSIS cooperative agreement renewals (e.g. Public Health Data Communication Infrastructure Systems (PHDCIS), Talmadge-Aiken Overtime (TAOT), Cross Utilization (CU), and Cooperative Interstate Shipping program (CIS) employee roster with the Employee Name, Job Title ID Number, Date of Hire Hourly, Bi-weekly, or Monthly Salary, \u2022 Single or departmental audit reports, \u2022 Detailed organizational chart with employee names, \u2022 Equipment inventory list as defined by State requirements, \u2022 Contractual agreements, \u2022 Procedures for the \u201cPreparation and Review of the Federal Financial Report\u201d, \u2022 List of employee retirements\terminations by quarter (e.g. April-June) with disposition of annual and sick leave balances. This is only required if a State MPI program claims indirect costs and the State\u2019s centralized accounting reports do not have object codes for terminal leave payments), and \u2022 List if applicable names of State inspected plants, inspectors and methods separate from cooperative MPI program reimbursable costs involved in voluntary programs, or 100% State Inspection (defined as inspection of the slaughtering and\or processing of animals that are not covered by the FMIA\PPIA). The above documents are items that State agencies are to send to the FSIS auditors prior to the onsite financial review. Instructions for Self-Assessment The FRAS verifies the State MPI program\u2019s compliance with financial reporting requirements throughout the Federal fiscal year. Financial reporting compliance will be determined by FRAS as outlined in this section entitled \u201cCriteria for review determination \u2013 Certification for Component 9.\u201d If the State agency has satisfied the elements outlined in this section, the State agency will sign the Certification Statement for Component 9 (Attachment 10, page 85) and submit the signed certification statement to the appropriate contact in FRAS in order to completely satisfy self-assessment for Component 9. If the State has not satisfied the elements in this section, the State agency complete the following: \u2022 Submit any outstanding documents for Component 9 Certification to FRAS. For a list of required documents for Component 9 Certification see the section above titled Criteria for review determination \u2013 Certification for Component 9. Page 82", "\u2022 Submit a letter to FRAS indicating the reasons for the State program\u2019s delinquency. \u2022 Upon completion of steps (1) and (2), sign the certification statement at the end of the section entitled \u201cCertification Statement for Component 9,\u201d and submit the signed certification statement to the appropriate contact in FRAS to completely satisfy self-assessment for Component 9. Guidance FSIS Directive 3300.1, Rev. 2, Fiscal Guidelines for Cooperative Meat and Poultry Inspection Programs, contains instructions for the preparation and submission of both the Annual Budget and SF 425. Additional guidance for the submission of SF 425, and Federal Financial Reports, is contained in USDA regulation 7 CFR Part 3016.40 (b)(1). State agency grantees maintain supporting documentation for their final SF 425, and Federal Financial Reports, for three years after submission (7 CFR Part 3016.42). Additional guidance for the analysis of budget submissions is contained in the FSIS document, titled \u201cA Guide for the Preparation of the Cooperative State Meat and Poultry Inspection program Budget Submissions,\u201d dated September 2004

\u201cGuidelines for the preparation and submission of Indirect Cost Proposals are contained in OMB Circular A87, Cost Principles for State, Local, and Indian Tribal Governments, Revised 5/10/04. Annual Assurance Statements FMD\FRAS and OFO provide annual assurance statements to the OIEA Federal\State Audit Branch by February 1st that the State agencies are current in the financial reporting activities required throughout the Federal Fiscal Year. OFO reviews and reports on matters associated with the submission of annual budgets. FRAS will review and report regarding the submission of annual Indirect Cost Proposals, submission of Quarterly and Final SF 425, Federal Financial Reports, and timely responses to financial review findings in the form of corrective action. State agencies need to sign the certification statement and submit it to the appropriate contacts in the FRAS to completely satisfy self-assessment for Component 9. Please follow the general mailing procedures and specific procedures for the listed financial documents: \u2022 Email account for FRAS is: FRAS@fsis.usda.gov \u2022 Physical location mailing address for FRAS is: Financial Reviews and Analysis Section USDA\FSIS\OA\OCFO\FMD\FASMB 5601 Sunnyside Avenue, Mail Drop 5264 Beltsville, MD 20705-5264SF-425 Expense Reports Page 83", "Signed electronic copies are sent to the FRAS email address only. NOTE: Please submit electronic SF 425 only. Do not send the SF 425 to the auditor in charge of the State Agency except as a carbon copy (cc). Indirect Cost Rate Proposals (ICP) Electronic ICPs are sent to the FRAS email address only. NOTE: Please submit only electronic ICPs. Hard copies are to the FRAS physical location mailing address. Billing Rate Proposals (CU\CE\EPI) Electronic copies with signed cover letters are sent to the FRAS email address. NOTE: Please submit electronic billing rate proposals only. Do not email any proposals to the auditor in charge of the State Agency except as a cc. Page 84", "Attachment 10 Certification Statement for Component 9 We, the State agency entitled,

\_\_\_\_\_ for the calendar year ending

\_\_\_\_\_ understand that self-certification for Component 9 entails compliance with the following: \u2022 Timely submission of annual budget to FSIS; submission of all data requested. \u2022 Timely submission of annual Indirect Cost Proposal to the Applicable Federal Agency (due within six months after close of State fiscal year). \u2022 Timely submission of Federal Financial Reports (SFs 425) to FSIS. Quarterly Reports are due within thirty days after the close of each quarter (e.g., 4th Quarter SF 425 is due by October 30). The Final report is due within 90 days of the end of the Federal Fiscal Year (e.g., by December 30). \u2022 Timely resolution of all financial findings pursuant to the onsite fiscal review. I certify to the best of my knowledge and belief that the aforementioned State agency has complied with the applicable directives and guidelines set forward by the Food Safety and Inspection Service Agency for successful and complete self-certification for Component 9, and certify compliance with all Component 9 requirements for the State agency. Typed or Printed Name & Title Telephone (area code, Number and extension) Signature of Authorized Certifying Official Date of Submission Page 85", "IX. ADDITIONAL RESOURCES \u201cAdditional Resources\u201d provides State MPI program Directors with additional information that may be needed to perform business processes related to the budget submissions, training and Federal resources, cooperation between State and Federal Compliance Programs, and reference material for internal controls. Contributors to the new Additional Resources section are OFO, OOEET, and OIEA. Page 86", "OFFICE OF FIELD OPERATIONS (OFO) Resource Management and Financial Planning Staff (RMFPS) Procedures for the Preparation of Cooperative State Meat and Poultry

Inspection Program Budget Submissions General Budget submission guidelines for the Cooperative Meat and Poultry Inspection (MPI) State programs are contained in the FSIS Directive 3300.1, Fiscal Guidelines for Cooperative Inspection Programs. The procedures below provide further details on the preparation of MPI program budget submissions.

I. Current Year Budget Execution Analysis There are two components of the current year budget analysis: a) projection of current year expenditures for determination of fund availability for the current year, and b) determination of a basis for analysis of the budget submission for the ensuing year.

A. Current Budget Execution Analysis 1. The analysis of the current year Cooperative State MPI program budget begins in June of each year. At that time, the Financial Reviews and Analysis Section, Financial Management Division requests that each State Agency to submit their estimated projection of the total current fiscal year obligations by object classes on the Budget Information form (SF-424A). 2. The data is utilized to determine a total projection of estimated fund utilization for all State MPI agencies. Annual estimates allow FSIS to determine any requirement for fund reallocation.

B. Budget Submission Base 1. Data collected serves as an annual expenditure basis for comparison and analysis of budget submissions for the following year.

II. Budget Submission for New Fiscal Year Each August, RMFPS prepares the budget call letter for the next fiscal year. Page 87", "A. Budget Call Letter 1. The budget call letter is addressed to the head of the State agency for each Cooperative State MPI program, and is prepared for the signature of the Assistant Administrator for OFO. 2. The call letter provides specific guidance relative to operational and budgetary considerations that State agencies take into account when preparing the budget submission. 3. The call letter has many enclosures for presentation of the budget submission:

- a. Application for Federal Assistance (SF-424) - Attachment 2-2
- b. Budget Information \u2013 Non-Construction Programs (SF-424A) - Attachment 2-3
- c. Assurances \u2013 Non-Construction Programs (SF-424B) - Attachment 2-4
- d. State Assignment and Employment Report (FSIS Form 5720-5) - Attachments 2-6
- e. State Establishment Profile (FSIS Form 5720-4) - Attachments 2-5

NOTE: The attachment examples are found in FSIS Directive 3300.1, Fiscal Guidelines for Cooperative Inspection Programs

B. Budget Submission Form Requirements FSIS forms 5720-4 and 5720-5 are prepared prior to filling out the other forms.

- 1. Form SF-424 (Application for Federal Assistance) Note that section 15, Estimated funding is consistent with form SF-424A.
- 2. Form SF-424A (Budget Information \u2013 Non-Construction Programs) The amounts in form SF-424A are consistent with the data contained in forms 5720-5 and SF-424. The activities to be used for \u2013 Grant Program Function or Activity\u201d are in-plant, Compliance, Laboratory and other. Costs in section B of Form SF-424A are reported by Object Class Category as follows:

- a. Personnel costs are salaries for State permanent full time (PFT) and other than permanent (OTP) personnel including base salaries, overtime, holiday pay, differentials, lump sum payments and annual and sick leave payments. Costs for contract veterinarians should appear in \u2013 Contractual.\u201d
- b. Fringe Benefits are costs paid on behalf of State employees, including retirement, social security, insurance, clothing allowances, relocation benefits, workmen\u2019s compensation, etc. This object class is calculated as a percentage of salary based on historical data or by using the latest payroll information available. Page 88", "c. Travel provides for travel costs incurred by State employees in the performance of their assigned duties whether paid directly by the State or reimbursed to the employee. Some items used in determining overall travel costs are: mileage costs based on the estimated miles to be traveled times the rate per mile (the state

approved mileage rate or latest approved Federal rate, whichever is lower); vehicle rental costs; motor pool costs; auto leases; repairs for State vehicles; auto insurance; and depreciation. Other allowed expenses include per diem, subsistence, and meal allowances. d. Equipment includes the purchase of durable property with an expected useful life in excess of one year and for more than \$500 per unit or in accordance with the State classification of equipment. Requests for equipment acquisitions are fully justified. e. Supplies include commodities, supplies, materials and other expendable items that are normally expended or consumed within a year of being put to use. They may also be used to form a minor part of equipment. Small equipment, costing less than \$500 per unit, may also be included. When estimating for the budget year, prior year one-time purchases are eliminated. Estimates are based on prior year costs adjusted for inflation. f. Contractual includes all contracts for service in support of the program. The salaries of contract veterinarians are included in this object class. This item includes any contractual laboratory costs. Budget year estimates are based on contract costs adjusted upward for inflation and anticipated changes and downward for discontinued services. g. Other includes all items of expenditure not included in the above object classes.

3. Form SF-424B (Assurances \u2013 Non-Construction Programs) 4. Two copies of FSIS Form 5720-5 (State Assignment and Employment Report). The first shows data on personnel as of September 30 of the current year. The second shows data on personnel positions as projected for the ensuing budget year. In both cases, the OTP positions are shown in terms of PTF. 5. Two copies of FSIS Form 5720-4 (State Establishment Profile) The first shows data on plants as of September 30 of the current year. The second form shows a projection of plants expected to be in the cooperative inspection program during the ensuing budget year.

C. Budget Submission Justifications

State MPI program agencies fully justify and explain all changes in the budget submission compared to the current year estimated expenditures. Justifications Page 89", "are in narrative form referencing the affected object class. If there is no change in level of spending or program, it must be indicated in a narrative form.

1. The justification for the budget submission compares and contrasts current year estimated expenditures, staffing, and workloads with those proposed in the budget submission. Changes in staffing and workload are reflected on forms FSIS 5720-4 and FSIS 5720-5. A narrative explanation accompanies the two forms.

2. Justifications for increases in funding are attached to form SF-424A. The narrative justification explains, by object class, the reasons for changes in expenditure levels, including items such as pay raises, inflation, changes in staffing, and training required to maintain \u201cat least equal to\u201d status. If inflation factors are used to justify an increase for an object class, the rate used, as well as the publication source of the inflation index, should be provided.

3. Justifications for increases in salaries, benefits and other salary changes:

a. Provide the following information for all State employees on an attachment:

1. Name of employee  
2. Position title  
3. Date employee entered on duty  
4. Annual salary  
5. Calculated salary cost for the fiscal year

b. Any promotions are justified by providing the following information:

1. Name of employee  
2. Position title  
3. Annual salary  
4. Date of Promotion  
5. Calculated salary cost for the fiscal year

c. For merit increases, the following is provided:

1. Name of employee  
2. Percentages used and the amount of the increase  
3. Date of increase  
4. Justifications for increases or decreases in travel items are included in the submission:

a. The effective date for change in mileage rate, the current rate, and the new rate  
b. Increases in job assignments Page 90", "c. Increase in travel due to training  
d. Decrease in number of personnel traveling

5. An itemized

list of all equipment to be purchased during the fiscal year. D. Talmadge-Aiken (T\A) Submission State programs with plants inspected under the Federal-State T\A Cooperative Inspection program provide the following information attached to form SF-424A: 1. The number of personnel performing inspection at Federally inspected plants (T\A) 2. Total amount of their salaries 3. Staff years and estimated overtime costs(a staff year equals a full-time workload for an individual for a full year) E. Cooperative Interstate Shipment (CIS) Budget Submission States with plants inspected under the CIS program are to prepare a separate budget request for their CIS program. Each form submitted for base program budget request is also submitted for the CIS program. The CIS program budget request includes specific information for the State CIS program. In some instances States will footnote CIS information on the appropriate forms. Note: The Employee Roster is expanded to include employees working in CIS establishments. If a State employee performs inspection at a CIS establishment in addition to inspection in a cooperative establishment, the appropriate percentages of the employees\u2019 time in each type of establishment noted on the roster. Page 91", "OFFICE OF OUTREACH, EMPLOYEE EDUCATION AND TRAINING (OOEET) Outreach Partnership Division (OPD) The Outreach Partnership Division (OPD) is a part of USDA\u2019s Food Safety and Inspection Service, Office of Outreach, Employee Education and Training. OPD provides information and support to State MPI programs, as well as to operators of small and very small meat, poultry and processed egg products establishments, including State-inspected plants. OPD delivers assistance to State MPI programs and State-inspected plants through several different avenues. Resource Library OPD offers food defense materials, help for dealing with plant emergencies, generic HACCP models and guidebooks, informational DVDs on humane handling, control of Listeria monocytogenes, new plant orientation, compliance guidelines, as well a vast array of other useful food safety resources for industry. These materials are available free of charge and can be shipped on request. For a complete listing of available resources, view the \u201cFood Safety Resources for Small and Very Small Plants\u201d brochure at:

<http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatorycompliance/haccp/resources-and-information/food-safety-resources-svsp-outreach> Small Plant Help Desk FSIS\u2019s Small Plant Help Desk assists operators of small and very small meat, poultry and processed egg product establishments seeking help with agency requirements with direct access to knowledgeable staff specialists. The helpdesk provides assistance to State and local food regulatory agencies (FSIS's partners in keeping meat, poultry and egg products safe for consumers). The Help Desk is open from 8:00 a.m.-4:00 p.m. EST, Monday through Friday, excluding Federal holidays. To speak to a staff specialist during this time, call 1-877-FSISHelp (1-877-374-7435). Customers may also contact the help-desk by email at

InfoSource@fsis.usda.gov. Management of State MPI Directors Contact List OPD manages and keeps an up-to-date list of Agriculture Commissioners and MPI Directors for the 27 States that have their own meat and poultry inspection programs, as well as the States in which FSIS has entered into cooperative agreements with to conduct reviews of custom exempt slaughter and processing operations for OFO. This list is maintained on FSIS\u2019s Web site at:

[www.fsis.usda.gov/wps/portal/fsis/topics/inspection/state-inspection-programs/stateinspection-and-cooperative-agreements/state-officials](http://www.fsis.usda.gov/wps/portal/fsis/topics/inspection/state-inspection-programs/stateinspection-and-cooperative-agreements/state-officials). Page 92", "Monthly State MPI Program Directors Correlation Webinar OPD coordinates a monthly Webinar with all

27 State MPI Directors and their personnel to discuss new FSIS policies and any other issues that States need to know to maintain \u201cat least equal to\u201d status to FSIS\u2019s Federal meat and poultry inspection programs. OPD, in conjunction with FSAB and other FSIS programs encourage States to provide issues or topics that need further clarification before the monthly scheduled Webinar so that the appropriate FSIS subject matter experts can provide updates and answer questions. OPD solicits topics from the State MPI Directors for upcoming Webinars; however, State personnel are also welcome to submit suggestions for Webinar topics through the Small Plant Help Desk. Management and Renewal of Federal and State Cooperative Agreements The FMIA and PPIA allow FSIS to cooperate with State agencies in developing and administering their own MPI programs. OPD administers the base cooperative agreements between FSIS and the individual States to operate their \u201cat least equal to\u201d meat and poultry inspection programs. Provided the State continues to operate it\u2019s \u201cat least equal to\u201d program in good standing, these cooperative agreements are renewed on an annual basis through OPD. OPD administers, and renews, the Tallmadge-Aiken (TA) and Cross Utilization (CU) agreements with States that provide inspection coverage for FSIS-regulated establishments, as well as the Cooperative Interstate Shipment (CIS) agreements where State-inspected establishments can sell product outside of their respective State boundaries and in foreign commerce. OFO has direct oversight of these three programs, and ensures that State inspection personnel assigned to any TA, CU or CIS establishment have received FSIS-conducted training. OPD assists the States that have these programs by ensuring their personnel are registered in the required FSIS-conducted training courses and providing both the States and OFO with the pass\fail results of the State employees. There are several other unique cooperative agreements that OPD administers and renews based on OFO\u2019s needs. There is a cooperative agreement with Utah\u2019s Egg and Poultry Grading Program to have Utah State Inspectors provide continuous inspection in several of FSIS\u2019s egg products inspection plants. Furthermore FSIS has cooperative agreements with California and Colorado for their personnel to conduct reviews of custom exempt slaughter and processing operations within those respective States, which are procedures that OFO would normally perform. Directors seeking advice or assistance with State MPI programs, or wishing to obtain copies of current and archived cooperative agreements, are welcome to contact OPD through the Small Plant Help Desk. Page 93", "Training OPD provides assistance to the State programs by ensuring they receive course announcements from FSIS and any assistance to State personnel in securing enrollment in the classes they might need. This service is especially essential for the States that have TA, CU or CIS programs where their personnel must have successfully completed FSIS trainer-led courses in order to conduct inspection activities within TA, CU or CIS establishments. OPD provides both the States and OFO with the pass\fail results of the State employees. Furthermore, OPD assists States by providing CDs, DVDs, or other hard copy resources on food safety and public health-related training materials for reference offered through FSIS\u2019s Center for Learning. Many of these titles are interactive computer-based training on disk. State personnel can request a copy of the catalog and submit any orders through the Small Plant Help Desk, since the online catalog is only available through FSIS\u2019s Intranet site, which the States cannot access. Page 94", "OFFICE OF INVESTIGATION, ENFORCEMENT AND AUDIT (OIEA) Compliance Investigation Division (CID) Cooperation Between Compliance Investigation Division (CID) and State

Compliance Programs Federal and State Compliance programs are encouraged to integrate and coordinate their respective programs to the maximum extent possible to eliminate or avoid duplication of efforts. CID assists and encourages State Compliance programs in assuming full responsibility for and jurisdiction over the enforcement of meat and poultry laws within States. State Compliance programs assist CID in coordinating and channeling various State efforts into a comprehensive national compliance program. The coordination of CID and State Compliance programs necessitate close communications in administration of the respective programs. The compliance personnel of CID and State Compliance programs are cross-utilized fully to inquire into alleged violations, conduct compliance reviews, develop evaluation material, and make necessary contacts with the various Federal, State, County, or Municipal officials and informants. When there is overlapping jurisdiction and authority, compliance personnel of either CID or State Compliance programs are authorized to handle the matter and represent fully both Federal and State interests. CID and State Compliance programs are encouraged to refer cases dependent on resources to obtain optimal results. These operational details are resolved on a caseby-case basis between CID and State Compliance programs. CID training programs are open for participation by members of both groups to the extent possible and feasible. CID Regions and Contact Information Western Region (CA, HI, AZ, AK, NM, NV, UT, CO, OR, WA, ID, WY, MT) 620 Central Avenue Building 2B, 2nd Floor Alameda, CA 94501 Telephone: 510-769-5733 Southwest Region (TX, OK, KS, MO, NE, IA, SD, ND, IL, MN) 1100 Commerce Street, Room 557 Dallas, TX 75242 Telephone: 214-767-2783 Page 95", "Southeast Region (FL, PR, AR, LA, GA, AL, TN, MS, MD, VA, KY, SC, NC, WV, DE, DC) 100 Alabama Street, SW 1924 Building Suite 3R95 Atlanta, GA 30303-3104 Telephone: 404-562-5962 Northeast Region (PA, NJ, CT, NY, MI, WI, IN, OH, MA, ME, NH, VT, RI) BNY Mellon Independence Center 701 Market Street, Suite 4100 C Philadelphia, PA 19106 Telephone: 215-430-6222 Page 96", "Management Control and Audit Division (MCAD) Development of a Federal Program Management Control System Background The Federal Managers\u2019 Financial Integrity Act of 1982 (FMFIA) requires the General Accounting Office (GAO) to issue standards for internal control in government. The standards provide the overall framework for establishing and maintaining internal control and for identifying and addressing major performance and management challenges in areas at greatest risk of fraud, waste, abuse, and mismanagement. Office of Management and Budget (OMB) Circular A-123, Management Accountability and Control, revised June 21, 1995, provides the specific requirements for assessing and reporting on controls. As a result, Federal program managers continually seek better ways to achieve agencies\u2019 missions and program results. In other words, they seek ways to improve accountability. A key factor in helping achieve such outcomes and minimize operational problems is to implement appropriate internal control. Effective internal control helps manage change to cope with shifting environments and evolving demands and priorities. The term internal control is synonymous with the term management control (as used in OMB Circular A-123) that covers all aspects of an agency\u2019s operations (programmatic, financial, and compliance). Recently, other laws have prompted renewed focus on internal control. The Government Performance and Results Act of 1993 requires agencies to clarify their missions, set strategic and annual performance goals, and measure and report on performance toward those goals. The internal control system helps the program\u2019s management to provide reasonable assurance of the effectiveness and efficiency of operations, of reliability of financial

reporting, and of compliance with applicable laws and regulations. Terminology The following includes definitions for commonly used terms of the Federal management control systems:

- Risk Assessment - Internal control provide for an assessment of the risks the agency faces from both external and internal sources. A precondition for risk assessment is the establishment of clear and consistent agency objectives. Risk assessment is the identification and analysis of relevant risks associated with achieving the objectives, such as those defined in strategic and annual performance plans developed under the Government Performance and Results Act, and forming a basis for determining how risks is managed.
- Page 97", "Internal Control (Management Control) - An internal control is comprised of control activities, control document (control), and performance measures (i.e., performance standards or action level).
- Control - Control documents (control) provide direction to program personnel for the execution of the control activity to meet the expectation of the program's management. Controls are policies, procedures, techniques, and mechanisms that enforce management's directives, such as the process of adhering to requirements for budget development and execution. Controls are clearly documented, and the documentation is readily available for examination. The control document is measurable and appears in management directives, administrative policies, or operating manuals and may be in paper or electronic form. All documentation and records are properly managed and maintained.
- Control Activity \u2013 Internal control activities help ensure that management's directives (mission and strategic goals) are carried out. Control activities are effective and efficient in accomplishing the agency's control objectives. They help ensure that actions are taken to address risks.
- Objective of Control Activity - Objective of control activity specifies the purpose for program in executing a control activity. The purpose of the control activity directly relates to and supports the program's mission and strategic goals.
- Implementation (Monitoring) - Internal control monitoring assesses the quality of the control activity performance over time and ensures the findings of audits and other reviews are promptly resolved.
- Performance Measure - A performance measure (i.e., performance standard or action level) is an indicator of the effectiveness and efficiency of a control activity. Programs need to establish activities to monitor performance measures. These activities may include comparisons and assessments of different sets of data to one another and the performance measures to analyze the relationships so conclusions can be made and appropriate actions taken.
- Controls are aimed at validating the correctness and integrity of the performance measures.

Page 98", "Management Control Helper Questions Key Function (Functional Area) \u2022 Why do we exist? How do we accomplish our program's mission and strategic goals? Does our existence require us to produce any products?

- Risk Assessment \u2022 What can happen if we do not meet our objective? \u2022 How will our failures to meet our objectives affect the program's function or existence? \u2022 How will our failures affect the program's accomplishment of its mission and strategic objectives?
- Control Activity \u2022 What must be done consistently and well for the program to continue to function successfully? (NOTE: This does not relate to how it is done)
- Objective (Desired Outcome) \u2022 What is the objective of the control activity?
- Management Control \u2022 What procedures or activities will provide personnel clear instructions for implementing the control activity and ensure the attainment of the objective? \u2022 How can we demonstrate our implementation of the controls? (proof)

Access.pdf", "type": "pdf", "n\_pages": 2, "word\_count": 920, "text\_by\_page": ["11\03\2016 Steps to Obtain Level 2 eAuthentication Credentials and PHIS Access In February 2015, FSIS announced to countries that are interested in exporting product to the United States (US) the availability of its web-based Self-Reporting Tool (SRT) within FSIS\u2019s web-based Public Health Information System (PHIS). Please refer to the Federal Register announcement (80 FR 9428) for additional information. The benefits for using the web-based SRT are expedited SRT review process, transparency, and security. Each year it will only be necessary for countries to reflect any changes that have occurred within their inspection systems since the last submission of the SRT. Participating countries will be able to log onto PHIS at any time to view their SRT and its status on a personalized homepage. It is important to understand that the level 2 eAuthentication credentialing and PHIS enrollment are two separate processes. It is important to note that when the designated central competent authority (CCA) official becomes level 2 eAuthentication credentialed, the PHIS enrollment process is not automatically initiated. As these processes are independent from one another, it will take time to complete both of these processes. To start the level 2 eAuthentication credentialing process, a country first needs to identify a designated CCA official. This identified official will be responsible for entering the SRT responses and uploading supporting documents into PHIS. This official is responsible for first obtaining level 2 eAuthentication credentials, and then requesting to be enrolled in PHIS to complete the SRT. The following steps clarify how an official can obtain access to the SRT. 1. To obtain level 2 eAuthentication credentials, the official must first complete the level 2 registration form. Please visit <http://1.usa.gov/1rbeFcL> to complete registration. REMINDER: All red asterisk (\*) fields must be filled in to successfully complete the registration form. 2. The official will receive a confirmation e-mail with the subject line, \u201c>eAuthentication - Action Required - Instructions to Activate Your USDA Account with Level 2 Access\u201d within 1 hour. The official must activate the account within seven (7) days to complete the registration form process. Please check your junk e-mail for the confirmation e-mail. For more information on eAuthentication please visit the eAuthentication Help webpage (<https://www.eauth.usda.gov/MainPages/eauthHelp.aspx>) or review the eAuthentication Frequently Asked Questions document ([https://www.eauth.usda.gov/\\_GlobalAssets/Documents/USDA\\_eAuth\\_FAQ.pdf](https://www.eauth.usda.gov/_GlobalAssets/Documents/USDA_eAuth_FAQ.pdf)). If you have not received your confirmation e-mail once you have activated your account, please contact Ms. Monica Marcelli at [monica.marcelli@fsis.usda.gov](mailto:monica.marcelli@fsis.usda.gov) or via telephone at 1 (202) 720-0473. Ms. Marcelli will help the official to schedule the appointment with the Local Registration Authority (LRA) to verify his or her government issued photo identification. If the official is based at an embassy in Washington DC, or visiting Washington DC, he or she can meet with the LRA at the United States Department of Agriculture building to complete the eAuthentication credentialing process. If the official is not in the US, FSIS can make arrangements to complete the credentialing process while in country. 3. Upon confirming the official\u2019s identity, the LRA will send the official a confirmation e-mail stating that level 2 eAuthentication credentials have been granted. Upon receiving confirmation, the official will now be able to enroll in PHIS in order to manage and submit its SRT to FSIS electronically. To enroll in PHIS, visit <https://phis.fsis.usda.gov> and login using your Level 2 eAuthentication credentials. To login, use the same username and password created when the level 2 registration form was completed. Use the following steps to complete the PHIS enrollment process. a. On the

Welcome to FSIS Enrollment Application page, click Submit Enrollment Request. b. On the FSIS Enrollment Request Wizard (1) select Foreign Country, (2) enter the Central Competent Authority contact information, (3) select Central Competent Authority, (4) select your country, and (5) enter specific personal contact information. c. Once you have completed the Enrollment Request Wizard, review. If you need to edit information, click Previous until you get to the desired page to edit. Once complete, click Finish and click Logout eAuth (in upper", "11\03\2016 right hand corner). An enrollment confirmation number will appear. Please document (or print) that number for your records. Once the official has submitted his or her enrollment request for PHIS, please contact Ms. Marcelli to provide her the enrollment number, or the e-mail address or last name of the contact person entered into the PHIS enrollment form. An e-mail will be sent to the official notifying them that their request has been approved. Once PHIS enrollment has been approved if the official cannot log into PHIS after 24 hours, please contact Ms. Marcelli. REMINDERS: Log into PHIS at least every 60 days to prevent your account from being disabled. If the official\u2019s PHIS account becomes disabled, he or she must make sure that his or her level 2 eAuthentication password is up-to-date, and then contact Ms. Marcelli for further assistance. For officials that are enrolled in PHIS, FSIS will send reminder e-mails to log into PHIS. For security reasons, eAuthentication will occasionally prompt you to change your password. If it is time to change your password, the system will prompt you to change your password. If the official is not able to log into PHIS because he or she has locked the level 2 eAuthentication account by trying to enter his or her password too many times, please contact the eAuthentication Help Desk at 1-800-457-3642, and select Option 1 or e-mail eAuthHelpDesk@ftc.usda.gov. The official may be prompted to answer security questions that he or she set up while completing the eAuthentication registration form. Lastly, the USDA does not permit sharing accounts or passwords."], {"file\_name": "FSIS\_GD\_2016\_0013", "title": "Supplemental Questions and Answers on Descriptive Designation for Needle-or Blade - Tenderized (Mechanically Tenderized) Beef Products", "num": "FSIS-GD-2016-0013", "id": "6cb431bef474e08261c5e2a91ad183bdb60fce584011d2274966aeea7c49228", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/import/FAQ-Supplement-2008-0017.pdf", "type": "pdf", "n\_pages": 4, "word\_count": 1229, "text\_by\_page": ["SUPPLEMENTAL QUESTIONS AND ANSWERS ON DESCRIPTIVE DESIGNATION FOR NEEDLE-OR BLADE - TENDERIZED (MECHANICALLY TENDERIZED) BEEF PRODUCTS November 17, 2016 Compliance Documents Q1. Where can I find information on the new \"mechanically tenderized beef products regulation per 9 CFR 317.2(e)(3)? Information on \u201cmechanically tenderized beef products\u201d is available from the following locations: \u201cDocket No. FSIS-2008-0017 | PDF \u201cCompliance Guideline for Validating Cooking Instructions for Mechanically Tenderized Beef Products Labeling Issues Q2. Under this final rule, will the product need to be labeled with the specific method of mechanical tenderization used to prepare the product? No, the label need not include the specific type of mechanical tenderization used. To provide flexibility, FSIS is allowing the phrase \u2018mechanically tenderized\u2019 to be used as the descriptive designation on any type of mechanically tenderized product. In addition, in lieu of \u201cmechanically tenderized,\u201d such product may be labeled as"]}]

\u2018\u2018needle tenderized\u2019\u2019 or \u2018\u2018blade tenderized,\u2019\u2019 as applicable. Q3. Can \u201cneedle injected\u201d be used as the descriptive designation on the labels of raw or partially cooked beef products that have been mechanically tenderized? No, needle injected may not be used as the descriptive designation. The terms \u201cneedle tenderized\u201d or \u201cmechanically tenderized\u201d must be used as the descriptive designation for needle tenderized raw or partially cooked beef products and the terms \u201cmechanically tenderized\u201d or \u201cblade tenderized\u201d must be used as the descriptive designation for raw or partially cooked blade tenderized beef products. Q4. Are the descriptive designations \"mechanically tenderized,\" \"blade tenderized,\" or \u201cneedle tenderized\u201d only required on raw or partially cooked beef products? Yes, unless the product is destined to be fully cooked or to receive another full lethality treatment at an official establishment, such product must be labeled accordingly. Q5. Do the new labeling requirements apply to mechanically tenderized pork, lamb, or goat products?", "SUPPLEMENTAL QUESTIONS AND ANSWERS ON DESCRIPTIVE DESIGNATION FOR NEEDLE-OR BLADE - TENDERIZED (MECHANICALLY TENDERIZED) BEEF PRODUCTS No. The rule applies only to raw or partially cooked beef products that have been mechanically tenderized. Q6. Can establishments put both mechanically tenderized beef products and nonmechanically tenderized beef products in the same immediate container and label it with the descriptive designation \u201cmechanically tenderized?\u201d No. To label product as \u201cmechanically tenderized\u201d when it was not would be false and misleading. Q7. If we sell mechanically tenderized raw or partially cooked beef or veal products in protective coverings, must the protective coverings meet the mechanical tenderization labeling requirements when the immediate container of this product is labeled \"For Institutional Use Only?\" No. Under 9 CFR 317.1(a)(1), protective coverings should not bear any mandatory labeling information.\u201d In this case, the immediate container, which also serves as the shipping container, is required to be labeled with the descriptive designation and bear validated cooking instructions and all other applicable labeling features. Q8. Is beef cubed steak subject to the new labeling requirements? No, this regulation will not apply to raw or partially cooked beef products that have been cubed. The regulation is specific to needle and blade tenderized beef products. FSIS stated in the final rule: The descriptive designation will only apply to raw or partially cooked beef products that have been needle tenderized or blade-tenderized, including beef products injected with marinade or solution. Other tenderization methods, such as pounding and cubing, change the appearance of the product, putting consumers on notice that the product is not intact. Moreover, most establishments already label cubed products as such. (80 FR 28157) Q9. Must the labels for raw or partially cooked mechanically tenderized beef products be submitted to the FSIS Labeling and Program Delivery Staff (LPDS) for approval? No. The descriptive designations, \u201cmechanically tenderized,\u201d \u201cblade tenderized,\u201d and \u201cneedle tenderized\u201d are not considered special statements or claims under 9 CFR 412.1(c). Therefore, as stated in the final rule, simply adding the descriptive designation and validated cooking instructions to a label would not require LPDS approval, given the label is otherwise in accordance with FSIS\u2019s regulations.", "SUPPLEMENTAL QUESTIONS AND ANSWERS ON DESCRIPTIVE DESIGNATION FOR NEEDLE-OR BLADE - TENDERIZED (MECHANICALLY TENDERIZED) BEEF PRODUCTS Q10. Do the new labeling requirements apply to raw or partially cooked mechanically tenderized beef

products that are produced at establishments that use a validated intervention during the production of such products? Yes, the new labeling requirements would apply to products treated with a validated antimicrobial intervention, unless the establishment applies a lethality treatment that achieves a 5-log reduction in pathogens. Mechanically tenderized beef product treated at an official establishment with an intervention or process, including HPP, that has been validated to achieve at least a 5-log reduction for *Salmonella* and *Shiga Toxin-producing E. coli* (STEC) organisms (including *E. coli* 0157:H7) would not be subject to the requirements in this final rule because it has received a full lethality treatment. (See 80 FR 28153) Q11. Do the new labeling requirements apply to mechanically tenderized beef products labeled or prepared at retail stores? Yes, the new labeling requirements would apply to raw or partially cooked mechanically tenderized beef products produced, packaged, and labeled at a retail store.

Cooking Instructions Q12. Is there compliance guidance available on validating cooking instructions for mechanically tenderized beef products? Yes, at: FSIS Compliance Guideline for Validating Cooking Instructions for Mechanically Tenderized Beef Products Q13. Where can I find scientific studies on validated cooking instructions? Attachment 1 of the above FSIS Compliance Guideline for Validating Cooking Instructions for Mechanically Tenderized Beef Products contains a summary of published scientific support for cooking instructions. Q14. Do the new labeling requirements apply to raw or partially cooked mechanically tenderized beef products that are too thin to practically measure their internal temperature using a food thermometer? No, the new labeling requirements do not apply to raw or partially cooked mechanically tenderized (including through injection with a solution) beef products that are too thin to measure their internal temperature using a food thermometer, such as beef bacon or carne asada. FSIS does not intend to enforce the requirements for these products because they are customarily prepared in a manner that is sufficient to destroy pathogenic bacteria."}, {"file\_name": "FSIS\_GD\_2016\_0017", "title": "Retail Recordkeeping for Establishments and Retail Stores That Grind Raw Beef Products", "num": "FSIS-GD-2016-0017", "id": "35c184f1471a9e0b03179c64e73b598b244ecd07078231dca701c685e621e564", "co

"SUPPLEMENTAL QUESTIONS AND ANSWERS ON DESCRIPTIVE DESIGNATION FOR NEEDLE-OR BLADE - TENDERIZED (MECHANICALLY TENDERIZED) BEEF PRODUCTS Note that the thickness of many food thermometers used by consumers is approximately 1\8\u201d making it difficult to measure the end product temperature of products 1\8\u201d thick or less through use of a thermometer. Q15. Where on the label of raw or partially cooked mechanically tenderized beef products can the validated cooking instructions appear? Validated cooking instructions must appear on the immediate containers of all raw or partially cooked mechanically tenderized beef products destined for household consumers, hotels, restaurants, or similar institutions. These instructions can appear anywhere on the product label. Mechanically Tenderized Beef With Solutions Q16. Must the label of a raw or partially cooked mechanically tenderized beef product that contains added solution also declare the percentage of added solution? Yes. However, there are different options for declaring the total amount of solution added. See 9 CFR 317.2(e)(2). Q17. Do the new labeling requirements apply to raw or partially cooked beef products that have been marinated in a tumbler or vacuum tumbled? The rule only applies to raw or partially cooked beef products that have been mechanically tenderized by needle or blade. This rule does not apply to other processes, such as tumbling or vacuum tumbling, unless the product is also mechanically tenderized by needle or blade."}]

rule.pdf", "type": "pdf", "n\_pages": 3, "word\_count": 1362, "text\_by\_page": ["Questions and Answers related to the Final Rule \u201cRecords To Be Kept by Official Establishments and Retail Stores That Grind Raw Beef Products\u201d Question 1: What raw ground beef products are covered by the Final Rule? Answer: The Final Rule does not apply to specific products. It requires that official establishments or retail stores that grind raw beef keep records concerning their grinding activities. If official establishments have records to show that the product they grind is going to be fully cooked, the record requirements in the Final Rule do not apply. Question 2: For the Final Rule, how is a ground beef lot defined? Answer: Under 9 CFR 320.1(b)(4)(iii), a ground beef lot is defined, for the purpose of raw ground beef recordkeeping, as the amount of ground beef produced during particular dates and times, following clean up and up until the next clean up. All of the information specified in 9 CFR 320.1(b)(4)(i) must be recorded for each raw ground beef production lot, including the identity of supplier(s) and the time when each cleaning of grinding equipment and related food-contact surfaces occurs. This lot definition is separate from FSIS sampling of E. coli O157:H7, where, pending test results, official establishments must define and hold the sampled lot on the basis of microbiological independence from other production lots. FSIS has issued guidance on defining a lot in this context in Directive 10,010.1, Sampling Verification Activities for Shiga Toxin-Producing Escherichia Coli (STEC) in Raw Beef Products, and in the FSIS Compliance Guideline for Controlling Meat and Poultry Products Pending FSIS Test Results. Retailers have the option to hold potentially implicated product when FSIS samples and tests for E. coli O157:H7 as part of its in-commerce surveillance. See Directive 8010.1, Methodology for Conducting In-commerce Surveillance Activities. If a retailer opts to hold product pending receipt of the sampling results, it must similarly show microbiological independence, typically through information related to grinder and food contact surface cleaning and the source materials used. A \u201clot\u201d in this context is not necessarily limited to the ground beef produced between cleanings.

Question 3: If an official establishment or retail store switches source materials but does not do a complete grinder clean up, do the regulations allow the subsequent product to be a separate lot? Answer: No, if the grinding equipment and product contact surfaces are not cleaned, all of the product that came in contact with that equipment since the last clean-up is considered part of the same lot due to the opportunity for cross-contamination. Question 4: For the Final Rule, is a lot defined by the USDA, the official establishment, or the retail store? Answer: For the purpose of the raw ground beef recordkeeping regulation, USDA has defined a lot as the amount of ground raw beef produced during particular dates and times, following clean up and until the next clean-up (9 CFR 320.1(b)(4)(iii)). In accordance with this definition, the actual size of each lot will depend on the production practices of an official establishment or retail store. Question 5: For the Final Rule, must each lot of raw ground beef produced at an official establishment or retail store be from a single supplier? Answer: No, the Final Rule requires that the official establishment or retail store maintain the specified information for each raw ground beef lot that includes \u201cthe establishment numbers of establishments supplying material\u201d and the \u201csupplier lot numbers and production dates\u201d (9 CFR 320.1(b)(4)(i)). The Agency realizes that there may be more than one source supplier for a lot of raw ground beef product produced by the retailer or establishment. Question 6: For the Final Rule, must the grinding log at the retail store contain an individual entry for a customer-requested grind? FSIS OPPD July 12, 2016", "Questions and Answers related to the Final Rule

\u201cRecords To Be Kept by Official Establishments and Retail Stores That Grind Raw Beef Products\u201d Answer: Not necessarily. An additional entry is not needed if the customer-requested product is ground at the same time and from the same supplier production lot as other material being ground. If a retailer grinds materials from a different supplier, or the same supplier but a different production lot or date, it will have to record the customer grind as a separate lot. Question 7: If an official establishment or retail store makes meatloaf, do all the spices and other ingredients, in addition to ground beef components, need to be included in the records? Answer: No, the official establishment or retail store only needs to maintain grinding records for beef ground at the establishment or store. The establishment or store is not required to record the same information for spices and other ingredients used in the raw ground beef product. Question 8: In a facility that houses both a federally-inspected official establishment and a retail store, which FSIS program staff will verify whether the retail store complies with the new recordkeeping requirements for ground beef? Answer: The FSIS Office of Investigations, Enforcement and Audit (OIEA) Compliance Investigators will verify whether the retail store complies with the recordkeeping requirements by following the instructions found in FSIS Directive 8010.1, Methodology for Conducting In-Commerce Surveillance Activities. The in-plant FSIS Office of Field Operations (OFO) Consumer Safety Inspectors will verify whether the official establishment meets the new recordkeeping requirements. Question 9: If the source material used to grind the raw beef product does not contain a readily identifiable lot number, what should be recorded on the grinding record? Answer: If the supplier lot number on the source material is not apparent, FSIS recommends that the official establishment or retail store contact the supplier for the lot number information. If no lot number is available to be recorded at that time, FSIS recommends that the grinder write down any other available supplier or source material information that may facilitate a swifter traceback, such as bar code numbers, invoice numbers, etc. Question 10: What are the penalties for a retail store if the required records are not maintained? What are the penalties for an official establishment if the required records are not maintained? Answer: If a retail store fails to maintain the required records, FSIS personnel may issue a Notice of Warning or in the event of repeated violations, request the Department of Justice to initiate a civil proceeding to enjoin the defendant from further violations of the applicable laws and regulations, or take other action as authorized by law. If FSIS personnel find non-compliance at an official establishment, the Agency could issue noncompliance records (NRs), warning letters, or in the event of repeated violations, refer the matter for additional enforcement actions, as authorized by law. Question 11: If FSIS discovers that the required records are not being maintained by the retail store or official establishment, will FSIS request a recall? Answer: Unless there is reason to believe that there is adulterated or misbranded product in commerce, FSIS will not request that the official establishment or retail store recall the product corresponding to the records that were not maintained. Question 12: Is the use of ditto marks an acceptable way to carry information down to the next line of the grinding log without having to write the information all over again? Answer: Yes, ditto marks may be used as long as the information is identical. FSIS OPPD July 12, 2016", "Questions and Answers related to the Final Rule \u201cRecords To Be Kept by Official Establishments and Retail Stores That Grind Raw Beef Products\u201d Question 13: Besides raw ground beef, does the Final Rule apply to other non-intact raw beef produced by an official establishment or retail store? Answer: No, the rule requires that official establishments or retail stores that grind raw

beef keep records concerning their grinding activities. The final rule does not apply to other activities such as mechanically tenderizing or needle-injecting raw beef. Question 14: If an official establishment or retail store is purchasing ground beef that it portions and repackages, is it required to keep records under this Final Rule? Answer: No, an official establishment or retailer store is not subject to the Final Rule, unless it actually grinds the raw beef. FSIS OPPD July 12, 2016"]}, {"file\_name": "FSIS\_GD\_2017\_0001", "title": "Labeling Policy Guidance - Uncooked, Breaded, Boneless Poultry Products", "num": "FSIS-GD-2017-0001", "id": "7b9772d4463de7b43d923239d631563f82171ffc13932c632fdfbfa7abb110d1", "corp\_us": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/import/Labeling\_Policy\_Guidance\_Uncooked\_Breaded\_Boneless\_Poultry\_Products.pdf", "type": "pdf", "n\_pages": 9, "word\_count": 3537, "text\_by\_page": ["Food Safety and Inspection Service (FSIS) Labeling Policy Guidance Uncooked, Breaded, Boneless Poultry Products Purpose of the Guidance The intent of this document is to provide guidance to the industry on the modifications that are necessary for the labeling of uncooked, breaded (both pre-brown and not prebrowned), boneless poultry products that also may be stuffed or filled, char-marked, or artificially colored, in accordance with the letter to the manufacturers of these types of products posted on the FSIS website on March 20, 2006 (see the following web link:

[http://www.fsis.usda.gov/OPPDE/larc/Policies/Letter\\_to\\_Industry\\_on\\_Frozen\\_Uncooked\\_Poultry.pdf](http://www.fsis.usda.gov/OPPDE/larc/Policies/Letter_to_Industry_on_Frozen_Uncooked_Poultry.pdf)). Products of these types are similar to the products associated with the recall that was posted on the FSIS website on March 10, 2006, involving frozen, stuffed chicken entrees. As explained in the recall notice, the frozen state, labeling, and cooked appearance of the uncooked chicken products may have caused consumers to believe that they were precooked. Thus products may not have been cooked by consumers to a safe internal temperature. FSIS is concerned that the labeling of products of this type be adequate to inform the public of the manner of handling required to maintain the products in a wholesome condition and to prepare them safely. Moreover, the cooking instructions need to be validated to address the intended use by the consumer. While consumers may be directed to cook the products to an internal temperature of 165 degrees Fahrenheit (F), if they are directed to use a cooking method that is not practical or not likely to achieve the necessary level of food safety (e.g., cooking frozen product in a toaster oven or microwave oven), the cooking instructions may not be valid. As a result of the recall, the letter noted above was posted on the FSIS website and sent directly to manufacturers of these products and similar products recommending that labels be modified to emphasize that such products are not cooked. A statement on the principal display panel of the packaging, such as \u201cUncooked: For Safety, Must be Cooked to an Internal Temperature of 165 degrees F as Measured by Use of a Thermometer,\u201d is an appropriate way to help consumers understand the need for the safe preparation of the products on their part. The cooking instructions should also be revised commensurate with validation that lethality is achieved with all the methods of cooking preparation that are declared on the labels. By improving the cooking instructions, as well as documenting that cooking methods are validated as part of the official labeling record, a situation like the one that led to the recent recall could be avoided. Additional guidance was made available in the March 2006 Report of the Subcommittee on Consumer Guidelines for the Safe Cooking of Poultry Products of the National Advisory Committee on Microbiological Criteria for Foods

(NACMCF). This report should serve as a guide on how an establishment can make the necessary modifications to", "product labeling and for cooking method validation such that the subject products can be assured to result in safe and wholesome products, and that the revised labeling is not misleading. The report can be found on the FSIS website at:

[www.fsis.usda.gov/PDF/NACMCF\\_Report\\_Safe\\_Cooking\\_Poultry\\_032406.pdf](http://www.fsis.usda.gov/PDF/NACMCF_Report_Safe_Cooking_Poultry_032406.pdf) I. Suggestions on the Modifications of Affected Labeling Consumer-Packaged Product and Products Directed to Food Preparation Establishments \u2022 The principal display panel of labels should bear prominent and clear terms that convey that the product contains raw or uncooked poultry, i.e., \u201craw,\u201d \u201cuncooked,\u201d or \u201cnot ready to eat.\u201d Based on the recommendations of the NACMCF, the term \u201cready to cook\u201d should not be used unless used in conjunction with a term such as one of those listed above. Consumer-Packaged Product \u2022 Only validated cooking instructions should appear on labeling. The cooking instructions should include, at a minimum, (1) the method of cooking, (2) an endpoint temperature of 165 degrees F or higher, and (3) instruction that the endpoint temperature is measured by use of a thermometer. Products Directed to Food Preparation Establishments \u2022 For food products directed to food preparation establishments, i.e., hotels, restaurants, and institutions (HRI), FSIS will accept references to the Food Code or equivalent State and local requirements as adequately addressing the need for adequate cooking. Because the food preparation establishments have standard operating procedures, e.g., cooking procedures consistent with Food Code or State standards, there is no need for further evidence of validation regarding the cooking instructions. In these instances, a statement of limited use should be applied to the labeling of these products, stating that the product is for preparation at food preparation establishments or specific restaurants. Examples of such statements are \u201cFor preparation by a food preparation establishment,\u201d \u201cfor HRI use only,\u201d or \u201cMade exclusively for XYZ restaurants only.\u201d This statement should appear on the label as well as the label application form. II. Procedures for Submitting Labels for Approval \u2022 Submittals of modified labeling that respond to the March 20 Letter should be submitted to the Agency in the usual manner. Labels may be submitted individually or, to help establishments that may have several labels that need to be modified, label submissions may be presented as a", "\u201cblanket\u201d sketch submissions. A \u201cblanket\u201d sketch submission consists of a completed FSIS Form 7234-1 to which is attached at least one representative label that indicates the proposed modifications, i.e., a prominent statement on the PDP designating the product as raw, uncooked, or not-ready-to-eat, and the planned modifications of the cooking instructions, or a statement of limited use if the product is designated for use at a food preparation establishment, and a listing of all other product labels that will be revised in the same manner (in duplicate). Such blanket sketch submissions are being accepted by the Agency as a means of accommodating manufacturers of the types of products in question when the only changes to the subject labels are those that are the subject of the March 20 Letter. \u2022 The Agency understands that establishments may have existing stocks of labels for the affected products on-hand. Existing stocks can be used by November 1, 2006, without submitting to the Agency for a temporary approval. However, every effort should be made to submit revised labeling to the Agency in accordance with the dates noted below. Dates by Which Labels Need to be Submitted \u2022 All products packaged and labeled for consumer retail purchase, i.e., those sold directly to consumers and prepared by consumers,

should be submitted to the Agency for sketch approval by May 1, 2006, in accordance with the March 20 Letter. \u2022 Manufacturers of products to be prepared by food preparation establishments, such as a hotels, restaurants, or institutions, need to submit a listing of the labels and the planned changes, (i.e., one representative label that includes the terms or statements about being uncooked product and validated cooking instructions or examples of statements of limited use) to the Agency by July 1, 2006. \u2022 FSIS recognizes that labeling for the subject products that bear Child Nutrition (CN) statements must be submitted directly to the Food and Nutrition Service (FNS) for evaluation prior to submission to FSIS. Because such labels cannot be submitted as a blanket approval, individual label submittals must be prepared. For that reason, labels for the subject products that bear CN statements must be submitted to FNS by June 1, 2006. After the labels have been evaluated by FNS, they need to be sent to FSIS for sketch approval. \u2022 All labels (i.e., for consumer packaged retail products, products for food preparation establishments, and products bearing CN statements) that have been sketch-approved by FSIS (either through a blanket approval or individual label approvals) should be in final form no later than September 30, 2006." ,\u2022 The Office of Field Operations (OFO) will not be taking enforcement action on the labeling changes expected to be initiated by May 1, 2006, until FSIS issues specific verification procedures in an FSIS Notice expected in early September 2006. Meanwhile, FSIS will convey the labeling implementation strategy to the District Offices, who will inform field personnel about the implementation strategy. **QUESTIONS AND ANSWERS CONCERNING THE REVISION OF LABELING OF UNCOOKED, BREADED, BONELESS, POULTRY PRODUCTS THAT MAY BE STUFFED OR FILLED, CHARMARKED OR ARTIFICIALLY COLORED**

1. Will all types of products need the label changes described in the March 20, 2006 letter to industry concerning uncooked breaded, poultry products that is posted on FSIS website? The types of products include uncooked, raw or not ready to eat, breaded (both pre-brown and not pre-brown), boneless poultry products that also may be stuffed or filled, char-marked, or artificially colored. The frozen state, labeling, and cooked appearance of these uncooked poultry products may cause consumers to believe that they are ready to eat. Examples of such products include but are not limited to: breaded chicken patties, breaded, pre-brown, chicken cordon bleu, chicken Kiev, chicken stuffed with broccoli and cheese, turkey patties, and chicken nuggets.

2. Does this action apply to both refrigerated and frozen products? Yes, the food safety concern regarding the adequacy of the labeling for uncooked, raw or not ready to eat, breaded, boneless poultry products that also may be stuffed or filled, charmarked, or artificially colored, exists whether the product is frozen or refrigerated.

3. Will the labels for single ingredient products, such as leg quarters, drumsticks, chicken wings, or other whole muscle products, or poultry products with added solution but no breading, that have a cooked appearance, need to be revised? The products to which the March 20, Letter relates are frozen or refrigerated, breaded, boneless not-ready-to-eat poultry with a cooked appearance. If a product is other than breaded, boneless not-ready-to-eat poultry, the Letter does not apply. However, if the product is not-ready-toeat and has a cooked appearance or it is not obvious that the product is raw, the product should bear special labeling alerting the user that the product is not-ready-to-eat. The labeling should bear safe handling instructions if the poultry component is not ready to eat; a prominent statement on principal display panel indicating product is not-ready-to-eat, e.g., \u201cCook thoroughly\u201d or \u201cRaw,\u201d validated cooking instructions that have been shown to be understood by

the food preparers and that are sufficient to destroy", "pathogens to result in a microbiologically safe product and if nutrition facts are present, the serving size should be based on the ready to cook reference amount customarily consumed (9 CFR 381.412). 4. Why do the labels for the products described above need to be revised? FSIS is concerned that the labeling of products of this type should be revised to adequately inform consumers and food preparers about the uncooked nature of the products and of the manner of handling required to maintain the products in a wholesome condition and to prepare them safely; i.e., provide a lethal heating step to achieve a microbiologically safe product. 5. Why does FSIS want to take this action so quickly? It is clear from the recent events that labels for uncooked, breaded, boneless poultry products on the market today may not be understood or followed by consumers. This lack of understanding may result in consumers not cooking the products to the minimum internal temperature (165 degrees F) necessary for the destruction of foodborne bacteria and viruses, even though the cooking instructions on the product labeling tell them to do so. 6. Does this guidance only affect the labeling of retail product labels or are all product labels of the type described above, even those destined for food preparation establishments such as hotel, restaurants and institutions, as defined by the Food Code, need to be revised? No, there is no distinction between the labeling needed for consumer packaged retail products; and food preparation establishments, such as hotels, restaurants or institutions or other food preparers, because the same food safety concerns exist. 7. If an official establishment is selling its uncooked or not-ready-to-eat breaded, boneless, poultry product to a food preparation establishment that already has specific cooking instructions for that product, is it necessary that cooking instructions be added to the label? It depends on whether the product has the potential of being released into commerce. If a federal establishment can ensure that given the circumstances of its relationship with a food preparation establishment and there is no real chance of the product getting into commerce, the Agency will consider whether or not the cooking instructions for that product are necessary. In all cases, a specific statement of limited use, e.g., "\u201cFor preparation by a food preparation establishment only, according to the food code or equivalent; \u201d \u201cPrepared exclusively for XYZ Restaurants; \u201d or \u201cFor HRI use only,\u201d will be required to ensure the product is confined to the food preparation industry only." 8. What types of terms or statements should be included when revising labels for uncooked breaded, boneless poultry product labels to convey to consumers that these products are not ready to eat? Although the statement in the Letter to Industry, i.e., "\u201cUncooked: For Safety, Must be Cooked to an Internal Temperature of 165 degrees F as Measured by a Thermometer\u201d clearly conveys that the product is not-ready-to-eat and needs to be cooked before it can be safely consumed, other statements may be used on the principal display panel as well. The three key elements for an effective statement are: (1) terms that reflect that the product is not ready to eat, for example, \u201cUncooked,\u201d \u201cRaw,\u201d \u201cRaw - Cook Thoroughly,\u201d \u201cSee Cooking Instructions;\u201d (2) a specific endpoint internal temperature, i.e., 165 degrees F or higher; and (3) a direction to measure the endpoint safe minimum temperature by a food thermometer. Statements that include these three key elements need to appear on the principal display panel of consumer packaged products in order to give consumers consistent and prominent information about the nature of the product. 9. Where does the statement that will convey that the product is uncooked or partially cooked need to appear on the label? Such

statements need to appear on the principal display panel of the product label. The principal display panel of the package should be the focal point for certain safety information to make it clear that the product is not ready to eat. 10. When do affected establishments need to submit revised labels to the Agency? Establishments need to submit labeling for consumer packaged retail products by May 1, 2006. Products prepared for food preparation establishments (not sold directly to the consumer) need to submit by July 1, 2006. For labels bearing a child nutrition (CN) statement, labeling must be submitted to the Food Nutrition Service (FNS) by June 1, 2006, and then subsequently sent for approval by FSIS. 11. Why do CN labels have a different deadline date for submission of revised labeling? That is because labels bearing CN statements require evaluation by FNS for each label submitted. FNS needs adequate time to handle the expected increase in label rescissions, requests for temporary approval and new label submissions. The extended date for submitting such labeling to FNS is June 1, 2006. The date by which modified labels need final label approval is September 30, 2006. Labels for FNS evaluation should be directed to USDA, FNS, CND, 3101 Park Center Drive, Alexandria, VA 22302, Attn: CN Label Reviewer, Phone: 703-305-2609". 12. If a company believes that its current labeling is sufficient to meet the criteria in the March 20 Letter, do they need to resubmit their labels to the Agency by one of the dates cited above? Yes, if a company has reevaluated their current labeling and feels that it is sufficient to inform the consumer that cooking is required for safety (and the cooking instructions are validated), then they should resubmit their labeling to the Agency for consideration of sketch approval. In other words, establishments cannot self-determine that the labeling is sufficient. 13. We have several labels that need to be revised according to the March 20, 2006, letter. Do we need to submit each label separately? Establishments do not need to send in every label in for sketch approval by the dates mentioned above. Establishments can submit a \u201cblanket\u201d sketch approval indicating the modifications they intend to make to the labels of products that are the subject of the letter. An example of one of the products with the proposed changes would need to be submitted attached to a completed FSIS Form 7234-1 (in duplicate). 14. Why are labels for products bearing CN statements excluded from blanket approvals? A blanket request is a label application for multiple label approvals sharing the same problem. All CN labels with proper documentation must be submitted to FNS prior to submission to FSIS. Acceptable label applications for FSIS evaluation contain a FNS sign-off. In order to remind industry of the proper label approval procedure for CN labels, a statement will be placed on all blanket requests indicating that CN labels are excluded and will also indicate that all CN labels must be submitted through FNS prior to submission to FSIS, LCPS. Labels for FNS evaluation should be directed to USDA, FNS, CND, 3101 Park Center Drive, Alexandria, VA 22302, Attn: CN Label Reviewer, Phone: 703-305-2609. 15. Our establishment is prepared to make the necessary changes to its labeling; however, we have several hundreds of label on-hand. Will we need to get temporary approval on existing inventory of labels? The Agency understands that establishments may have existing stocks of labels on hand. Existing stocks must be used by November 1, 2006, without submitting for a temporary approval. 16. Can a pressure sensitive sticker that includes the necessary terms be used to update labels?", "If a pressure sensitive sticker is used to modify current labeling, the sticker must be submitted for evaluation, as well. Once approved, the pressure sensitive sticker policy guidance on the FSIS website would be in effect; all existing stocks bearing a sticker with acceptable terminology may be used until stocks are exhausted.

17. Will my inspector take action against my labeling associated with this issue after May 1, 2006? The Office of Field Operations has been informed of the issue and will not take enforcement action on this issue until the Agency provides verification procedures through an FSIS Notice. It is anticipated that FSIS will publish an FSIS Notice in early September 2006, in order to ensure that labels are modified and applied to new production after November 1, 2006.

18. Does the statement of limited use that a food preparation establishment adds to labeling in lieu of cooking instructions need to be on the principal display panel? No, the statement of limited use does not need to appear on the principal display panel but may appear in a prominent manner anywhere on the label.

19. Do the cooking instructions need to be on the principal display panel (PDP)? No, the cooking instructions may appear anywhere on the label. However, on consumer packaged products, the endpoint internal temperature and the need to measure the endpoint internal temperature by use of a food thermometer need to appear on the principal display panel.

20. Is it necessary to revise the cooking instructions on uncooked, breaded, boneless poultry products if it does not include the internal temperature of 165 degrees F? Yes, as recommended by the NACMCF, a single minimum internal temperature of 165 degrees F for cooking without time limitation will ensure that the cooked poultry product is microbiologically safe. This temperature will destroy Salmonella, the most heat resistant pathogen of public health concern in raw poultry.

21. Why do the cooking instructions on these uncooked, breaded, boneless, poultry products need to be validated? Cooking instructions need to be validated to ensure that the method by which the product is prepared is adequate to achieve the lethality of any pathogens that may be present in a raw product. When validating the cooking instructions establishments should take into account how the consumer is likely to interpret the cooking instructions and what the consumer may actually do in preparing and cooking the product.

22. How can I assure FSIS that the cooking instructions have been validated? Does the validation data need to be included with the label submittal? Validation data should be included as part of the official labeling record for the product.

23. Why is it necessary to include cooking instructions on the label if the statement on the principal display panel includes both an endpoint temperature and the need to measure the temperature with a meat thermometer; e.g., \u201cUncooked: For Safety, Must be Cooked to an Internal Temperature of 165 degrees F as Measured by Use of a Thermometer\u201d The cooking method by which the endpoint temperature is achieved needs to be included on the label in the cooking instructions because the consumer needs explicit information about the way to achieve a safe product for consumption.

24. If the statement on the PDP includes an internal temperature and the use of a thermometer to measure the temperature; does this information need to be included in the cooking instructions as well? Yes, the endpoint temperature and the need for a thermometer to ensure that the endpoint temperature is met, should also be included in the cooking instructions would further emphasize that 165 degrees F is necessary to achieve a microbiological safe product using the method described in the cooking instructions.]}, {"file\_name": "FSIS\_GD\_2017\_0012", "title": "Guideline on Whole Grain Statements on the Labeling of Meat and Poultry Products", "num": "FSIS-GD-2017-0012", "id": "becac3a3fd520f7374a5004f460e400eba271169390bad89965cd0b3733dc580", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/import/Guideline-Whole-Grain-Statements-"}]

15", "3 Preface What is the purpose of this compliance guideline? The purpose of this compliance guideline is to help industry determine which whole grain statements are permitted on meat and poultry products and the criteria for their use. The Food Safety and Inspection Service (FSIS) is the agency in the United States Department of Agriculture (USDA) with the responsibility for assuring that the labeling of meat, poultry and egg products is truthful and not misleading. Labeling bearing any reference to whole grains is a special statement. All labels bearing special statements or claims must be sent to the Agency\u2019s Labeling and Program Delivery Staff (LPDS) for evaluation and approval before use according to the Code of Federal Regulations (CFR) Title 9 Section 412.1. However, once a label with a statement on whole grains is approved, there are many types of changes to the label that do not require submission to the Agency prior to use and can be generically approved (e.g., change in net weight, label color, vignettes, cooking instructions, and the addition of information that is not considered a special statement or claim). The key for making the change \u201cgenerically\u201d is that the change cannot affect the special statement or claim. Slide 40 of the Generic Label Approval PowerPoint Presentation from the link below provides an example of a special claim.

<http://www.fsis.usda.gov/wps/wcm/connect/1364c48d-214b-41bf-bab86289f951cb31/Generic-Final-Rule-Overview-Industry.pdf?MOD=AJPERES>. Who is this guideline designed for? This guideline is for establishments that are designing or modifying meat or poultry product labels with statements related to whole grains. What changes have been made to the guideline from the last version? FSIS previously issued guideline on whole grains claims in October 2005. This previous version was focused on references to

USDA\u2019s MyPyramid. FSIS has updated the guideline to include further details and explanations on the different types of claims and a key-points reference chart. How can I comment on this guideline? FSIS is seeking comments on this guideline as part of its efforts to continuously assess and improve the effectiveness of policy documents. All interested persons may submit comments regarding any aspect of this document, including but not limited to: content, readability, applicability, and accessibility. The comment period will be 60 days and the Agency will update the document in response to the comments. Comments may be submitted by either of the following methods:","4 Federal eRulemaking Portal Online submission at regulations.gov: This Web site provides the ability to type short comments directly into the comment field on this Web page or attach a file for lengthier comments. Go to <http://www.regulations.gov> and follow the online instructions at that site for submitting comments. Mail, including - CD-ROMs, and hand- or courier-delivered items: Send to: Docket Clerk U.S. Department of Agriculture (USDA), FSIS, Patriots Plaza 3 1400 Independence Avenue SW, Mailstop 3782, 8-163A Washington, DC 20250-3700. All items submitted by mail or e-mail must include the Agency name, FSIS, and document title: Food Safety and Inspection Service Guideline on Whole Grain Statements on the Labeling of Meat and Poultry Products October 2017. Comments received will be made available for public inspection and posted without change, including any personal information, to <http://www.regulations.gov>. Although FSIS is requesting comments on the guideline and may update it in response to comments, the guideline reflects FSIS\u2019s current position, and establishments may start using it now. What if I still have questions after I read this guideline? If the desired information cannot be found within the Compliance Guideline, FSIS recommends that users search the publicly posted Questions & Answers (Q&As) in the askFSIS database or submit questions through askFSIS. Documenting the questions helps FSIS improve and refine present and future versions of the Compliance Guideline and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter FSIS Interim Policy Guide on Whole Grain Claims Question Field: Enter question with as much detail as possible Product Field: Select Labeling from the drop-down menu Category Field: Select Labeling Regulations, Policies & Claims from the drop-down menu Policy Arena: Select Domestic (U.S.) only from the drop-down menu When all fields are complete, press Continue.","5 BACKGROUND Since a petition was submitted in 2004 to the Food and Drug Administration (FDA) regarding the uses of Whole Grain Descriptive Claims, the use of these statements has increased and diversified. Companies have shown interest in making claims such as: \u201cwhole wheat pasta.\u201d For that reason, this guideline aims to help the meat and poultry industry determine which claims are permitted on the labeling of their products. GENERAL WHOLE GRAIN STATEMENTS The Agency will allow, with LPDS sketch approval, factual statements and certain whole grain claims provided the statements\claims do not conflict with FSIS regulations and are not false or misleading. Factual statements simply state the level of a grain component in a serving of the product, e.g., 10 grams whole grain per serving. FSIS will also allow certain claims that do not expressly state or imply a specific level of whole grains through sketch approval, e.g., \u201cmade with 100% whole grain brown rice\u201d or the label has a product name declaring a whole grain, e.g., \u201cwhole wheat pepperoni pizza.\u201d NOTE: See Label Example 1 for a factual statement representation The basis for all whole grain factual statements and claims is that the product contains a minimal

quantity of the specified whole grain component. FSIS considers these statements to be false or misleading if the product does not contain at least 8 grams of dry whole grain ingredient per labeled serving size of the meat or poultry product as declared in the nutrition facts panel on the label and per the appropriate Reference Amount Customarily Consumed (RACC) for the meat or poultry product (9 CFR 317.312 Table 2 or 381.412 Table 2). Labeling for institutional use products that are exempt from including the nutrition facts panel may make whole grain statements or claims but the labeling application that needs to be submitted to FSIS will still need to show that the product meets the 8 gram minimum requirement per recommended serving size and per the appropriate RACC. FDA STANDARDIZED WHOLE GRAIN PRODUCTS When a claim specifies the product component that contains the whole grain, for example, \u201cmade with whole wheat spaghetti\u201d or \u201cpepperoni pizza made with whole grain crust,\u201d the whole grain component apart from the total meat or poultry product will need to meet an additional requirement which will be determined based on the standards of identity for whole grain products in 21 CFR 139.138. Products that have a whole grain standard of identity in 21 CFR must meet the FDA standard in order to use that product name, for example, in order to make the claim \u201cmade with whole wheat spaghetti\u201d the whole wheat spaghetti must meet the FDA standard of identity in 21 CFR 139.138, which requires 100% of the grain used to make the spaghetti be whole wheat." 6 SPECIFYING THE COMPONENT THAT CONTAINS WHOLE GRAIN When the component identified in the claim does not have a standard of identity for the whole grain product in 21 CFR, for example, there is no FDA standard for \u201cwhole wheat pizza crust\u201d or \u201cwhole wheat tortillas,\u201d then FSIS requires that whole grains make up at least 51% of the total dry grain used to formulate the non-standard grain product. CALCULATION EXAMPLES In order to obtain label approval, the label application form should provide calculations to support and verify that the product meets the above requirements. The calculations provided will need to correspond to the formula provided for the particular product. Because the calculations will vary depending on the statement or claim made and the nature of the formulation, below are several examples of the calculations that could be acceptable with a label application: A. Example calculations for a factual statement, such as, \u201cmade with whole grains\u201d which needs to show a minimum of 8g whole grain per labeled serving size as provided in the nutrition facts panel, and a minimum of 8 grams whole grains per RACC: Serving size of meat or poultry product in grams \u00d7 % dry whole grains in total formula = grams whole grains per serving (must be 8 grams or higher) AND RACC in grams for the meat or poultry product \u00d7 % dry whole wheat in total formula = grams whole wheat per RACC (must be 8 grams or higher) B. Example calculations for a factual statement, such as, \u201c10 grams whole wheat per serving,\u201d which needs to show a minimum of 10 grams of whole wheat per labeled serving size as provided in the nutrition facts panel, and a minimum of 10 grams whole wheat per RACC: Serving size of meat or poultry product in grams \u00d7 % dry whole wheat in total formula = grams whole wheat per serving (must be 10 grams or higher) AND RACC in grams for the meat or poultry product \u00d7 % dry whole wheat in total formula = grams whole wheat per RACC (must be 10 grams or higher) C. Example calculations for a \u201cpepperoni pizza made with whole grain crust\u201d that requires 8 grams or more whole grain per labeled serving size as provided in the nutrition facts panel, 8", "7 grams or more whole grain per RACC, and a minimum of 51% dry whole grain in the total dry grain used to make the crust: Serving size of

pizza in grams \u00d7 % crust \u00d7 % whole grain in the crust = grams of whole grain per serving (must be 8 grams or higher) AND RACC in grams for the meat or poultry product \u00d7 % crust \u00d7 % whole grain in the crust = grams of whole grain per RACC (must be 8 grams or higher) AND (Grams of whole grain in the crust \u00f7 grams of total grain in the crust) \u00d7 100 = % of whole grain in the grain component (must be 51% or higher) When the whole grain factual statements and claims meet the outlined requirements above, such statements and claims may be declared on any panel of the labeling of meat and poultry products. Declaring a whole grain component in the ingredients statement alone is not considered a claim and does not need to meet the 8 grams criteria but it should still meet the 51% criteria (or 100% criteria if there is a FDA standard). For example, if the product name is \u201cpepperoni pizza\u201d and the ingredients statement declares \u201cwhole wheat crust\u201d then the crust should be at least 51% whole wheat of the total grain component in the crust. This is because there is no FDA standard for whole wheat crust and the product does not need to meet the 8 grams criteria per labeled serving size or per RACC. LEVEL CHARACTERIZATION The nutrition labeling regulations in 9 CFR 317.313(b) and 381.413(b) clearly state that claims that, expressly or by implication, characterize the level of a nutrient may not be made on the labeling of a meat or poultry product unless the claim is made in accordance with the nutrition labeling regulations. The FSIS nutrition regulations do not include provisions to make claims about whole grains, whole grain cannot be included within the nutrition facts panel as a nutrient, and there is no regulatory percent Daily Value for whole grains. Therefore, claims such as \u201cgood source of whole grains,\u201d and \u201cexcellent source of whole grains\u201d are not permitted on meat and poultry product labeling. FSIS regulations in 9 CFR 317.313 and 381.143 do not allow statements or claims that imply that the level of whole grains in a product is high, or places significance on a specific level of whole", "8 grains, including, but not limited to:

\u201cccontains X grams of whole grains,\u201d \u201cmore than X grams of whole grains,\u201d \u201cat least X grams whole grains\u201d and \u201cfortified with X grams of whole grains.\u201d COMPANY NAMES or BRAND NAMES Trademarked company or brand names that name or imply a level of whole grain in a product cannot be approved when given prominence on the label. One exception is that a company or brand name that includes a whole grain claim or implies a whole grain claim may be part of the signature line as required by 9 CFR 317.2(g) and 381.122 provided that the signature line is normally placed, for example, in normal size font at the bottom of the information panel, and is not given undue prominence which would cause the use of the company name to be a false or misleading claim. AD-COPY FSIS needs to review and approve ad-copy as labeling and the above mentioned statements and claims criteria will be applied. Ad-copy may make general statements about whole grains provided it does not make a specific claim or relate to specific health benefits, for example, the statement, \u201cinclude whole grains as part of your daily life\u201d provides general nutrition advice without making a specific unapproved claim and would be acceptable on labeling through LPDS sketch approval, but a statement such as, \u201cwhole grains are chock full of nutrients\u201d is making a claim about whole grains which is undefined and not permitted. TRADEMARKED SYMBOLS Trademarked company or brand names, trademarked symbols or phrases, and statements used in ad-copy on labeling that name or imply a level of whole grain in a product cannot be approved. Certain non-specific trademarked symbols may be eligible to include on labeling of meat and poultry products provided the product provides a

minimum of 8 grams whole grain (or specific grain) per serving and per RACC for the product and obtains LPDS sketch approval. Trademarked company or brand names, trademarked symbols or phrases, and statements associated with whole grains are evaluated in the context of the label on which it is used. Just because a symbol is trademarked does not mean it can be added to labeling if it creates a false or misleading statement or claim about the product.

USDA\u2019s CHOOSE MY PLATE The Choose MyPlate: The USDA MyPyramid program was replaced by USDA\u2019s Choose MyPlate in 2011. Thus, companies referencing MyPyramid on labeling will need to revise such labeling to eliminate the outdated references. USDA\u2019s Center for Nutrition Policy and Promotion (CNPP) provides guidance to companies if they wish to include Choose MyPlate on labeling. Including Choose MyPlate on labeling is a special claim that requires LPDS sketch approval. Contact CNPP for questions about Choose MyPlate: <http://www.choosemyplate.gov/>, "9 Choose MyPlate Whole Grain Food Group Statements Statements declaring the amount of a food group or food sub-group that a product contributes as it relates to the 2015-2020 Dietary Guidelines for Americans (DGA) recommendations are considered special claims that require LPDS sketch approval. In order to make such statements, the product should be in compliance with CNPP, who, on their MyPlate Style Guide and Conditions of Use for the Icon , states that the use of whole grain content calculations based on MyPlate will only be granted on the labeling of meat and poultry products that: 1) Meet the criteria for \u201chealthy\u201d as defined by USDA and FDA in 9 CFR 317.363(d) and 381.463(d), and 21 CFR 101.65(d)(2), respectively; and 2) Contain little or no added sugars. Statements that FSIS would approve include: \u201cOne whole grain ounce equivalent per serving, MyPlate recommends at least 3 one-ounce equivalents of whole grains per day,\u201d and \u201cWhole Grains = 2 one-ounce equivalents\* \*MyPlate recommends at least 3 one-ounce equivalents of whole grains per day.\u201d Moreover, in order to not be viewed as misleading, the label that bears the claim must provide an adequate explanation for the consumer, for example, include content calculations, or references, based on a 2,000 calorie diet, and specify that the information is based on MyPlate recommendations. In addition, FSIS asks for the following to be taken into account when making this kind of statements: 1) Ounce equivalents of whole grain may be declared by half or whole numbers and should be declared as \u201counce equivalents\u201d in harmony with the language found in MyPlate; 2) Ounce equivalents may not be rounded up to the nearest half or whole ounce, but products should contain at least the amount declared by any claim or information; and 3) Calculations of the amount of whole grain ingredient or ounce equivalent must be provided with the label for sketch approval when statements are made regarding ounce equivalents of whole grains. To calculate whole grain ounce equivalents: <http://www.choosemyplate.gov/grains> MULTI-GRAIN Because the claim \u201cmulti-grain\u201d is not specifically a \u201cwhole grain\u201d claim, FSIS permits the use of \u201cmulti-grain\u201d when the product includes more than one grain source without the need to submit the label for review and approval prior to its use. For example, if the label declared a product name as \u201cmulti-grain pepperoni pizza\u201d and the ingredients statement showed that the crust was made with two or more different grains (whole grain or not whole grain when derived","10 from different grains), then no further documentation is needed to support the claim \u201cmultigrain.\u201d GRAINS CONSIDERED WHOLE GRAINS Examples of grains that are commonly considered a whole grain by the Whole Grains Council or FDA can be found below. - Amaranth - Unhulled barley -

Buckwheat - Whole kernel corn (including popcorn) - Millet - Oats (including rolled, quick and steel cut varieties) - Quinoa - Brown rice (including wild varieties) - Sorghum - Teff - Triticale - Whole wheat (including Kamut and other varieties) Legumes and oilseeds such as: soy, chickpeas, flax seeds, chia and sunflower seeds are not considered whole grains. Lastly, any labeling sketches granted approval with references to whole grains that are not in compliance with this policy should be brought into compliance with this policy. Consistent with the Agency's regulations about generic label approval, labels bearing special statements, such as those described above, must be submitted to LPDS for evaluation and approval before use for compliance with 9 CFR 412.1. However, once a label is approved with a whole grains statement or claim, additional changes may be made to the label such as to the brand name, net weight, handling statement, ad copy, and label design. These types of changes to the previously approved label are generically approved under 9 CFR 412.2 because they do not affect the special statement or claim. For additional information about FSIS labeling policies and programs, review the FSIS website for labeling at:

<http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatorycompliance/labeling/> or contact the LPDS at (301) 504-0878 or (301) 504-0879.,"11 Label Example 1 [Back to reading],"12 KEY-POINTS REFERENCE CHART Claim Type Permitted Examples Criteria and Requirements1 for Approval GENERAL STATEMENTS Yes (requires FSIS approval under 9 CFR 412.1) - \u201cWhole Wheat Pepperoni Pizza\u201d - \u201cX grams of whole grain per serving\u201d 1) A minimum of 8 grams of dry whole grain per both labeled serving size and Reference Amount Customarily Consumed (RACC) for the product; 2) Demonstrate that \u201cX\u201d grams per serving size is accurate when specifying the amount; plus 3) Provide calculations for points 1 and/or 2 according to claim. FDA STANDARDIZED WHOLE WHEAT PRODUCTS Yes (requires FSIS approval under 9 CFR 412.1) - \u201cWhole Wheat Spaghetti and Meatballs\u201d 1) A minimum of 8 grams of dry whole grain per both, labeled serving size and RACC for the product; 2) Grain portion of the product needs to be 100% whole wheat; plus 3) Provide calculations for points 1 and 2 (based on 21 CFR 139.138). SPECIFYING THE COMPONENT THAT CONTAINS WHOLE GRAIN Yes (requires FSIS approval under 9 CFR 412.1) - \u201cPepperoni Pizza with Whole Grain Crust\u201d - \u201cWhole Grain Breaded Chicken Patty\u201d - \u201cMade with Whole Grain Brown Rice\u201d 1) A minimum of 8 grams of dry whole grain per both labeled serving size and RACC for the product; 2) At least 51% of the grain components are whole grain; plus 3) Provide calculations for points 1 and 2. LEVEL CHARACTERIZATION No - \u201cGood Source of Whole Grains\u201d These statements are not permitted because there are 1 The basis for all whole grain factual statements and claims is that there should be a significant amount of the specified whole grain component in the product. FSIS considers these statements to be false or misleading if the product does not contain at least 8 grams of dry whole grain ingredient per labeled serving size of the meat or poultry product as declared in the nutrition facts panel on the label and per the appropriate Reference Amount Customarily Consumed (RACC)" "13 - \u201cMore than X grams \u201d Contains X grams \u201d At least X grams \u201d Fortified with X grams of Whole Grains\u201d no defined claims for whole grains. COMPANY\BRAND NAMES (Trademarked company\brand name associated with whole grains) Yes (in signature line only; requires FSIS approval under 9 CFR 412.1) - \u201cWhole Grain Company\u201d The name of the packer, manufacturer, or distributor (i.e., the signature line) is normally placed at bottom of information panel; not given undue

prominence. AD COPY and TRADEMARKED SYMBOLS (Ad-Copy, Trademarked symbols associated with whole grains in the context of the label on which it is used) Yes (requires FSIS approval under 9 CFR 412.1) - \u201cInclude whole grains as part of your daily life\u201d Evaluated on a case by case basis; documentation would be required if found to be a claim.

WHOLE GRAIN COUNCIL Yes (requires FSIS approval under 9 CFR 412.1) - 1) A minimum of 8 grams of dry whole grain per both labeled serving size and RACC for the product; 2) Demonstrate that \u201cX\u201d grams per serving size is accurate when specifying an amount different from 8 grams; 3) Cannot state \u201cor more,\u201d because it implies level characterization; 4) Cannot state \u201ceat 48 grams or more whole grain daily,\u201d because there is no Daily Reference Value in the nutrition regulation for whole grains; plus; 5) Provide calculations for points 1 and\or 2. USDA\u2019s CHOOSE MY Yes (requires - Including the 1) Not to be used with what", "14 PLATE FSIS approval under 9 CFR 412.1) USDA Choose MyPlate on label or how much to eat, plus 2) Use with \u201cLearn about healthy eating at ChooseMyPlate.gov\u201d MY PLATE WHOLE GRAIN FOOD GROUP STATEMENTS Yes (requires FSIS approval under 9 CFR 412.1) - \u201cOne whole grain ounce equivalent per serving, MyPlate recommends at least 3-one ounce equivalents of whole grain per day\u201d 1) Meets \u201chealthy\u201d; 2) Contains little or no added sugars; 3) Keep separate from Choose MyPlate; plus 4) Calculations for whole grain ounce equivalents (contact CNPP for methodology)", "15 <http://askfsis.custhelp.com/> FSIS\USDA www.fsis.usda.gov 2017"]}, {"file\_name": "FSIS\_GD\_2018\_0001", "title": "Data Samples and Guidelines for Using the Partner Government Agency (PGA) Message Set for Electronic Completion of the U.S. Department of Agriculture (USDA), Food Safety Inspection Service (FSIS) Application for Import Inspection (FSIS Form 9540-1)", "num": "FSIS-GD-2018-0001", "id": "03278adc38bfe07132d74b4dd9deb28dbf8cc0696841f8d9a3741618d0e45f3c", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/import/Data\_Samples\_Guidelines\_PGA\_Message\_Set.pdf", "type": "pdf", "n\_pages": 51, "word\_count": 13423, "text\_by\_page": ["Data Samples and Guidelines for Using the Partner Government Agency (PGA) Message Set for Electronic Completion of the U.S. Department of Agriculture (USDA), Food Safety Inspection Service (FSIS) Application for Import Inspection (FSIS Form 9540-1) Version 3, February 2018", "Summary of Changes \u2022 This revision provides new codes in the PG10 record to accommodate the electronic submission of data required for Siluriformes fish and fish products. \u2022 This revision also clarifies data input instructions in the PG19, PG25 and PG30 records. Document Summary This document is intended as a supplemental guide to the United States Department of Agriculture\u2019s (USDA) Food Safety and Inspection Service (FSIS) data requirements when an Automated Broker Interface (ABI) filer (broker or self-filing importer) is using the Automated Commercial Environment (ACE) System of Customs and Border Protection (CBP) to provide PGA Message Set data. Specifically this guidance covers the data to be provided when a filer is submitting an Entry Summary certified for Cargo Release for products regulated by FSIS. The CBP Customs and Trade Automated Interface Requirements (CATAIR) chapters and appendices can be found on CBP.gov at: <http://www.cbp.gov/document/guidance/pga-message-set> The PGA Message Set and its related Appendix PGA can be found on CBP.gov at: <http://search.usa.gov/search?query=pga+message+set&affiliate=cbpgov> Other related"]}

appendices that could be used when submitting an entry can be found at:

<http://search.usa.gov/search?utf8=%E2%9C%93&affiliate=cbpgov&query=appendix+b> It should be noted that the PGA Message Set does not stand alone and must be submitted with an entry filing (i.e. ACE Entry Summary certified for cargo release (AE)). The Entry Summary contains certain data elements that are common to both FSIS and CBP requirements. The PGA Message Set data requirements for FSIS will not duplicate those common data elements, but rather provide the additional data needed to complete the FSIS application for import inspection (FSIS Form 9540-1) electronically. This guidance provides data samples of frequently imported products. The samples include a grid and accompanying text. The grid represents the 80-character limit, per record, allowed by ABI. The PGA Message Set defines the character length, class and position required by ABI for transmission to CBP and the grid shows how the data would be represented in ABI. 1", "FSIS Overview FSIS is the public health regulatory agency responsible for ensuring that domestic and imported meat, poultry, and processed egg products are safe, wholesome, and correctly labeled and packaged. Through the 2008 and 2014 Farm Bills, FSIS now inspects Siluriformes, including catfish, under the Federal Meat Inspection Act. FSIS ensures that meat, poultry, egg products, and Siluriformes imported to the United States originate from eligible countries and are produced under standards equivalent to U.S. inspection standards. In order to enhance the Agency's ability to protect public health, FSIS has launched the Public Health Information System (PHIS) as part of its effort to collect, consolidate, and analyze data. The PHIS interface with ACE enables seamless transfer of data required for the application for FSIS import inspection in advance of the shipment arrival. The inclusion of the data in the PGA Message Set eliminates the need to submit a paper copy of FSIS Form 9540-1 eliminates the manual data entry by FSIS inspection personnel and thereby, expedites the clearance of FSIS regulated shipments. All shipments of meat, poultry, egg products, and Siluriformes (including catfish) imported to the United States must be presented to FSIS at an official import inspection establishment for reinspection prior to release into commerce in the United States. Eligibility of the foreign country, foreign establishment, and product will be determined by the PHIS when the Importer of Record or U.S. Customs Broker files the mandatory application for FSIS import inspection. FSIS ensures that the exporting country\u2019s inspection certificates are authentic and accurate, and when assigned by the PHIS, FSIS performs a more in-depth reinspection of product, including product examination and laboratory testing for pathogens and chemical residues. FSIS sampling is allocated by country, process category, product category, product group, and species and the inspection results are entered into the PHIS. If the shipment fails reinspection, the noncompliant product is refused entry and the rate of inspection is intensified to ensure product compliance of subsequent shipments. FSIS PGA Message Set \u2013 FSIS Electronic Application (FSIS Form 9540-1) Data Requirements Below is the set of data elements FSIS requires from the trade, depending on the commodity and depending on whether electronic certification (government-to-government eCert) is applicable. Required PG Records for eCert Country (Currently Australia, New Zealand, and the Netherlands) PG Record Description OI Commercial Description PG01 Government Agency Code, PGA Line Number, Supplemental Product Codes (if applicable) PG02 Always P for Product PG06 Process Country, Source Country (if applicable) 2", "PG13 Official Inspection Certificate Country of Issuance PG14 Official Inspection Certificate Number PG19 Processing Establishment Number, Exporting Establishment Number, Source Establishment

Number (if applicable) PG21 Importer\Broker\Consignee Individual First and Last Name, Telephone number of the individual, Email address and\or fax number for the individual PG22 Document Identifier, Entity Role Code, Declaration Certification, Date of Signature PG30 Official Import Inspection Establishment and Estimated Date of Arrival Required PG Records for non-eCert Country PG Record Description OI Commercial Description PG01 Government Agency Code, PGA Line Number, Supplemental Product Codes (if applicable) PG02 Always P for Product PG06 Process Country, Source Country (if applicable) PG10 Species, Process Category, Product Category and Product Group (codes in Appendix PGA) PG13 Official Inspection Certificate Country of Issuance PG14 Official Inspection Certificate Number PG19 Processing Establishment Number, Exporting Establishment Number, Source Establishment Number (if applicable) PG21 Importer\Broker\Consignee Individual First and Last Name, Telephone number of the individual, Email address and\or fax number for the individual PG22 Document Identifier, Entity Role Code, Declaration Certification, Date of Signature PG25 Lot Number, Lot Production Dates (if applicable) PG26 Shipping and Immediate Container (if applicable) Package Types, Count, Shipping Mark PG29 Net Weight of Lot PG30 Official Import Inspection Establishment and Estimated Date of Arrival Foreign Inspection Certificate FSIS requires that all imported shipments of meat, poultry, egg products and Siluriformes (including catfish) be properly certified by the exporting foreign country. Some of the data elements needed to complete the ABI entry is supplied from the foreign inspection certificate, which accompanies each shipment. It is important to note that currently, FSIS receives official certification electronically from Australia, New Zealand and the Netherlands. For filers making entries from these three countries, the filer only needs to identify the inspection certificate number in PG14. 3","The PGA Message Set requirement for records identifying specific lot information will automatically populate from the data received from the foreign country\u2019s electronic certification into PHIS. Point(s) of Contact If you have questions about the content of these data samples, please contact: Mary Stanley USDA, FSIS Office of International Coordination (OIC) mary.stanley@fsis.usda.gov 202-708-9543 Phone Robert Berczik USDA, FSIS Office of Policy and Program Development (OPPD) robert.berczik@fsis.usda.gov 202-690-4163 Phone 4","CATAIR: The following are FSIS input and descriptions in the CATAIR format followed by the applicable FSIS codes from Appendix PGA and other related appendices. \u2022\u2022RISI...-, 3 & DATE FSIS 9540-1, IMPORT INSPECTION APPLICATION (Meat, Poultry  
& Egg Products) 40", "Sample 1: The FSIS form 9540-1 has been modified to capture more  
detailed information about shipments. Below are the instructions that accompany the revised  
form. Additionally, in red font, are fictitious data representing a shipment of Boneless Beef  
Trimmings from a non eCert country (Mexico) and how that information would be entered in  
ABI for the message set. This example is two foreign inspection certificates on the entry. One  
certificate has 2 lots and one certificate has 1 lot. Block: 1. Country of Origin. Enter the name of  
the country that issued the inspection certificate for the export of the product. Mexico is the  
name of the country that issued the foreign inspection certificates. This information comes  
from the entry. 2. Inspection Certificate Number. Enter the serial number, including  
dashes\slashes, from the foreign country inspection contained on the inspection certificate.  
Certificate numbers are 123456AAAA and 123456BBBB. 3. Exporting Establishment Number.  
Enter the official number of the foreign facility that the product was exported from the  
inspection certificate. Foreign establishment number 5555A is the exporting establishment  
certified on both foreign inspection certificates. 4. U.S. Port of Entry\CBP Port Code. This is the  
name of the port of entry and the associated CBP port code designation where the entry is filed  
with U.S. Customs and Border Protection (CBP). This information comes from the entry. 5. U.S.  
Port of Unlading\CBP Port Code. This is the name of the U.S. port of entry and the associated  
CBP port code for merchandise. This information comes from the entry. 6. FSIS Establishment  
Number. This is the official number assigned by FSIS to the establishment where the product  
will move for FSIS import inspection. 425. 7. Name and Address of FSIS Establishment. The name  
and address of the FSIS establishment where the product is to be moved for FSIS import  
inspection. This information comes from PHIS based on the number provided in block 6 above.  
8. Name (first\last), Business Name and Address of Customs Broker or Applicant, as applicable  
(including zip code). NOTE: the name of a responsible person is required, in addition to the  
name of the business). Business name and address come from the entry. Broker name is  
Martha Stewart. 8a. Phone Number. Martha Stewart\u2019s phone number is 3136667777 8b.  
Facsimile Number. Martha Stewart\u2019s fax number is 3136667771 8c. E-Mail Address. The  
email address is used for refused entry notifications and communication with the applicant.  
Martha Stewart\u2019s email address is JAS2@HOTMAIL.COM 9. Name (first\last), Business  
Name and Address of Consignee (including zip code): The name and address, including zip code,  
of the company or person to which the product is consigned. Business name and address come

from the entry. Consignee's name is Hilda Brand. Hilda Brand's phone number is 8566667777. Hilda Brand's email address is HILDA@HOTMAIL.COM

41","10. Enter Name (first\last), Business Name and Address of Importer of Record (IR) (including zip code). The name and address of the Importer of Record as declared to Customs when the entry is filed. Business name and address come from the entry. Importer's name is Hilda Brand. Hilda Brand's phone number is 8566667777. Hilda Brand's email address is HILDA@HOTMAIL.COM

11. Bill of Lading Number(s). Enter the applicable bill of lading numbers for this application. This information comes from the entry.

12. Lot No. The lot number of each line item of product identified on the foreign inspection certificate. Start with 1 and continue with 2, 3, etc. Certificate number 123456AAAA certifies 2 lots of boneless beef trimmings and certificate number 123456BBBB certifies 1 lot of boneless beef trimmings.

NOTE: Blocks 13 through 32 repeat for each lot on an inspection certificate. FSIS expects that each line item on the inspection certificate is one (1) lot on the form 9540-1.

13. Shipping\Identification Mark. Enter the unique number from the inspection certificate that links the product in the lot to the inspection certificate. Include slashes\dashes as appropriate. The shipping mark applied by the government of Mexico on the shipping containers (cartons; outermost package type) and certified on foreign inspection certificate number 123456AAAA for both lots 1 and lot 2 is XYXYXY123. The shipping mark applied by the government of Mexico on the shipping containers (cartons; outermost package type) and certified on foreign inspection certificate number 123456BBBB for lot 1 is ABABAB1239.

14. Custom Entry Number(s). Enter each applicable 11 digit custom entry number associated with the shipment. For locations where the custom entry number is not 11 characters long, enter enough zeros at the beginning to make an eleven digit number. This information comes from the entry.

15. Production Date(s). Enter the range of production dates from the foreign inspection certificate for each lot when applicable. These products were produced between 01012011 and 02012011. These production dates are certified for all lots on both foreign inspection certificates.

16. Net Weight of Lot. Enter the net weight of each lot in pounds from the inspection certificate. The net weight of Lot 1 certified on certificate number 123456AAAA is 23325 pounds. The net weight of Lot 2 certified on certificate number 123456AAAA is 23300 pounds. The net weight of Lot 1 certified on certificate number 123456BBBB is 23325 pounds.

17. Shipping Unit Package Type Name. Enter the type of shipping unit. Cartons as certified on both foreign inspection certificates and all lots.

18. Number of Units. Enter the number of shipping units from the inspection certificate. The number of cartons certified on certificate number 123456AAAA for Lot 1 is 1000 cartons. The number of cartons certified on certificate number 123456AAAA for Lot 2 is 1000 cartons. The number of cartons certified on certificate number 123456BBBB for Lot 1 is 2000 cartons.

19. Immediate Unit Package Type Name. Enter the type of immediate container packaging. There are no immediate containers in this shipping carton; however, we will show 100 Multi-Bags (MB) as an example in all lots.

42","20. Number per Shipping Unit. Enter the number of immediate containers contained in a shipping unit. When the amount is not standard in each shipping container, enter an average\approximate number. There are no immediate containers in this shipping carton; however, we will show 100 Multi-Bags (MB) as an example in all lots.

21. Seal Number(s). Enter the conveyance seal number(s) from the inspection certificate (egg products, red meat carcass shipments, etc.). Seal numbers are not needed for this shipment. Only certain egg products and red meat carcass shipments require seal numbers. If they were

needed, this information would be provided in a PG24 record. 22. Processing Est. No. Enter the foreign establishment number from the inspection certificate of the foreign plant that produced the product (e.g., last processed the product). Foreign establishment number 5555A is the processing\producing establishment certified on both foreign inspection certificates. 23. Source Country(s). Enter each country, other than the exporting country, from which product was sourced to produce the product in this lot. There is not a source country in this example. If there were, the source country would be identified in a repeating PG06 record as identified on the foreign inspection certificate. 24. Source Est. No. Enter each establishment, other than an establishment in the exporting country, from which product was sourced to produce the product in this lot. There is not a source establishment in this example. If there were, the source establishment would be identified in a repeating PG19 record as certified on the foreign inspection certificate. 25. HTS Code(s): Enter the 10 number Harmonized Tariff Schedule code(s) for the product(s) in the lot. This information comes from the entry. 26. Process Category. Enter the process category from the inspection certificate. The process category is Raw Product-Intact as certified on both foreign inspection certificates for all lots. 27. Product Category. Enter the product category from the inspection certificate. The product category is Raw Intact Beef as certified on both foreign inspection certificates for all lots. 28. Product Group. Enter the product group from the inspection certificate. The product group is Bnls.Mfg.Trimmings as certified on both foreign inspection certificates for all lots. 29. Species (dominant:) Enter one of the following species that the product predominantly contains: Beef, Veal, Goat, Lamb, Mutton, Pork, Horse, Equine other than horse, Chicken, Duck, Goose, Guinea, Squab, Turkey, Emu, Ostrich, or Rhea. The species is Beef as certified on both foreign inspection certificates for all lots. 29a. Additional Species (if applicable). Enter the less predominant additional species from the inspection certificate, when applicable. Refer to #29 for the applicable entries. There are no additional species for this example. FSIS is not yet capturing additional species designations in the message set. 30. Description of the Product. Enter the name or description of the product from the inspection certificate. For example, lamb legs, beef short loin, etc. Boneless Beef Trimmings. 31. Supplemental Product Code. Enter the GTIN, Intended Use Code, UPC, or other product code that is used in commerce for the product. GTIN is 100578620002680. Intended Use Code is 230.000. FSIS does not require these codes presently. FSIS will map these codes at the entry line level if provided. 43", "32. Estimated Date of Arrival. Enter the date that the product is expected to arrive at the FSIS establishment for import inspection. The importer has chosen I-425 as the official import inspection establishment for all lots associated with both certificates to present to FSIS for reinspection. The estimated date of arrival for the products associated to this customs entry at the official import inspection establishment is 08012011. 33. Printed Name of Customs Broker or Applicant. Enter actual name of person signing this application. Martha Stewart is the broker and has prepared this 9540-1 application. 34. Signature. Signature of person filing this application. Martha Stewart is the broker and has prepared this 9540-1 application. 35. Date. Enter the date the application is completed. Martha Stewart prepared\entered this application on 07262011. 44", "1 2 3 4 5 6 7 8 9 10 1 2 3 4 5 6 7 8 9 20 1 2 3 4 5 6 7 8 9 30 1 2 3 4 5 6 7 8 9 40 1 2 3 4 5 6 7 8 9 50 1 2 3 4 5 6 7 8 9 60 1 2 3 4 5 6 7 8 9 70 1 2 3 4 5 6 7 8 9 80 0 1 B O N E L E S S B E E F T R I M M I N G S P G 0 1 0 0 1 F S I F S I S R V 1 0 0 5 7 8 6 2 0 0 0 2 6 8 0 2 3 0 . 0 0 0 P G 0 2 P P G 0 6 3 9 M X P G 1 3 I S O M X P G 1 4 F S 7 1 2 3 4 5 6 A A A A P G 5 0 P G 1 0 F S 1 1 R P

The email address is used for refused entry notifications and communication with the applicant. Martha Stewart\u2019s email address is JAS2@HOTMAIL.COM 9. Name (first\last), Business Name and Address of Consignee (including zip code): The name and address, including zip code, of the company or person to which the

product is consigned. 46", "Business name and address come from the entry. Consignee\u2019s name is Hilda Brand. Hilda Brand\u2019s phone number is 8566667777. Hilda Brand\u2019s email address is HILDA@HOTMAIL.COM 10. Enter Name (first\last), Business Name and Address of Importer of Record (IR) (including zip code). The name and address of the Importer of Record as declared to Customs when the entry is filed. Business name and address come from the entry. Importer\u2019s name is Hilda Brand. Hilda Brand\u2019s phone number is 8566667777. Hilda Brand\u2019s email address is HILDA@HOTMAIL.COM 11. Bill of Lading Number(s). Enter the applicable bill of lading numbers for this application. This information comes from the entry. 12. Lot No. The lot number of each line item of product identified on the foreign inspection certificate. Start with 1 and continue with 2, 3, etc. This information comes from eCert and is not required in the message set. NOTE: Blocks 13 through 32 repeat for each lot on an inspection certificate. FSIS expects that each line item on the inspection certificate is one (1) lot on the form 9540-1. 13. Shipping\Identification Mark. Enter the unique number from the inspection certificate that links the product in the lot to the inspection certificate. Include slashes\dashes as appropriate. This information comes from eCert and is not required in the message set. 14. Custom Entry Number(s). Enter each applicable 11 digit custom entry number associated with the shipment. For locations where the custom entry number is not 11 characters long, enter enough zeros at the beginning to make an eleven digit number. This information comes from the entry. 15. Production Date(s). Enter the range of production dates from the foreign inspection certificate for each lot when applicable. This information comes from eCert and is not required in the message set. 16. Net Weight of Lot. Enter the net weight of each lot in pounds from the inspection certificate. This information comes from eCert and is not required in the message set. 17. Shipping Unit Package Type Name. Enter the type of shipping unit. This information comes from eCert and is not required in the message set. 18. Number of Units. Enter the number of shipping units from the inspection certificate. This information comes from eCert and is not required in the message set. 19.Immediate Unit Package Type Name. Enter the type of immediate container packaging. This information comes from eCert and is not required in the message set. 20. Number per Shipping Unit. Enter the number of immediate containers contained in a shipping unit. When the amount is not standard in each shipping container, enter an average\approximate number This information comes from eCert and is not required in the message set. 21. Seal Number(s). Enter the conveyance seal number(s) from the inspection certificate (egg products, red meat carcass shipments, etc.). Seal numbers are not needed for this shipment. Only certain egg products and red meat carcass shipments require seal numbers. If they were needed, this information would be provided in a PG24 record. 47", "22. Processing Est. No. Enter the foreign establishment number from the inspection certificate of the foreign plant that produced the product (e.g., last processed the product). This information comes from eCert and is not required in the message set. 23. Source Country(s). Enter each country, other than the exporting country, from which product was sourced to produce the product in this lot. This information comes from eCert and is not required in the message set. 24. Source Est. No. Enter each establishment, other than an establishment in the exporting country, from which product was sourced to produce the product in this lot. This information comes from eCert and is not required in the message set. 25. HTS Code(s): Enter the 10 number Harmonized Tariff Schedule code(s) for the product(s) in the lot. This information comes from the entry. 26.Process Category. Enter the process category

from the inspection certificate. This information comes from eCert and is not required in the message set. 27. Product Category. Enter the product category from the inspection certificate. This information comes from eCert and is not required in the message set. 28. Product Group. Enter the product group from the inspection certificate. This information comes from eCert and is not required in the message set. 29. Species (dominant:) Enter one of the following species that the product predominantly contains: Beef, Veal, Goat, Lamb, Mutton, Pork, Horse, Equine other than horse, Chicken, Duck, Goose, Guinea, Squab, Turkey, Emu, Ostrich, or Rhea. This information comes from eCert and is not required in the message set. 29a. Additional Species (if applicable). Enter the less predominant additional species from the inspection certificate, when applicable. Refer to #29 for the applicable entries. This information comes from eCert and is not required in the message set. 30. Description of the Product. Enter the name or description of the product from the inspection certificate. For example, lamb legs, beef short loin, etc.

Boneless Beef Trimmings. 31. Supplemental Product Code. Enter the GTIN, Intended Use Code, UPC, or other product code that is used in commerce for the product. This information is optional, and was not provided in this example. 32. Estimated Date of Arrival. Enter the date that the product is expected to arrive at the FSIS establishment for import inspection. The importer has chosen I-425 as the official import inspection establishment for all lots associated with these three certificates to present to FSIS for reinspection. The estimated date of arrival for the products associated to this customs entry at the official import inspection establishment is 08012011. 33. Printed Name of Customs Broker or Applicant. Enter actual name of person signing this application. Martha Stewart is the broker and has prepared this 9540-1 application. 34. Signature. Signature of person filing this application. Martha Stewart is the broker and has prepared this 9540-1 application. 48", "35. Date. Enter the date the application is completed.

USDA-FSIS", "\( \\ \"----~ What is the purpose of this guideline? Many businesses are interested in slaughtering livestock or producing meat or meat food products but are not sure if they are required to operate under Federal inspection. This guideline explains each of the exemptions from inspection, when they apply, and which Food Safety and Inspection Service \(FSIS\) regulatory requirements must still be met. Who is this guideline designed for? This guideline is designed for any person or business seeking more information about the exemptions from the requirements for inspection by FSIS, or emerging business model operators that handle meat or meat food products that are exempt from inspection requirements. FSIS currently requires inspection, unless exempted, for meat or meat food products from cattle, sheep, swine and goats. This guideline will be especially useful for producers and businesses that are exempt from inspection by regulation: \u2022 small and very small slaughter or processing establishments wishing to provide custom exempt services \(see page 4\) to owners of livestock; \u2022 retail stores making sales directly to consumers at a single location or at satellite stores owned or operated by the retail store; FSIS currently requires inspection, unless exempted, for meat or meat food products from cattle, sheep, swine, and goats. \u2022 restaurants selling or serving ready-to-eat \(RTE\) meals to individual consumers; \u2022 caterers delivering or serving RTE meals to individual consumers; \u2022 restaurant central kitchens sending RTE meals to their satellite restaurant locations or vending machines; \u2022 businesses that are a combination of a retail store and a restaurant; \u2022 internet advertisers, marketers, and brokers of meat or meat food products to consumers; \u2022 firms using common couriers to transport meat or meat food products to consumers; and \u2022 farmers wishing to engage in direct purchase agreements with school food service authorities for livestock slaughtered and prepared under State or Federal inspection. This guideline reflects FSIS\u2019s policies and procedures and can be used now. However, FSIS is requesting comments on this guideline and may make changes to it based on comments. How can I comment on this guideline? FSIS seeks comments on this guideline as part of its efforts to continuously assess and improve the effectiveness of policy documents. All interested persons may submit comments regarding any aspect of this document, including but not limited to: content, readability, applicability, and accessibility. The comment period will be 60 days and the document will be updated in response to the comments. Comments may be submitted by either of the following methods: Federal eRulemaking Portal Online submission at"\]}\]}](http://www.fsis.usda.gov/wps/portal/fsis/topics/inspection/mpidirectory/50)

regulations.gov: This Web site provides the ability to type short comments directly into the comment field on this Web page or attach a file for lengthier comments. Go to http:\www.regulations.gov and follow the online instructions at that site for submitting comments. Mail, including -CD-ROMs, and hand-or courier-delivered items: Send to Docket Clerk, U.S.Department of Agriculture (USDA), FSIS, Patriots Plaza 3, 1400 Independence Avenue SW, Mailstop 3782, 8-163A, Washington, DC 20250-3700. All items submitted by mail or electronic mail must include the Agency name -FSIS, and document title: FSIS Guideline for Determining Whether a Livestock Slaughter or Processing Operation is Exempt from the Inspection Requirements of the Federal Meat Inspection Act 2017. Comments received will be made available for public inspection and posted without change, including any personal information, to http:\www.regulations.gov. What if I still have questions after I read this guideline? If the desired information cannot be found within the Guideline, FSIS recommends that users search the publicly posted Questions & Answers (Q&As) in the askFSIS database or submit questions through askFSIS. Documenting these questions helps FSIS improve and refine present and future versions of the Guideline and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter Guideline for Livestock Exemptions Question Field: Enter question with as much detail as possible. Product Field: Select General Inspection Policy from the drop-down menu. Category Field: Select Agency Issuances from the drop-down menu. Policy Arena: Select Domestic (U.S.) Only from the drop-down menu. When all fields are complete, press Continue.", "TABLE OF CONTENTS INTRODUCTION

LIMITATIONS..... 24 ATTACHMENT 2: DEFINITIONS

..... 25 THE FOLLOWING  
REGULATORY AND COMMON STANDARD DICTIONARY DEFINITIONS WILL BE USEFUL IN  
UNDERSTANDING THE EXEMPTIONS.

26", "Introduction Under the Federal Meat Inspection Act (FMIA), FSIS conducts inspection in all establishments where cattle, goats, sheep and swine are slaughtered or processed for sale as articles of commerce, unless an exemption from inspection applies. See page 23 for more about what is meant by \u201commerce.\u201d The USDA\u2019s Food Safety and Inspection Service (FSIS) is the public health agency responsible for ensuring that the nation's commercial supply of meat, poultry, and egg products is safe, wholesome, and correctly labeled and packaged. FSIS does this by verifying compliance with its regulations, found in 9 Code of Federal Regulations (CFR) 300-599. Daily inspection is provided by FSIS or by States that operate their own meat and poultry inspection (MPI) programs that are \u201cat least equal to\u201d FSIS\u2019s inspection program. The FMIA exempts some slaughter and processing activities and operations from its inspection requirement. Those exemptions are found in 21 U.S.C. 623 and 661, and FSIS issued regulations on those exemptions (9 CFR 303.1). Facilities operating under an exemption are not exempt from the adulteration and misbranding requirements of the FMIA and may be subject to State or local regulatory requirements. Note: Exemption guidance for poultry products can be found in Guidance for Determining Whether a Poultry Slaughter or Processing Operation is Exempt from Inspection Requirements of the Poultry Products Inspection Act. What requirements apply to persons, firms or corporations wishing to conduct business under the livestock inspection exemptions? Although exempt from the daily inspection requirements, these exempt facilities remain subject to the access and examination provisions of the FMIA (21 U.S.C. 642). Therefore, business records, per 9 CFR 320.1, must be maintained and access to places of business and opportunity for examinations of facilities, inventory, and records must be provided to authorized FSIS personnel. As is noted above, meat products exempt from inspection are not exempt from the adulteration or misbranding provisions of the FMIA. The adulteration and misbranding provisions of the FMIA can be found in 21 U.S.C. 601. \u2022 A meat food product is adulterated if it o was prepared, packed or held under insanitary conditions; o is for any reason unsound, unhealthful, unwholesome or unfit for human food; o consists in whole or part of any filthy, putrid, or decomposed substance; o may have been rendered injurious to health; or o bears or contains any poisonous or deleterious substance which may render it injurious to health (i.e. undeclared allergen, chemical residue). \u2022 A meat food product is economically adulterated when any valuable constituent, in whole or in part, has been omitted or removed, or in which a less valuable substance has been substituted. \u2022 A meat food product is misbranded if its label is false or misleading, or if it does not contain the required labeling features. 1", " A \_\_ \_ ( '\\"'----\_\_ ) y Who determines whether an operation qualifies for an exemption? There is no registration requirement with FSIS or approval process The person operating the from FSIS to operate under an exemption. The person operating business determines if he the business makes the initial determination and decides which, if or she is qualified for an any, exemption applies. However, FSIS Office of

Investigation, exemption. Enforcement and Audit (OIEA) Compliance Investigators periodically verify whether the firm meets the relevant exemption FSIS OIEA Compliance requirements in 9 CFR 303.1. Investigators may verify For assistance in understanding the regulations applicable to that the establishment exempt operations, please contact the FSIS Policy Development meets the exemption Staff at 1-800-233-3935 or submit your questions through requirements in 9 CFR askFSIS. 303.1. What are the exemptions from USDA FSIS inspection? The FMIA, in 21 U.S.C. 623(a), exempts from routine Federal inspection: \u2022 Livestock slaughtered for personal use \u2022 Livestock custom slaughtered or prepared The FMIA, in 21 U.S.C. 661(c)(2), exempts from routine Federal inspection, operations of types traditionally and usually conducted at: \u2022 Retail stores \u2022 Restaurants \u2022 Restaurant central kitchen facilities \u2022 Caterers Criteria and Notes for Each Exemption A.PERSONAL USE Mandatory inspection for the slaughter and processing of privately owned livestock is not required, provided the criteria below are met (21 U.S.C. 623; 9 CFR 303.1(a)(1)): (a)The requirements of the Act and the regulations in this subchapter for inspection of the preparation of products do not apply to: (1)The slaughtering by any individual of livestock of their own raising, and the preparation by them and transportation in commerce of the carcasses, parts thereof, meat and meat food 2", "products of such livestock exclusively for use by them and the members of their household and their nonpaying guests and employees. Personal Use Criteria: 1. The resulting product from the animal slaughtered and processed under this exemption is exclusively for the private use by the: a. owner raising the livestock, b. members of their household, c. household nonpaying guests, or d. household employees. 2. The slaughter and processing of the livestock is performed by the owner of the livestock. 3. No livestock are slaughtered which are unfit for human consumption. Specified risk materials (SRMs)are inedible and prohibited for use as human food. 4. The carcass and parts are not prepared, packed, or held under insanitary conditions. Personal Use Notes: 1. All of the criteria above must be met, otherwise, the livestock is not eligible to be slaughtered and processed under this exemption, and inspection is required. 2. There is no limit on the number of livestock that an owner may slaughter and process for their personal use. 3. A person may purchase livestock from a farm or ranch and then slaughter it onsite using the farm or ranch facilities or equipment. a. If a person purchases livestock, and uses the onsite facilities without assistance from the seller, then the activity remains personal use. b. If the seller participates in the slaughter or processing activity, then the facility owner is subject to the custom exempt criteria described below. 4. Personal use products, although uninspected, may move across State lines. 5. The owners of the livestock may or may not reside at the same physical location as the animal. 6. The exempt meat food products may not be sold or donated. B. CUSTOM SLAUGHTER AND CUSTOM PROCESSING A custom exempt operator slaughters livestock belonging to someone else and processes the carcasses and parts, for the exclusive use, in the household of that owner, by the owner, members of the owner\u2019s household, non-paying-guests, and employees. The custom exempt operator may also engage in the business of buying or selling other meat and meat food products, derived from State or Federal inspected sources. A custom exempt operator may slaughter, or process custom exempt product, or do both. The owner of the livestock may opt to have his or her livestock slaughtered under the custom exemption by one 3", "\_\_\_ A \_\_\_ ( \\'----\_\_ ) y custom exempt operator, and then choose to have a second custom exempt operator do the processing. The owner of the livestock may also slaughter the animal and then

have the carcass further processed at a custom exempt processing facility. The applicable regulatory requirements are found in 9 CFR 303.1(a)(2): (a)The requirements of the Act and the regulations in this subchapter for inspection of the preparation of products do not apply to: (2)The custom slaughter by any person of cattle, sheep, swine, or goats delivered by the owner thereof for such slaughter, and the preparation by such slaughterer and transportation in commerce of the carcasses, parts thereof, meat and meat food products of such livestock, exclusively for use, in the household of such owner, by the owner and members of their household and their nonpaying guests and employees; nor to the custom preparation by any person of carcasses, parts thereof, meat or meat food products derived from the slaughter by any individual of cattle, sheep, swine, or goats of their own raising or from game animals, delivered by the owner thereof for such custom preparation, and transportation in commerce of such custom prepared articles, exclusively for use in the household of such owner, by the owner and members of their household and their nonpaying guests and employees. Custom Slaughter and Custom Processing Criteria: Custom exempt operations must result in meat and meat food products that are fit for human consumption. 1. The resulting product from the animal slaughtered and processed under this exemption is exclusively for the private use of the: a. owner of the livestock; b. members of his the owner\u2019s household; c. nonpaying guests; or d. household employees. 2. Records of the names and addresses of the owner of the livestock and products must be kept by the custom exempt operator. The recordkeeping requirements of 9 CFR 320.1 apply to custom exempt operations. 3. No livestock are slaughtered which result in food unfit for human consumption. a. For reference, in official establishments non-ambulatory disabled cattle are considered unfit for human food and must be condemned, including those that become nonambulatory after passing ante-mortem inspection (9 CFR 309.3). However, custom operators may slaughter for human food cattle that become non-ambulatory disabled after they are delivered to the custom slaughter facility if the operator of the facility does not observe any other condition that would render the animal unfit for human food (74 FR 11463, 11464). b. Field-dressed livestock (cattle, sheep, swine, goats) may be brought in for custom exempt processing. The custom exempt operator may ask the owner of any field-dressed cattle to provide a written statement that the animal was ambulatory at the time of slaughter. This statement helps to support that the beef products are safe, wholesome and unadulterated. 4", "c. The facility must handle and maintain inedible material to prevent the diversion of inedible animal products (including SRMs) into human food channels, resulting in the adulteration of human food (9 CFR 303.1(a)(2)(i), 303.1(b)(4), 381.10(a)) (4), 416.2(b)(4), and 416.3(c)). d. The regulation 9 CFR 303.1(b)(1) states that \u201cxempted custom prepared products \u2026 shall not be adulterated as defined in paragraph 1(m) of the Federal Meat Inspection Act.\u201d Therefore, custom exempt product cannot contain SRMs, including the skull, brain, trigeminal ganglia, eyes, vertebral column, spinal cord, and dorsal root ganglia of cattle 30 months of age and older. The distal ileum of the small intestine and tonsils from all cattle are SRMs, considered inedible and, therefore, are not to enter the food supply (9 CFR 310.22). See FSIS Using Dentition to Age Cattle for more information. 4. Livestock must be slaughtered and handled in compliance with the Humane Methods of Livestock Slaughter Act. 5. The facility must be operated and maintained in a manner sufficient to prevent the creation of insanitary conditions and to ensure that product is not adulterated. a. The regulatory requirements of 9 CFR 416.1 to 416.6, except for 416.2(g)(2)-

(6), apply to all custom exempt facilities. b. The additional regulatory requirements, including recordkeeping, of 9 CFR 416.12 to 416.16, apply to custom exempt operations that are conducted in an official establishment, 9 CFR 303.1(a)(2)(i). 6. The custom exempt product cannot be sold or donated as it is exclusively for the use by the owner in their household. Articles which are capable for use as human food, if not delivered to the owner, must be denatured or otherwise identified in accordance with 9 CFR 325.13, so as to be made distinguishable from human food, per 9 CFR 303.1(b)(4). 7. The carcasses and parts prepared on a custom exempt basis shall be marked as \u201cNot for Sale,\u201d or if placed in immediate containers labeled with \u201cNot for Sale,\u201d until delivered to the owner, per 9 CFR 316.16. 8. In a facility that hosts both an official establishment and an unofficial custom exempt operation, the custom exempt prepared livestock products must be kept separate and apart, per 9 CFR 303.1(a)(2)(ii), from any products that are for sale. Separation can be achieved by time or space. For example, the same cooler can be used to store both custom exempt products and inspected products. The custom exempt products are stored on separate rails or shelves and marked \u201cNot for Sale,\u201d which makes them separate and distinct from the inspected product. Custom Slaughter and Custom Processing Notes: 1. There is no registration requirement with FSIS or approval process from FSIS to operate under the custom exemption. FSIS recommends that operations that are exempt from FSIS inspection are appropriately permitted through the State and local (county, city) authorities. Check with those authorities for their applicable licensing requirements. FSIS will verify compliance with the FMIA statutory requirements, and 9 CFR regulatory requirements, annually. 2. There is no limit to the amount of livestock that an owner may slaughter and process for their personal use under the custom exemption. 5", "3. If any of the eight criteria above are not met, the custom exempt operator may be ineligible for the exemption. 4. If the custom operations are conducted in a facility that also has an official USDA inspected operation, an owner\u2019s animal may be slaughtered under USDA inspection if so desired by the owner. After the animal passes both ante-mortem and post-mortem inspections, it can be returned to the owner, unless condemned. The animal should be kept separate throughout the process in order to be returned to the owner. 5. Selling livestock to a customer does not disqualify a business from the custom exemption. A custom exempt operator may sell livestock to a person(s) prior to slaughter and then custom slaughter the animal for the new owner. The custom exempt operator would be required, upon request, to provide records, per 9 CFR 320.1(a), that fully disclose the transfer of ownership prior to slaughter or processing of the livestock. 6. The operator of a custom exempt facility may also slaughter and process their own livestock for their exclusive consumption, or members of their household, nonpaying guests or employees, under the personal use exemption. 7. Selling livestock to a customer and then allowing that owner to use onsite facilities for the slaughter of the livestock still constitutes personal use slaughter. However, once the seller assists in the slaughter or processing, then the facility becomes a custom exempt facility, subject to 9 CFR 303.1(a)(b). 8. A custom exempt operation may use a mobile slaughter and processing unit. 9. The equipment used for custom exempt slaughter and processing must be thoroughly cleaned and sanitized prior to their use for preparing any inspected products, per 9 CFR 416.12(a), to prevent direct contamination or adulteration of product(s). 10. The risk of infection from Trichinae is increased in swine that have access to rodents and wildlife, such as pasture-raised, free-range and feral swine. All forms of fresh pork, including fresh unsmoked sausage, are

customarily well cooked in the home by the consumer, and therefore the treatment of such products for the destruction of trichinae is not needed. However, in order to produce a safe, wholesome and unadulterated product, pork products that might be eaten rare or without thorough cooking because of the appearance of the finished product, may require treatment for the destruction of trichinae. 11.FSIS recommends, but does not require, that custom exempt operators keep production records of cooking and cooling of meat food products to support that they produce safe, wholesome, unadulterated products as required by the FMIA. 12.Any canned product from custom exempt livestock must be prepared in accordance with 9 CFR 318 Subpart G \u2013 Canning and Canned Products, including written processing schedules.

13.Although the items listed below are not specifically required by the HMSA, FSIS recommends the custom exempt operators: a. provide water and feed for animals in pens, 6", "b. maintain facilities in good repair to prevent injury to animals, c. drive the livestock with a minimum of excitement and discomfort, d. separate disabled animals from ambulatory animals, e. not drag disabled animals while still conscious, and f. handle animals in accordance with applicable state and local laws. 14.If an owner of the livestock wishes to transport custom exempt product from one custom exempt facility to another for further processing, they may do so. (The product must be marked \u201cNot for Sale\u201d during transportation, per 9 CFR 303.1(a)(2)(iii).)

15.Commingling of fat trimmings and meat trimmings from custom exempt animals to facilitate rendering or sausage production is allowed with each owner\u2019s written consent. All of the resulting commingled product must be clearly marked \u201cNot for Sale.\u201d See FSIS Directive 5930.1, Custom Exempt Review Process, page 9, for more information. 16.There may be more than one owner of the live animal. Sharing a live animal is acceptable provided proof of ownership of the live animal is available, upon request to the custom exempt operator, for Agency review. 17.The custom exempt operator must maintain records showing the identity of the individual owners\u2019 names prior to slaughter. In the case of more than one owner of the livestock, a list of the individual owners\u2019 names is required prior to slaughter, per 9 CFR 303.1(b)(3). 18.Carcasses and other products of custom slaughter are not eligible to be sold. Therefore, sale or purchase of the live animal using the services of a custom exempt operator would be based on live weight, price-per-head, or other quantity pertaining to the live animal. The custom exempt operator can only charge the owner a service fee for the livestock slaughtered or prepared on a custom basis, not for the meat food product itself which is derived from the custom slaughter or processing because the custom exempt operator does not own the live animal nor the resultant product. 19.The custom exempt operator can arrange the purchase of a live animal for a customer, conduct the subsequent slaughter and processing, and arrange the delivery of the \u201cNot for Sale\u201d product to the owner because the FMIA does not preclude the custom exempt operator from acting as an agent on behalf of the livestock owner. The custom operator would be required, per 9 CFR 303.1(b)(3), to provide the name and address of the owner prior to custom slaughter. C.RETAIL STORES A retail

store\u2019s sales could consist solely of orders placed by the consumer via fax, phone, or online, and shipped from the retail store. The FMIA and meat inspection regulations provide a retail store exemption for businesses that further prepare meat and meat food products for sale to consumers. Traditionally, a retail store in the 1970s, when the 9 CFR 303.1(d) regulations were implemented, consisted of a physical brick-and-mortar store. It typically included a butcher counter, where consumers could buy steaks, chops, roasts, ground meats, or meat

food products that were cooked, cured, or smoked. 7", "With the rise of catalog sales and use of the internet, today\u2019s retail venues may differ greatly from that traditional retail store. Consumers can now easily order meat food products, further prepared without FSIS inspection, under the retail store exemption, without leaving their homes. The applicable regulatory requirements are found in 9 CFR 303.1(d)(1): (d)(1) The requirements of the Act and the regulations in this subchapter for inspection of the preparation of products do not apply to operations of types traditionally and usually conducted at retail stores and restaurants, when conducted at any retail store or restaurant or similar retail-type establishment for sale in normal retail quantities or service of such articles to consumers at such establishments. (2)For purposes of paragraph (d)(1) of this section: (i)Operations of types traditionally and usually conducted at retail stores and restaurants are the following: (a)Cutting up, slicing, and trimming carcasses, halves, quarters, or wholesale cuts into retail cuts such as steaks, chops, and roasts, and freezing such cuts; (b)Grinding and freezing products made from meat; (c)Curing, cooking, smoking, rendering or refining of livestock fat, or other preparation of products, except slaughtering or the retort processing of canned products; (d)Breaking bulk shipments of products; (e)Wrapping or rewrapping products. Retail Store Criteria: 1.The retail exempt operation must have sales to consumers at the location where the meat food products are prepared under the exemption, as defined in 303.1(d)(1). a.Traditionally, this means a walk-in brick-and-mortar facility where a consumer can purchase meat from a retail display case. b.However, a retail store\u2019s sales can consist solely of orders placed by the consumer via fax, phone, or online, and shipped from the retail store, without actually having customers walk into the store. 2.In order to maintain eligibility for the retail store exemption sales can only be to consumers. There are two types of consumers: a. individual household consumers, and b. \u201cother-than-household\u201d consumers, more commonly known as hotels, restaurants and similar institutions (HRI) as determined by the Administrator in specific cases, as defined by 303.1(d)(2)(vi). 3.Neither slaughtering of livestock, nor retort processing (canning) of meat food products, can occur under the retail store exemption. Those activities require either Federal or State inspection in states that operate their own Meat and Poultry Inspection (MPI) programs (referred to as non-designated States). 8", "4. A retail store can prepare multi-ingredient meat food products for sale to other-than-household consumers, within the limitations defined in 303.1(d)(2)(i)(c). Limitations on sales to other-thanhousehold-consumers: a. If a retail exempt store prepared the meat food product by curing, cooking or smoking, rendering or refining the product, it cannot sell that product to other-than-household consumers, as defined in 303.1(d)(2)(iii)(f). b. A retail store could slice or grind meat that was cured, cooked or smoked under Federal or State inspection and sell that product to HRI accounts. c. Sales to HRI accounts cannot exceed 25% of total sales to consumers of retailprepared meat. At least 75%, in terms of dollar value, of total sales of product represents sales of product to household consumers. This is known as the 75\25 Rule. d. Sales to HRI accounts cannot exceed the calendar year dollar limitation set by the Administrator. 5. For all sales, whether to individual household consumers or to HRI, no sale is made in excess of normal retail quantities, as defined in 9 CFR 303.1(d)(2)(ii). Any quantity or product purchased by a consumer from a particular retail supplier shall be deemed to be a normal retail quantity if the quantity so purchased does not in the aggregate exceed one-half carcass. The following amounts of product will be accepted as representing one-half carcass of the species identified: One-half carcass pounds Cattle 300

Calves 37.5 Sheep 27.5 Swine 100 Goats 25 6. Only federally inspected source materials can be used in the preparation of meat food products made for sales to consumers destined for interstate commerce. In states that operate their own MPI programs, State inspected source materials can be used in the preparation of meat food products that are limited to intrastate sales. 7. Records, such as bills of sale to consumers or cash register receipts, and raw ground beef production records (if applicable) are maintained as required by 9 CFR 320.1. FSIS OIEA Investigators are to have access to examine such records to verify compliance. The misbranding provisions of the FMIA apply to meat food products that are prepared under exemption from inspection requirements. Labeling of retail exempt meat food products is enforced by FSIS investigators, and by State or local authorities. State and local authorities use the FDA Food Code as guidance for labeling. Absent the following label features, per 9 CFR 301.2, Misbranded, a retail meat food product would be misbranded, if in a package or container, unless it bears a label showing: a. the name and place of business of the manufacturer, packer, or distributor; 9", "b. an accurate statement of the quantity of the contents in terms of weight, measure, or numerical count; c. any word, statement, or other information (such as Safe Handling Instructions for meat products that are not RTE) required by or under authority of the Act; d. the common or usual name of the food, if any there be; e. the common or usual name of each ingredient if the product is fabricated from two or more ingredients; f. a handling statement such as \u201cKeep Refrigerated\u201d or \u201cKeep Frozen\u201d if product requires special handling to maintain its wholesomeness; g. nutrition labeling as specified in 9 CFR 317, Subpart B Nutrition Labeling, unless an exemption in 9 CFR 317.400 applies. Retail Store Notes: 1. FSIS recommends that operations that are exempt from inspection are appropriately permitted through the State, local (county, city), and tribal authorities. Check with those authorities for their applicable licensing requirements and applicable foodservice ordinances. 2. Typically, after permitting, the exempt operation will be subject to periodic inspections by the local authorities. Those inspections often compare the operations to the Food and Drug Administration\u2019s Food Code. 3. To ensure the product does not become unwholesome or adulterated during mail order deliveries to consumers by a retail exempt operation, or its contracted couriers, the retailer and courier must safeguard against adulteration due to temperature abuse during transportation, per FMIA 21 U.S.C. 610(d), until the consumer takes possession of such product. USDA's Identifying Food Safety Risk Factors And Educational Strategies For Consumers Purchasing Seafood And Meat Products Online can be a valuable resource to retailers for making food safety determinations regarding mail order sales. Retailers and couriers need to be aware of the FDA\u2019s Sanitary Transportation of Human and Animal Food requirements for shippers, loader and couriers. 4. The FMIA does not prohibit retail exempt store operators from using third-party businesses, such as a food hub, to: a. advertise, b. market, c. store product in commerce at an independent warehouse or food hub, prior to delivery to the consumer, d. deliver, and e. collect the money for the sale of their exempt products to consumers, but the retailer must sell the exempt meat or meat food product to the consumer in order to be exempt. The retailer cannot sell the product to the third-party business for re-sale to the consumer. 5. The FMIA does not prohibit a person, firm or corporation from preparing exempt meat food products at a central retail store location, for sale to consumers at that central location, and for unlimited distribution and subsequent sale to consumers at their satellite retail outlets, owned 10", "or operated by them, such as their

additional retail stores, kiosks, farmers market booths, or mobile food pantries.

6. FSIS recognizes that consumers may purchase raw meat or RTE meat products from a retail store via phone, fax, or online orders, and have that purchase delivered. Retailers that sell meat food products must maintain records, such as bills of sale, in accordance with 9 CFR 320, that disclose that sales were made to consumers at such location.

7. The total sales of product (303.1(d)(2)(iii)), and the annual dollar limitations for sales to otherthan-household consumers, apply to individual retail stores, rather than cumulative retail stores operating under a corporate structure.

8. The sales of pass-through (box-in, box-out, not opened) meat food products that were federally inspected do not apply to the total sales of product found in 9 CFR 303.1(d)(2)(iii)(b). Those total sales limitations apply only to products prepared under the retail exemption. There is no limit on the sales of federal or state inspected products that are not further prepared at the retail establishment.

9. A retail store can donate meat food products that they prepared, or are selling, to non-profit organizations, but that product must have been from federally or state inspected source materials.

10. Meat food product prepared under the retail exemption will NOT bear the USDA marks of inspection on the label as it was prepared without inspection.

11. Labels applied at retail are not required to have FSIS sketch approval. A retailer may carry forward any special claims found on inspected source materials. A retailer cannot apply any new claim to the product prepared under the retail store exemption. It would be false and misleading (misbranding) to apply a claim which was not found on the source material. FSIS labeling guidance can be found in A Guide to Federal Food Labeling Requirements for Meat, Poultry, and Egg Products.

D. RESTAURANTS

A restaurant is a business where meals, which may include meat food products, may be purchased. While a traditional restaurant experience may involve dining in, other restaurant business models include drive-thru windows, delivery, or carry-out options. The applicable regulatory requirements are found in 9 CFR 303.1(d)(2)(iv).

**Restaurant Criteria:**

1. RTE meat food products are prepared for sale or service in meals or as entrees directly to individual consumers at such establishments.
2. Only federally or state inspected and passed product, or product prepared at a retail store exempted by 303.1(d)(2)(iii), is handled or used in the preparation of any product.
3. No sale of product is made in excess of a normal retail quantity as defined in 303.1(d)(2)(ii). See page 10.
4. The preparation of product is limited to traditional and usual operations as defined in 303.1(d)(2)(i). See page 8.
5. Records are maintained as required by 9 CFR 320.1.

**Restaurant Notes:**

1. The restaurant serves the individual consumers directly at the physical location where the RTE meat is prepared for immediate consumption.
2. Sales made by the restaurant are not subject to the 75/25 rule, nor the calendar year dollar limitation for retail stores, as restaurants do not sell exempt product to other-than-household consumers (HRI: hotels, restaurants and similar institutions).
3. The restaurant is subject to the State and local (county, city), and tribal inspection laws. Check with those authorities for their applicable licensing requirements and applicable foodservice ordinances.
4. The restaurant is subject to the adulteration provisions of the FMIA per 9 CFR 303.1(f), therefore, the RTE meals must not be prepared, packed or held under insanitary conditions.

E. CATERERS

A caterer is a person who delivers or serves product in meals to individual consumers.

**Caterer Criteria:**

1. The definition of a restaurant includes a caterer, per 9 CFR 303.1(d)(2)(iv)(b). Product is prepared only for sale or service in meals or as entrees to individual consumers.
2. Only federally or state inspected and passed product, or such product prepared at a retail store exempted by 303.1(d)(1), is handled or used in the

preparation of any product. Meals prepared from State-inspected source material are eligible solely for sale within such State. 3. No sale of product is made in excess of a normal retail quantity as defined in 303.1(d)(2)(ii) of this section. 4. The preparation of product is limited to traditional and usual operations as defined in paragraph (d)(2)(i) of this section. 5. Records are maintained as required by the FMIA 21 U.S.C. 642 and 9 CFR 320.1, which include records that fully and correctly disclose all transactions involved in their business. Caterer Notes: 1. The caterer is a subset of the restaurant exemption. Caterers must meet the terms of the restaurant exemption, delineated above in 1-5, in order to be eligible for the exemption from Federal inspection. 2. The caterer, or their employees delivers or serves the meals, or entr\u00e9es, to the individual consumers, per 9 CFR 303.1(d)(2)(iv)(b). 12", "3. In order to maintain eligibility for the catering exemption sales can only be to individual consumers. Products not sold to consumers disqualify the caterer from the exemption and the caterer must apply for a grant of inspection. Records which fully and correctly disclose the sale of the catered product to the consumer are required per 9 CFR 320.1(b)(1). 4. The caterer is subject to in-commerce surveillance reviews by FSIS OIEA investigators, including access and examination of facilities, inventory, and records, per FMIA 21 U.S.C. 642. The caterer is also subject to State and local licensing requirements and periodic inspection by local authorities to ensure proper sanitation and food handling. 5. The caterer is subject to the adulteration provisions of the FMIA per 9 CFR 303.1(f), therefore, the catered RTE meals must not be prepared, packed or held under insanitary conditions. The caterer, or their employees, should consider storage, holding, and reheating conditions in order to ensure delivery to consumers of a safe, unadulterated meal. Inadequate storage, holding, or reheating temperatures could lead to dangerous levels of pathogens in the foods.

F. RESTAURANT CENTRAL KITCHENS

The increase in large restaurant chains and fast food operations has contributed to a trend in the centralization of meat preparation systems. By centralizing preparation of products, a restaurant business can improve its efficiency. A restaurant central kitchen (RCK) exemption is provided, in 9 CFR 303.1(d)(2)(iv))(c), for a central kitchen that prepares RTE meat products for sale to consumers at their satellite restaurants.

Restaurant Central Kitchen Criteria:

1. The product is RTE upon departure from the RCK (i.e., no further preparation such as cooking is needed, except that it may be reheated prior to serving).
2. The transportation is direct between the RCK and satellite restaurant or vending machine location with no intervening transfer or storage. Only federally inspected source materials can be used in the preparation of meat food products destined for interstate sales.
3. The product is to be served, without intervening sale, in meals or as entr\u00e9es only to customers at satellite restaurants, or through vending machines, owned or operated by the same individual, firm, or corporation owning or operating the restaurant central kitchen.
4. The facilities are maintained in a sanitary manner.
5. Records are maintained as required by 9 CFR 320.1.

Restaurant Central Kitchen Notes:

1. The RCK may or may not serve consumers at the RCK location.
2. The RCK is subject to the State and local (county, city) inspection laws. Check with those authorities for their applicable licensing requirements and applicable foodservice ordinances.
3. All RCKs are subject to periodic inspection by local governments and by FSIS to ensure proper sanitation and food handling.
4. To lessen the likelihood of product mishandling and potential adulteration, the RTE product must be sent directly to the satellite restaurant by satellite restaurant or RCK employees.

Distribution to

franchise restaurants is acceptable if the franchises are owned or operated by the same person, firm or corporation that owns or operates the RCK. 5. If refrigerated prior to delivery, good manufacturing practices should be used that ensure the RTE meals are kept at 40\u00b0F or below. 6. RCKs operated by a city, county, or State also qualify for the exemption, provided meals are served at facilities controlled by the city, county, or State. 14", "11 ) \u009d 11 i ~ 11 ) \u009d 11 i ! \u009d 11 .... , ! ~ .... \u009d 11 , ! ~ How do I determine if I am eligible for one of these exemptions? In order to determine whether your livestock slaughter or meat processing operation qualifies for an exemption from the Federal Meat Inspection Act, ask yourself the question in the bold type and then follow the appropriate Yes or No response arrow. Do you slaughter and process livestock for human food? Yes No Inspection requirements of FMIA not applicable Is the livestock you slaughter and process for your personal use? Farmers and ranchers selling into local and regional food systems have unique needs from navigating seeds, breeds, and production systems to adopting on-farm risk management and food safety activities. USDA supports and invests in local and regional food systems from coast to coast, in every state, as part of the department\u2019s commitment to revitalizing rural America. USDA strengthens local and regional food systems by coordinating relevant activities across its 17 agencies and by investing in projects that recruit and train farmers and ranchers, expand economic opportunities for small businesses, and increase access to healthy foods. Consumers across the country can find

locally produced food at their neighborhood grocery stores, restaurants, and farmers markets. Learn more about USDA's tools and programs to help farmers, ranchers, processors, and distributors produce food for local and regional markets at USDA Agricultural Marketing Service, Local and Regional Food Sector. The information below provides guidance for meat production in a variety of local market business models. Local Marketing and Direct-to-Consumer sales Consumers and businesses are increasingly interested in direct, regional, and local markets that minimize the distance that food products travel from production to consumption. Local and regional sales can be either direct-to-consumer (for example, through farmers markets or Community Supported Agriculture) or sold through so-called intermediated markets such as food hubs, which then market to consumers. Local and regional marketing can add value to a food product by maintaining farm identity in marketing, building relationships and loyalty between consumers and producers, targeting specialty or niche markets, and making production practices and ingredients more transparent. USDA does not officially define local or regional, so the exact meaning of the terms currently used in commerce may vary depending on the goals of the producer, buyer, or organization promoting local market connections. Local and Regional Marketing and Direct-to-Consumer Sales Notes: When selling locally-produced meat direct to consumers, keep in mind that only livestock slaughtered and processed under Federal inspection can be sold across state lines (interstate). Meat from livestock slaughtered and processed under State inspection is limited to commerce within the state (intrastate). If slaughtered and processed under Federal or State inspection, local meat can be sold direct to household consumers through farmers markets and to other-than-household consumers, within limitations described above in Retail Store Criteria, page 8. If local meat products are slaughtered under Federal or State inspection and are then further prepared (i.e. operations of types traditionally and usually conducted at retail stores: see 9 CFR 303.1(d)(2)), by a local seller, the local seller must be inspected unless it is eligible for the retail store exemption (see page 8). Retail stores that are exempt from Federal inspection, however, are subject to State and local (city, county) inspection laws. For all local and regional food markets, FSIS recommends: Farmers and businesses follow voluntary food safety practices to ensure a standard of care for their products and to reassure buyers regarding the steps taken to reduce risks of foodborne illness. Farmers and businesses reduce the risk of dangerous bacteria or toxins in farm products by following established food safety guidance, including the following: o develop a food safety plan, o train employees in proper food safety management, and o document all farm practices. Emerging Local and Regional Food Business Models What are some of the emerging business models? Business models, including those described below, are emerging as a result of the growing demand for locally and regionally produced food. Farmers Markets A farmers market is an open retail market that features fruits, vegetables, meats, eggs, and other commodities sold directly from producer to consumers. Typically, each producer brings their own booth, tables, or stands, and consumers purchases products directly from the farmers. This facilitates personal connections and creates mutual benefits for local producers, consumers, and communities. USDA's Agricultural Marketing Service (AMS) defines a farmers market as markets that feature two or more farm vendors selling agricultural products directly to customers at a common, recurrent physical location. Farmers Markets Notes: 1. Livestock meat food products, like beef jerky, must have been prepared from federally or state inspected

source material. If the meat food product sold at the farmers market is moved in interstate commerce, then the source material used to prepare the meat food product must be federally inspected. 2. FSIS OIEA Compliance Investigators may do reviews of booths selling meat food products, in accordance with FSIS Directive 8010.1. 3. Typically, the booths are appropriately permitted by the local (county, city) authorities and regulated by the local food establishment requirements. 4. Onsite preparation of meat food products at farmers markets may be regulated by State and local laws, or the farmers market's own food safety rules. 5. A farmers market booth can be an additional retail outlet of a retail store, where product is sold to individual household consumers in normal retail quantities. 6. Perishable meat should be properly refrigerated at the market and be kept in closed coolers with adequate amounts of ice to maintain cool temperatures. See FSIS Refrigeration and Food Safety guidance for more information. 18", "7. Raw meat should be handled appropriately so that the juices, which may contain harmful bacteria, do not come in contact with other foods or food contact surfaces. 8. RTE meat products should not be handled with bare hands, or by ill food handlers. 9. Packaged meat food products must not be misbranded. Be sure the label contains: a. The common name of the meat food product. b. A list of ingredients if there are more than two ingredients, in descending order of predominance. c. Net quantity specifications (weight, volume). d. Name and address of the business that prepared the meat food product. e. No marks of USDA inspection, or state inspection, unless the meat food product was actually prepared under inspection and is still intact as prepared and packaged by the federally or state inspected establishment. h. Safe-handling instructions if the product is raw. i. A handling statement such as \u201cKeep Refrigerated\u201d or \u201cKeep Frozen\u201d if product requires special handling to maintain its wholesomeness. f. nutrition labeling as specified in 9 CFR 317, Subpart B Nutrition Labeling, unless an exemption in 9 CFR 317.400 applies. 10. Check with your State and local (county, city) authorities about using a private kitchen in a person's living quarters for preparing meat food products sold at farmers markets. Food Hubs A food hub is a business or organization that actively manages the aggregation, distribution, and marketing of source-identified food products primarily from local and regional producers to strengthen their ability to satisfy wholesale, retail, and institutional demand. They provide a bridge from food producer to consumer by creating a business that actively works to distribute and market locally and regionally sourced food products. By providing small producers with access to larger volume markets, food hubs can support producers while also helping buyers meet the growing consumer demand for local food. Food Hub Notes: 1. Food hubs can advertise, broker, and deliver retail exempt meat food products for the exempt operator, but the exempt operator must maintain ownership of the product and make the sale to the consumer in order to be exempt from inspection. The records maintained by the retailer must fully and correctly disclose the sale of the meat food product from the retailer to the consumer. 2. The food hub may market: o federally inspected product in intact packages from the federally inspected establishment, which is eligible to move in interstate commerce, o State inspected product in intact packages from the state inspected establishment, which is eligible to move only in intrastate commerce, 19", "o Retail exempt product prepared under the retail store exemption, which is owned by the retailer. The retail exempt operator must own and sell the retail exempt product to the consumer. Bills of sale, which fully and correctly disclose the sale of the exempt product by the retail exempt operator to the consumer, must be maintained.

\uf0a7 Retail exempt product prepared from Federally inspected source materials product may move in interstate commerce. \uf0a7 Retail exempt product prepared from state inspected source material, in those States that operate their own meat and poultry inspection (MPI) programs, are restricted to intrastate commerce only.

3. The food hub must maintain records, per 9 CFR 320.1, such as invoices, bills of lading, and receiving and shipping papers for any meat food product that is shipped, received, transported or otherwise handled. All such records are subject to examination by USDA Investigators.

4. The food hub must register with the USDA as a meat food handler (transporting in commerce) with FSIS Form 5020-1, Registration of Meat and Poultry Handlers.

5. Generally speaking, food hubs do not prepare meat food products. If a food hub prepares (see: 9 CFR 301.2 definition for prepared) meat food products, then it must do so under inspection, or under one of the exemptions described above.

Farm to School Within local and regional markets, schools offer a compelling opportunity to connect young people to local food and agriculture. Farm to school initiatives include efforts to bring locally or regionally produced foods into school cafeterias; hands-on learning activities such as school gardening, farm visits, and culinary classes; and the integration of food-related education into the regular, standardsbased classroom curriculum. Locally sourced food (which creates economic opportunities for local food producers) can span the school meal tray and include everything from fresh fruit and vegetable servings to the wheat in the pizza crust, beans in the chili, rice in the stir fry, turkey in the sandwiches, and cheese in the quesadillas.

Farm to school includes all types of producers and food businesses, including farmers, ranchers, and fishermen, as well as food processors, manufacturers, and distributors.

Farm to School Notes: FSIS requirements:

1. All meat products that are to be served in a school lunch program must be, at a minimum, slaughtered in a federally or state inspected facility.
2. Meat and meat food products may be further prepared under the exemptions described above only if sold to consumers. Consumers are defined in 9 CFR 303.1(d)(2)(vi). Schools are an other-than-household consumer as an institution similar to a hotel.
3. Animals that are slaughtered or processed under a custom exemption, or under the personal use exemption, are not allowed to be used in school lunch programs. That meat is to be used exclusively by the owner of the animal in their household.

Additionally, FSIS recommends that farmers and schools involved in farm to school or school garden programs follow accepted food safety practices and have a food safety plan in place to reduce the risk of foodborne illnesses. More guidance for schools interested in procuring local meat, poultry, 20", "game, and eggs for child nutrition programs is available here: <http://www.fns.usda.gov/procuringlocal-meat-poultry-game-and-eggs-child-nutrition-programs>.

Online Markets Online markets are much like food hubs in that they bridge the gap from food producer to consumer, but instead of having a physical market, all transactions are performed through the Internet. This gives consumers the convenience of placing orders online with established producers who sell fresh, local goods. Often, an online market will feature products from many different producers. In some cases, the online marketplace does not take ownership of the product, but simply provides services such as: \u2022 advertising\marketing, \u2022 hosting the platform on which the products are marketed to consumers, \u2022 transporting or distributing the product, \u2022 collecting the money for the sale of the products to consumers. The FMIA does not prohibit a person, firm or corporation from performing these online marketing services for a retail exempt operator. The FSIS policy is, therefore, that an online market (or a food hub) is not precluded from acting as an agent of the

retailer. The online market and the retail exempt operator would be expected to provide documentary proof of their agency relationship. Both the retail exempt operator and the online market would be required to keep records and to fully and correctly disclose all transactions involved in their business, per 9 CFR 320.1, including bills of sale from the retail exempt operator to the consumer for the meat food product produced under exemption and sold to the consumer. Online Market Notes: 1. Retail exempt meat food products offered on an online market must be owned by the retailer, not by the online market. 2. In order to be exempt, the retail store must sell the product to the consumer. 3. The online market must register with the USDA as a meat food handler (broker or transporter) with FSIS Form 5020-1. Home Delivered Meals Home delivered meals programs deliver prepared meals or meal kits for in-home preparation to consumers. Many new companies are following this idea and creating businesses that design and deliver fresh, healthy meals to consumer's doorsteps. These companies may market their products as a way to lose weight or conveniently follow a healthier lifestyle by including fresh, locally sourced products in their meals. Home Delivered Meals Notes: 1. Since they sell either RTE or uncooked meals to consumers, they are a retail store. As such, see the retail store exemption criteria and notes above starting on page 8. 2. The Home Delivered Meals business is subject to the state and local (county, city) inspection laws. Check with those authorities for their applicable licensing requirements and applicable food establishment ordinances. 21", "How does FSIS verify that facilities exempt from inspection meet applicable requirements? States with \u201cequal to\u201d meat inspection programs, or FSIS\u2019s Office of Field Operations (OFO) District Office, or FSIS OIEA designated personnel typically review custom exempt operations. At retail stores, warehouses, and other in-commerce establishments, OIEA Compliance Investigators conduct onsite reviews to verify compliance with the FMIA and FSIS\u2019s regulations. The investigators, or any duly authorized representative of the Secretary, also have access to your place of business at all reasonable times and have the opportunity to examine your facility, inventory, and records. Although your business may not be subject to the daily inspection requirements by the FSIS, FSIS still has statutory authority, per FMIA 21 U.S.C. 672, to detain (to officially prevent the meat food product from leaving a place) your exempt product should it be found to be adulterated or misbranded. At facilities that house both an official establishment and a retail exempt establishment, the OFO inspectors will verify that sanitary conditions are maintained for the federally inspected establishment. The State and local government, or the FSIS OIEA Compliance Investigators, will verify the exempt operations meets sanitation and recordkeeping requirements. If your facility houses both an official establishment and an exempt establishment, be aware you will have to maintain separation between the official (inspected) and unofficial (exempt) establishments per 9 CFR 305.2(a), and, as always, maintain sanitary conditions for both operations. If OFO inspectors have concerns about the exempt facility, they will not inspect that operation, but they will turn over their concerns to the OIEA Compliance Investigators. What other government entity will have an active role in my exempt business While FSIS maintains jurisdiction over amenable meat food products that are \u201cin-commerce,\u201d the Department of Health and Human Service Food and Drug Administration (FDA) regulates all food service establishments and food processing establishments that are not under FSIS jurisdiction. FDA regulates food products not under FSIS inspection such as rabbit, buffalo, venison (if none of these are under FSIS voluntary

inspection), fish (except of the order Siluriformes), seafood, and food ingredients introduced into or offered for sale in interstate commerce. The FDA's regulations are in Title 21 of the CFR. The FDA also provides a uniform Food Code that many States and local authorities have adopted to safeguard public health and ensure that food is unadulterated and honestly presented when offered to consumers. To carry out certain provisions of the Bioterrorism Act, FDA established regulations requiring that food facilities register with FDA. Be aware of any impact the FDA's rules under the Food Safety and Modernization Act has on your exempt business or related business. Generally, the FDA does not inspect retail food service establishments. The retail food establishments are regulated by State and local (county, city) governments, although FDA retains jurisdiction over these retail operations. More than 3,000 State, local, and tribal agencies have primary responsibility to regulate the retail food and foodservice industries in the United States. They are responsible for the inspection and oversight of over 1 million food establishments (2013 restaurants 22," and grocery stores, as well as vending machines, cafeterias, and other outlets in health-care facilities, schools, and correctional facilities. Most custom exempt operations are under State or local regulation as well. You can use the Directory of State and Local Officials to obtain more information from State and local regulatory officials involved with food and food defense. The slaughter of other animals for food is regulated by the Food and Drug Administration (FDA). However, FSIS provides voluntary inspection on a fee-for-service basis for certain species, including bison, buffalo, deer, rabbits, migratory water fowl, and game birds (see 9 CFR 352, 354, and 362). Some States do consider these species to be inspected under State inspection. What is meant by "commerce" with regards to exempted meat food products? For the purpose of this regulation, the Agency defines "commerce" as product that is out of the producing establishment's direct control and is in distribution (e.g., in another Federal establishment, in a warehouse, distribution center, retail facility, restaurant, or other institution). Domestic product is considered in commerce if it has been shipped from a firm without Agency or firm controls or restrictions and is free to be moved to any consignee or to consumers. The term "of commerce" (9 CFR 302.1(a)(1), or "for commerce" (9 CFR 320.1(a)(1)) means an article of human food being offered for commercial gain. Custom exempt meat food products may be transported "from the location where the animal was slaughtered or processed to the owner of the animal from which the meat was derived. The custom exempt meat food products must not bear the mark of inspection, since they were not prepared under USDA inspection, and must be marked Not for Sale. Meat food products prepared under the retail store or restaurant exemptions from federally inspected meat sources may move in interstate commerce. Therefore, products sold to consumers in other states (including products shipped to consumers in other states) must be derived from USDA inspected source materials. Retail-exempt meat food products prepared from state inspected product can be sold solely within such State. 23," "r-----, '-----' Additional Guidance (2022 Sanitation Guidance for Beef Grinders (2022 Best Practices Guidance for Controlling Listeria monocytogenes (Lm) in Retail Delicatessens (2022 FSIS Compliance Guideline for Meat and Poultry Jerky Produced by Small and Very Small Establishments (2022 Guidance for Determining Whether a Poultry Slaughter or Processing Operation is Exempt from Inspection Requirements of the Poultry Products Inspection Act (2022 Sanitation Performance Standards

Regulatory definitions (found in 9 CFR 300-599): Exotic animal. Any reindeer, elk, deer, antelope, water buffalo, yak or bison Firm. Any partnership, association, or other unincorporated business organization. Further processing. Smoking, cooking, canning, curing, refining, or rendering in an official establishment of product previously prepared in official establishments. \u201cInspected and passed\u201d or \u201cU.S. Inspected and Passed\u201d or \u201cU.S. Inspected and Passed by Department of Agriculture\u201d (or any authorized abbreviation thereof). This term means that the product so identified has been inspected and passed under the regulations in this subchapter, and at the time it was inspected, passed, and identified, it was found to be not adulterated. Label. A display of written, printed, or graphic matter upon the immediate container (not including package liners) of any article. Livestock. Cattle, sheep, swine, or goat. Meat. (1) The part of the

muscle of any cattle, sheep, swine, or goats which is skeletal or which is found in the tongue, diaphragm, heart, or esophagus, with or without the accompanying and overlying fat, and the portions of bone (in bone-in product such as T-bone or porterhouse steak), skin, sinew, nerve, and blood vessels which normally accompany the muscle tissue and that are not separated from it in the process of dressing. As applied to products of equines, this term has a comparable meaning. (i) Meat does not include the muscle found in the lips, snout, or ears. (ii) Meat may not include significant portions of bone, including hard bone and related components, such as bone marrow, or any amount of brain, trigeminal ganglia, spinal cord, or dorsal root ganglia (DRG). Misbranded. This term applies to any carcass, part thereof, meat or meat food product under one or more of the following circumstances: (1) If its labeling is false or misleading in any particular; (2) If it is offered for sale under the name of another food; (3) If it is an imitation of another food, unless its label bears, in type of uniform size and prominence, the word \u201cimitation\u201d and immediately thereafter, the name of the food imitated; (4) If its container is so made, formed, or filled as to be misleading; (5) If in a package or other container unless it bears a label showing: (i) The name and place of business of the manufacturer, packer, or distributor; and (ii) An accurate statement of the quantity of the contents in terms of weight, measure, or numerical count; except as otherwise provided in part 317 of this subchapter with respect to the quantity of contents; (6) If any word, statement, or other information required by or under authority of the Act to appear on the label or other labeling is not prominently placed thereon with such conspicuously (as compared with other words, statements, designs, or devices, in the labeling) and in such terms as to render it likely to be read and understood by the ordinary individual under customary conditions of purchase and use; (7) If it purports to be or is represented as a food for which a definition and standard of identity or composition has been prescribed by the regulations in part 319 of this subchapter unless: (i) It conforms to such definition and standard, and (ii) Its label bears the name of the food specified in the definition and standard and, insofar as may be required by such regulations, the common names of optional ingredients (other than spices, flavoring, and coloring) present in such food; (8) If it purports to be or is represented as a food for which a standard or standards of fill of container have been prescribed by the regulations in part 319 of this subchapter, and it falls below the standard of fill of container applicable thereto, unless its label bears, in such manner and form as such regulations specify, a statement that it falls below such standard; (9) If it is not subject to the provisions of paragraph (v)(7)(ii) of this section unless its label bears: (i) The common or usual name of the food, if any there be, and (ii) In case it is fabricated from two or more ingredients, the common or usual name of each such ingredient, except as otherwise provided in part 317 of this subchapter; (10) If it purports to be or is represented for special dietary uses, unless its label bears such information concerning its vitamin, mineral, and other dietary properties as is required by the regulations in part 317 of this subchapter. (11) If it bears or contains any artificial flavoring, artificial coloring, or chemical preservative, unless it bears a label stating that fact; except as otherwise provided by the regulations in part 317 of this subchapter; or (12) If it fails to bear, directly thereon or on its containers, when required by the regulations in part 316 or 317 of this subchapter, the inspection legend and, unrestricted by any of the foregoing, such other information as the Administrator may require in such regulations to assure that it will not have false or misleading labeling and that the public will be informed of the manner of handling required to maintain

the article in a wholesome condition. Official establishment. Any slaughtering, cutting, boning, meat canning, curing, smoking, salting, packing, rendering, or similar establishment at which inspection is maintained under the regulations in this subchapter. Official inspection legend. Any symbol prescribed by the regulations in this subchapter showing that an article was inspected and passed in accordance with the Act. Official mark. The official inspection legend or any other symbol prescribed by the regulations in this subchapter to identify the status of any article or animal under the Act. Person. Any individual, firm, or corporation. Prepared. Slaughtered, canned, salted, rendered, boned, cut up, or otherwise manufactured or processed. 27", "Ready-to-eat (RTE) product. A meat or poultry product that is in a form that is edible without additional preparation to achieve food safety and may receive additional preparation for palatability or aesthetic, epicurean, gastronomic, or culinary purposes. RTE product is not required to bear a safehandling instruction (as required for non-RTE products by 9 CFR 317.2(l) and 381.125(b)) or other labeling that directs that the product must be cooked or otherwise treated for safety, and can include frozen meat and poultry products. Restaurant. A food establishment where product is prepared for sale or service as RTE meals to individual consumers at such establishments. Retort. A pressure vessel designed for thermal processing of product packed in hermetically sealed containers. Voluntary inspection service. An inspection and certification service for wholesomeness relating to the slaughter and processing of exotic animals and the processing of exotic animal products. Regulatory definitions (found in FDA Food Code 2017) CFR. Code of Federal Regulations Commminated. Reduced in size by methods including chopping, flaking, grinding, or mincing. Consumer. A person who is a member of the public, takes possession of FOOD, is not functioning in the capacity of an operator of a FOOD ESTABLISHMENT or FOOD PROCESSING PLANT, and does not offer the FOOD for resale. Employee. The PERMIT HOLDER, PERSON IN CHARGE, FOOD EMPLOYEE, PERSON having supervisory or management duties, PERSON on the payroll, family member, volunteer, PERSON performing work under contractual agreement, or other PERSON working in a FOOD ESTABLISHMENT. FDA. The U.S. Food and Drug Administration. Food employee. An individual working with unPACKAGED FOOD, FOOD EQUIPMENT or UTENSILS, or FOOD-CONTACT SURFACES. Food Establishment. (1) \"Food establishment\" means an operation that: (a)stores, prepares, packages, serves, vends food directly to the consumer, or otherwise provides FOOD for human consumption such as a restaurant; satellite or catered feeding location; catering operation if the operation provides FOOD directly to a CONSUMER or to a conveyance used to transport people; market; vending location; conveyance used to transport people; institution; or FOOD bank; and (b)relinquishes possession of FOOD to a CONSUMER directly, or indirectly through a delivery service such as home delivery of grocery orders or restaurant takeout orders, or delivery service that is provided by common carriers. (2) \"Food establishment\" includes: (a) An element of the operation such as a transportation vehicle or a central preparation facility that supplies a vending location or satellite feeding location unless the vending or feeding location is permitted by the REGULATORY AUTHORITY; and 28", "(b)An operation that is conducted in a mobile, stationary, temporary, or permanent facility or location; where consumption is on or off the PREMISES; and regardless of whether there is a charge for the FOOD. (3) \"Food establishment\" does not include: (a) An establishment that offers only prePACKAGED FOODS that are not TIME\TEMPERATURE CONTROL FOR SAFETY FOODS; (b)A produce stand that only offers whole, uncut fresh fruits and vegetables; (c)A FOOD

PROCESSING PLANT; including those that are located on the PREMISES of a FOOD ESTABLISHMENT (d)A kitchen in a private home if only FOOD that is not TIME\TEMPERATURE CONTROL FOR SAFETY FOOD, is prepared for sale or service at a function such as a religious or charitable organization\u2019s bake sale if allowed by LAW and if the CONSUMER is informed by a clearly visible placard at the sales or service location that the FOOD is prepared in a kitchen that is not subject to regulation and inspection by the REGULATORY AUTHORITY; (e)An area where FOOD that is prepared as specified in Subparagraph (3)(d) of this definition is sold or offered for human consumption; (f) A kitchen in a private home, such as a small family day-care provider; or a bed-andbreakfast operation that prepares and offers FOOD to guests if the home is owner occupied, the number of available guest bedrooms does not exceed 6, breakfast is the only meal offered, the number of guests served does not exceed 18, and the CONSUMER is informed by statements contained in published advertisements, mailed brochures, and placards posted at the registration area that the FOOD is prepared in a kitchen that is not regulated and inspected by the REGULATORY AUTHORITY; or (g)A private home that receives catered or home-delivered FOOD. Game Animal. (1)\\"Game animal\\" means an animal, the products of which are FOOD, that is not classified as livestock, sheep, swine, goat, horse, mule, or other equine in 9 CFR 301.2 Definitions, or as Poultry. (2)\\"Game animal\\" includes mammals such as reindeer, elk, deer, antelope, water buffalo, bison, rabbit, squirrel, opossum, raccoon, nutria, or muskrat, and nonaquatic reptiles such as land snakes. (3)\\"Game animal\\" does not include RATITES. HACCP plan. Means a written document that delineates the formal procedures for following the HAZARD Analysis and CRITICAL CONTROL POINT principles developed by The National Advisory Committee on Microbiological Criteria for Foods. Law. Means applicable local, state, and federal statutes, regulations, and ordinances. Permit. Means the document issued by the REGULATORY AUTHORITY that authorizes a PERSON to operate a FOOD ESTABLISHMENT. 29","Premises. Means: (1)The PHYSICAL FACILITY, its contents, and the contiguous land or property under the control of the PERMIT HOLDER; or (2)The PHYSICAL FACILITY, its contents, and the land or property not described in Subparagraph (1) of this definition if its facilities and contents are under the control of the PERMIT HOLDER and may impact FOOD ESTABLISHMENT personnel, facilities, or operations, and a FOOD ESTABLISHMENT is only one component of a larger operation such as a health care facility, hotel, motel, school, recreational camp, or prison. Regulatory authority. Means the local, state, or federal enforcement body or authorized representative having jurisdiction over the FOOD ESTABLISHMENT. Vending machine. Means a self-service device that, upon insertion of a coin, paper currency, token, card, or key, or by optional manual operation, dispenses unit servings of FOOD in bulk or in packages without the necessity of replenishing the device between each vending operation. Terms with no regulatory definition (If neither 9 Code of Federal Regulations (CFR), nor 21 CFR, nor the Statute defines a term, then the usage found in any Standard American English dictionary applies.) Broker: a person who helps other people to reach agreements, to make deals, or to buy and sell property (such as stocks or houses) 1.1.1.1 Community Supported Agriculture (CSA): a system in which a farm operation is supported by shareholders within the community who share both the benefits and risks of food production. Courier: a person who transports a meat food product to the consumer Mail order: a meat food product that is sent by mail to the consumer who bought it Operate: control the functioning of (a machine, process, or system). 30","<http://askfsis.custhelp.com/> FSIS\USDA

FSIS is issuing this guideline to help FSIS-regulated establishments, retail food outlets, and foodservice entities mitigate the public health risks from chicken liver. Who is this guideline designed for? This document is designed for FSIS-regulated establishments, and retail food outlets, and foodservice entities, including hotels, restaurants, and institutions, that produce raw (not-ready-to-eat) chicken liver, or products made from chicken liver, for human consumption. It provides guidance to assist establishments in reducing the public health risk associated with chicken liver. Additionally, retail food outlets and foodservice entities may find this guidance useful when considering suppliers for chicken liver for use in p\u00e2t\u00e9 or similar dishes. These entities may also find it useful when considering preparation practices, as this guidance explains the need to fully cook chicken liver due to the potential for the external and internal presence of pathogens. The document discusses recommendations by FSIS, based on currently available scientific evidence and practical considerations. The recommendations are not requirements that must be met. Establishments may choose to adopt different procedures than those outlined in the guideline, but they would need to support why those procedures are effective. This guideline represents FSIS\u2019s current thinking on this topic, and FSIS encourages official establishments and others to use it. Why was this guidance developed? Several reports of outbreaks of Campylobacter and Salmonella illnesses associated with chicken liver consumption have been published (USDA-FSIS, 2011; CDC, 2013; CDC, 2015; CDC, 2017). According to a recent presentation summarizing a review of these outbreaks, 22 chicken liver\u2013associated campylobacteriosis and salmonellosis outbreaks were reported to public health authorities in the United States during 2000\u20132015, comprising 331 total reported illnesses (Lanier et al., 2017). Over half of these outbreaks occurred during 2014\u20132015 and represented 21\u201334% of chicken-related outbreaks (CDC, 2016; CDC, 2017). Commonly reported outbreak features included: 1) Consumption of a blended chicken liver dish (e.g., p\u00e2t\u00e9); 2) Inadequate cooking of the chicken liver dish; and/or 3) Consumption of the chicken liver dish outside the home (e.g., in a restaurant). Another factor that likely contributed to these outbreaks is the potential for pathogens to 1", "FSIS Guideline: Chicken Liver July 2018 be present both on the surface and internally. These findings led to the recommendations in this guideline to promote a reduction in pathogens in raw chicken liver products and to promote thorough cooking of these products. Can chicken liver be contaminated with pathogens? Yes, similar to other raw poultry products, chicken liver can be contaminated with pathogens such as Campylobacter and Salmonella. Surface contamination can result from insanitary dressing procedures, as well as from the processing environment. In addition to surface contamination, chicken liver can contain pathogens internally, even when chickens are dressed in a sanitary manner. Studies have demonstrated the presence of

Campylobacter in the internal tissue of between 10% and 90% of tested chicken livers after the external surface was sanitized (Boukraa et al., 1991; Barot et al., 1983; Baumgartner et al., 1995; Firleyanti et al., 2016; Whyte et al., 2006). Additionally, researchers have detected Campylobacter and Salmonella in the liver of chickens previously free of these pathogens after experimental oral inoculation (Chaloner et al., 2014; Knudsen et al., 2006; Sanyal et al., 1984; Borsoi et al., 2009; Gast et al., 2013; He et al., 2010). Pathogens are thought to spread from the intestine to the internal liver tissue via the biliary, lymphatic, or vascular systems, although the exact route is unclear. Why is the presence of pathogens in the internal tissue of chicken liver a problem? Some recipes for chicken liver dishes, such as p\u00e2t\u00e9, instruct the preparer to only partially cook the liver (e.g., by searing). Partial cooking may kill pathogens on the external surface, but will likely not kill all pathogens in the internal tissue. Any internal pathogens that survive in products made from inadequately cooked chicken liver could make consumers sick. Inadequate cooking was a contributing factor in many of the reported illness outbreaks associated with chicken liver. How should retail food outlets, foodservice entities, and consumers prepare chicken liver? The main message for food preparers at retail food outlets and foodservice entities and at home is that chicken liver dishes, like all poultry products, should be consumed only after being cooked throughout to a safe minimum internal temperature of 165 \u00b0F (73.9 \u00b0C) as measured with a food thermometer (Food Code, 3-401.11). For food safety reasons, this should be done regardless of preferences. In addition, with respect to storage, FSIS recommends using chicken liver within one to two days if stored in a refrigerator set at 40 \u00b0F or below, or within three to four months if 2 frozen at 0 \u00b0F or below. Further information on the safe handling of chicken liver and "FSIS Guideline: Chicken Liver July 2018 other giblets is available on Foodsafety.gov. What can establishments do to lower the risks to consumers associated with chicken liver? The Hazard Analysis and Critical Control Points (HACCP) system of each establishment that produces chicken liver for human consumption is required to adequately address food safety hazards reasonably likely to occur, including external and internal pathogens. As part of the HACCP requirements, establishments must identify the intended use for consumers of the finished product (9 CFR 417.2(a)(2)). When identifying the intended use, establishments should consider whether chicken liver will be sold to foodservice entities that prepare p\u00e2t\u00e9 or similar dishes and consider the potential hazards that could result from inadequate cooking at foodservice entities. Official establishments that sell chicken liver to foodservice entities should consider any contractual controls that can be put in place to ensure customers will prepare the liver in a manner whereby pathogens would not be a significant health risk. Establishments that do not know the intended use of the chicken liver should consider the possibility that the liver will be used to prepare p\u00e2t\u00e9 or similar dishes and the hazards that could result from inadequate cooking. As described below, freezing, washing with organic acids, proper labeling, and other interventions may help establishments address these hazards. Freezing Studies have demonstrated that freezing can reduce, but not eliminate, Campylobacter contamination of chicken liver. In a study involving homogenized chicken liver, Harrison et al. (2013) found that freezing caused significant reductions in Campylobacter counts. In liver placed in a freezer set at 5 \u00b0F (-15 \u00b0C), Campylobacter counts were reduced by approximately 0.8 log after 24 hours or by approximately 1.5 log after 7 days. Campylobacter counts more rapidly decreased in liver placed in a freezer set at -13 \u00b0F (-25 \u00b0C). An approximately 1.5-

log reduction in Campylobacter counts was achieved after 24 hours; there was no significant difference between this reduction and the 7-day reduction at the same temperature.

Additionally, these researchers observed an overall approximately 3-log reduction in Campylobacter counts after two periods of freezing at -13 °F (-25 °C) for 24 hours separated by a 24-hour thaw at 39.2 °F (4 °C). Baumgartner et al. (1995) found Campylobacter less often in chicken liver that had been frozen, then thawed, than in liver that had not been frozen (16% vs. 31%). These researchers also found that Campylobacter, when present, was generally present in lower numbers in previously frozen chicken liver than in fresh. Freezing the entire liver is likely to affect Campylobacter organisms existing on both the external liver surface and in the internal tissue. 3", "FSIS Guideline: Chicken Liver July 2018

Foodservice preparers and consumers may be concerned that freezing chicken liver negatively affects palatability. However, in a study of cooking practices and consumer preferences in the United Kingdom, Hutchinson et al. (2015) observed among consumers an overall sensory preference for chicken liver pâté made from liver that had been frozen. Organic Acid Washes Some antimicrobials have been validated to reduce Campylobacter on the surface of chicken liver. For example, Hutchinson et al. (2015) found that 2-minute washes at 69.8 °F (21 °C) with either 5% lactic or 5% ethanoic (acetic) acid reduced Campylobacter counts on the surface of naturally contaminated chicken liver by ~1.5 log. Any antimicrobial interventions applied by official establishments to chicken liver need to be considered safe and suitable by FSIS. A list of approved antimicrobials can be found in 9 CFR 424.21(c) and in FSIS Directive 7120.1, Safe and Suitable Ingredients Used in the Production of Meat, Poultry, and Egg Products. Although acid washes will likely not be effective in reducing internal pathogen contamination, they may reduce pathogens on the external surface of chicken liver.

**Labeling/Cooking Instructions** FSIS recommends that chicken liver be fully cooked because freezing and organic acid washes can reduce, but not eliminate, pathogens. For this reason, FSIS recommends that labels of all chicken liver include validated cooking instructions that are sufficient to destroy pathogens. FSIS recommends that cooking instructions indicate that the product should be cooked to a safe minimum internal temperature of 165 °F (73.9 °C), or other validated time/temperature combination, as measured with a food thermometer. This recommendation is consistent with the cooking recommendations in the (Food Code, 3-401.11). In addition, if the product appears ready-to-eat (RTE), but is not (e.g., because chicken liver is broiled, but not fully cooked to lethality, it appears RTE), the label needs to have features that are conspicuous so that the intended user is fully aware that product must be cooked for safety. This is best conveyed through language on the principal display panel of the label (e.g., "cook and serve," needs to be fully cooked," see cooking instructions, or "cook before eating"). In a 2011 outbreak of salmonellosis involving 190 reported illnesses associated with chicken liver products (Hanson et al., 2014), potentially misleading labeling (i.e., "broiled") and product appearance may have given the impression that the product was fully cooked when, in fact, it was not. FSIS requires raw meat and poultry products (including those that are partially cooked) to be labeled with safe handling instructions (9 CFR 317.2(k) and 9 CFR 381.125(b)). In addition, if it is not obvious the product is raw, based on appearance, FSIS recommends establishments include other cues on the label, such as those mentioned in the paragraph above, to increase consumer awareness that the product needs to be 4", "FSIS Guideline:

Chicken Liver July 2018 cooked. Other Interventions Additional interventions listed in the Draft FSIS Compliance Guide for Controlling Salmonella and Campylobacter in Raw Poultry, such as high-pressure processing (HPP), may also be effective in controlling pathogens in chicken liver. Generally, HPP has been found effective in reducing pathogen contamination in other chicken parts; however, FSIS is not aware of any published reports of its effectiveness specifically in chicken liver. Therefore, if an establishment uses HPP to support decisions in its hazard analysis related to pathogen reduction in chicken liver, it would need to gather its own scientific support to meet the validation requirements in 9 CFR 417.4(a)(1). Does this guideline apply to liver from other species? This document is specific to chicken liver. However, illness outbreaks associated with the liver of other poultry species, including goose and duck, have been reported; the recommendations contained in this document may also be effective for other species. DOI <http://askfsis.custhelp.com/FSIS/USDA/www.fsis.usda.gov/2018-9>],{"file\_name":"FSIS\_GD\_2018\_0010","title":"Trichinella\Fresh Raw Pork Products\Consumer Cooking Practices\Supporting Hazard Analysis Questions & Answers","num":"FSIS-GD-2018-0010","id":"83dc66bd7efa3f1fe8e83ec6b27f641ca011f4d11e121b588104428e41064ce7","corp\_us":"fsis\_guidelines","source\_page\_url":"https://www.fsis.usda.gov/policy/fsis-guidelines","url":"https://www.fsis.usda.gov/sites/default/files/import/7320.1-Trichinae-QA.pdf","type":"pdf","n\_pages":3,"word\_count":750,"text\_by\_page":["Subject: Trichinella\Fresh Raw Pork Products\Consumer Cooking Practices\Supporting Hazard Analysis Question: FSIS has removed prescriptive requirements for Trichinella treatment and establishments now have the flexibility provided by the Hazard Analysis and Critical Control Point (HACCP) regulations (9 CFR part 417) to develop appropriate sciencebased controls and preventive measures for Trichinella and other parasitic food safety hazards in pork. Establishments producing pork products should assess in their hazard analysis to determine if Trichinella and other parasites are hazards reasonably likely to occur (RLTO) or not reasonably likely to occur (NRLTO) in their processes. The prescriptive requirements in 9 CFR 318.10 were removed because the regulations were inconsistent with the HACCP regulations. How should establishments consider consumer cooking practices when addressing controls for Trichinella in their HACCP systems for raw products that are customarily safely prepared by consumers? Answer: FSIS anticipates that there will be little to no change for establishments as they were previously required to address Trichinella in their hazard analysis before the implementation of

the final rule \u201cElimination of Trichinæ Control Regulations and Consolidation of Thermally Processed, Commercially Sterile Regulations\u201d (83 FR 25302). The final rule became effective July 30, 2018. Raw and undercooked pork products may present a public health risk when consumed. Of concern, are those pork products: \u2022 Prepared in such a manner that the product might be eaten rare or without thorough cooking because the appearance of the finished product makes it hard for the consumer to visually determine if the product has been fully cooked. Such pork products include ground meat mixtures including those containing pork and beef as well as pork and other ingredients; poultry products containing pork muscle tissue; bacon wrapped products; breaded pork; raw marinated pork in dark sauces; pork products containing ingredients such as annatto, red wine, paprika, red pepper, etc. that can alter the appearance; cured pork; and cured and smoked pork. ; and \u2022 Prepared from feral swine that have an increased risk of infection with *Trichinella*. . When the pork products described above are not cooked at a sufficient internal temperature, any *Trichinella* present may not be destroyed and these products are therefore not rendered safe under normal consumer preparation practices. .This is not the case for all raw fresh pork products, specifically those that are customarily wellcooked in the home or elsewhere before being served to the consumer. Such products include fresh pork from market swine, including fresh unsmoked sausage containing", "pork muscle tissue, and bacon and jowls that were previously listed in 9 CFR 318.10(a). These products are usually prepared at an internal cooking time and temperature combination sufficient to destroy *Trichinella* throughout the product (e.g., 145\u00b0 F for 3 minutes), which renders the product safe under normal consumer preparation practices. If determined to be NRTLTO, an establishment may support this decision in the aforementioned raw fresh pork products by justifying that they are customarily wellcooked as described in Chapter I., Section III., C. of FSIS Directive 7320.1, Prevention and Control of *Trichinella* in Pork Products.", "Subject: *Trichinella*\u201c/Fresh Raw Pork Products\u201d/Noncompliance Question: Should FSIS inspection program personnel (IPP) document a noncompliance record (NR) when an establishment has determined that *Trichinella* is NRTLTO in fresh raw pork products from market swine and has justified the decision because those products are customarily well-cooked and the product bears Safe Handling Instructions (SHIs)? No. Establishments may determine that *Trichinella* is NRTLTO in fresh raw pork products produced from market swine, only if they have support that the product(s) are customarily well-cooked in the home or elsewhere before being served to the consumer. Such products include fresh pork, including fresh unsmoked sausage containing pork muscle tissue, and bacon and jowls that were previously listed in 9 CFR 318.10(a). If *Trichinella* is determined to be NRTLTO in an establishment\u2019s hazard analysis, IPP are to review the decisions made and determine whether supporting documentation is on file to comply with 9 CFR 417.5 (a)(1), and whether that documentation supports the decisions made in the hazard analysis. Support may include consumer preparation practices, such as SHIs or special handling\u201c/descriptive cooking instructions to ensure their customers will prepare the product in a manner that is customarily well-cooked. If IPP have questions after reviewing FSIS Directive 7320.1, Prevention and Control of *Trichinella* in Pork Products, regarding the adequacy of the establishment\u2019s support, they are to seek guidance from their immediate supervisor or an Enforcement, Investigation, and Analysis Officer (EIAO) to determine whether there is a basis to question the adequacy of support for the hazard analysis."], {"file\_name": "FSIS\_GD\_2018\_0011", "title": "FSIS"}]

Establishment Eligibility Criteria for the Salmonella and Campylobacter Verification Sampling Program and FSIS Scheduling Algorithm for the Salmonella and Campylobacter Verification Sampling Programs for Raw Poultry","num":"FSIS-GD-2018-0011","id":"c03ccde8d433864ac640dda3ec43b0a157d25ba67f0082ab528098a13c308029","corpus":"fsis\_guidelines","source\_page\_url":"https://www.fsis.usda.gov/policy/fsis-guidelines","url":"https://www.fsis.usda.gov/sites/default/files/import/Salmonella\_Scheduling\_Algorithm\_Functions.pdf","type":"pdf","n\_pages":4,"word\_count":1254,"text\_by\_page":[{"1 FSIS Establishment Eligibility Criteria for the Salmonella and Campylobacter Verification Sampling Program1 and FSIS Scheduling Algorithm for the Salmonella and Campylobacter Verification Sampling Programs for Raw Poultry Introduction FSIS assesses establishment performance for various poultry products against performance standards published in the Federal Register. In particular, the Salmonella and Campylobacter standards are assessed for young chicken carcasses, comminuted chicken, chicken parts (specifically legs, breasts, and wings), young turkey carcasses, and comminuted turkey. FSIS assigns samples for various poultry products each month under the Salmonella and Campylobacter Verification Sampling Programs for Raw Poultry through the Public Health Inspection System (PHIS). This is known as routine sampling2. The establishments and products selected monthly for sampling are chosen according to an algorithm from a list of eligible establishments and their respective products. These are the criteria used to create a list of establishments and products that are eligible for inclusion in the Salmonella and Campylobacter Verification Sampling Program, and the methods used to assign establishments for sampling. Only the five product classes above have performance standard criteria and are assigned samples under routine sampling. For those establishments that do not pass the performance standard follow-up samples can be assigned as well. FSIS does test other poultry products such as mechanically-separated chicken, mechanically-separated turkey, and chicken parts other than legs, breasts and wings under exploratory projects. This document specifically describes how establishments are determined to be either eligible or ineligible for testing and how the algorithm for assigning routine and follow-up samples to establishments specifically for products under performance standards operates. Eligibility Criteria and the Sampling Frame The Salmonella and Campylobacter Verification Sampling Program currently schedules five (5) different poultry product classes for routine sampling: Young Chicken Carcasses, Young Turkey Carcasses, Ground or other Comminuted Chicken, Ground or other Comminuted Turkey, and Chicken Parts (specifically, legs, breasts, and wings). Eligibility requirements for the Poultry Carcasses differ from the Raw Comminuted Poultry Products and from the Raw Chicken Parts. The first step in the scheduling process is to assemble the sampling frame, which is the list of eligible establishments and their respective products. An establishment's HACCP size does not factor into its eligibility. I. Establishments Producing Eligible Product a. The first step is to create a list of all establishments that produce sufficient volumes of eligible products. Currently, the smallest-volume producers are excluded (as defined below) from the program, as are ineligible products such as mechanically-separated chicken or turkey and raw product intended to be made into a ready-to-eat (RTE) product. 1 This includes Salmonella and Campylobacter testing for Raw Young Chicken Carcasses, Raw Young Turkey Carcasses, Raw Ground or Other Comminuted Chicken, Raw Ground or Other Comminuted Turkey, and Raw Chicken Parts. 2 Defined in 81 FR 3940 and 81 FR 7285."}, {"2 b. Intact Raw Poultry Carcasses a. Using slaughter volume data recorded in

PHIS, the total heads of young chickens and young turkeys slaughtered at FSIS establishments over the last 12 months is collected. Based on data from a PHIS questionnaire, the proportion of birds slaughtered under a religious exemption is excluded from the total production in determining an establishment's eligibility. For example, if an establishment slaughters 30,000 young chickens over the course of a 12-month period, but the questionnaire indicates 50 percent are slaughtered under a religious exemption, then the production estimate used to determine eligibility is 15,000 birds. Such an establishment would not be eligible for sampling in the Verification Program. Establishments that meet the minimum production volume requirements are further evaluated in the next step. The current minimum production volume to be included is:

- 1. Young Chickens: minimum of 20,000 heads slaughtered per year
- 2. Young Turkeys: minimum of 20,000 heads slaughtered per year
- c. Raw Chicken Parts a. Establishments whose establishment profiles indicate they produce at least the minimum volume of chicken legs, breasts, or wings are eligible for Salmonella and Campylobacter Verification Sampling. The current minimum production volume to be included is 1,001 pounds per day.
- d. Raw Ground and Other Commminuted Poultry a. Establishments whose PHIS profiles indicate they produce at least the minimum volume of ground or other comminuted (but not mechanically separated) chicken or turkey are eligible for sampling in the Salmonella and Campylobacter Verification Program. The average daily raw ground or comminuted chicken or turkey production volume listed in the establishment profile is used to determine whether an establishment meets minimum production volume requirements:

  - 1. Raw Ground Chicken: minimum of 1,001 pounds produced per day.
  - 2. Raw Ground Turkey: minimum of 1,001 pounds produced per day.

- II. Active Establishments a. The second step is to eliminate establishments that are not currently listed as active in their profiles, with one exception. If an establishment is inactive, but produced product within the last 12 months, samples may be scheduled on occasion to ensure seasonal producers are scheduled for sampling. Otherwise, establishments that are shut down, withdrawn from inspection, or otherwise not producing product are removed from eligibility.
- III. Scheduling Algorithm a. Once the sampling frame has been assembled, the list of eligible establishments and their respective products is weighted by production volume and past rates of Salmonella-positive product across all establishments in that product's production volume category, where available. The total number of samples allotted to each project is then assigned across establishments, with replacement, using these weights. FSIS intends to schedule at least the minimum number of samples per year per product published in 81 FR 7285 for as many establishments as practicable.
- b. If an establishment produces multiple eligible types of products tested in separate FSIS sampling projects, these products are scheduled independently. Assignment of samples in multiple eligible product types and projects is expected in such establishments. However, a ceiling exists so that no establishment is assigned more than five (5) samples per sampling project.
- IV. Scheduling Follow-up Samples Establishments that do not meet the Salmonella performance standard in poultry carcasses are assigned samples in the corresponding follow-up sampling project(s). Raw chicken parts, raw ground or otherwise comminuted chicken, and raw ground or otherwise comminuted turkey follow-up sampling projects are expected to begin later in 2018. Follow-up samples are included in establishment category determinations. The details of this sampling are summarized below.
- a. When any establishment is identified as having failed to meet the Salmonella standard in either young chicken or young turkey carcasses, it is assigned 8 or 16 follow-up

samples from the associated product as described in FSIS Notice 01-18. These follow-up samples are in addition to routine samples. b. When an establishment moves out of Category 3, it will continue to be scheduled for routine samples under the sampling algorithm as described in section III. If it subsequently fails to meet the standard, follow-up samples will once again be scheduled.

V. Exploratory Sampling

a. FSIS published in 81 FR 7285 that the agency would begin testing establishments that:

- i. produced product under a religious exemption, or
- ii. did not produce the minimum amount of product listed in Section I of this document.

b. These establishments are currently excluded from performance standard testing. Sampling of these establishments was implemented in Fiscal Year 2017 under new exploratory sampling projects to begin gauging the levels of pathogens in these populations, as addressed in FSIS Notice 27-17.

c. FSIS currently samples certain poultry products that are not included under performance standards in exploratory sampling projects. These products include mechanically-separated chicken, mechanically-separated turkey, and chicken parts", "4 other than legs, breasts, and wings. The eligibility criteria and sampling algorithm are not described here for those projects."]}, {"file\_name": "FSIS\_GD\_2019\_0001", "title": "How to Request Duplicate Copies of Approved Labels", "num": "FSIS-GD-2019-0001", "id": "40fe2ff38ecdaef7590a78ff577bf17665a8532bc5422a18283e63afadb95d47", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/import/Requesting\_Approved\_Label\_Copies.pdf", "type": "pdf", "n\_pages": 1, "word\_count": 289, "text\_by\_page": ["HOW TO REQUEST DUPLICATE COPIES OF APPROVED LABELS Revised April 10, 2019 In order to receive copies of your labels which have been approved by the Labeling and Program Delivery Staff (LPDS), please MAIL your request on COMPANY LETTERHEAD, an ORIGINAL, DATED, and SIGNED LETTER (no copies) with the following information: 1) The complete product name for each meat and\or poultry product needed, 2) The dates for which the labels were approved, 3) The establishment number(s), 4) The label approval number, and 5) The reason for the request If you are using an expeditor firm or other agent on your behalf and wish this information to be mailed or picked up by them, please indicate that information in the letter as well. Safety and Inspection Service Labeling Guideline on Statements That Bioengineered or  
Genetically-Modified Ingredients or Animal Feed Were Not Used in Meat, Poultry, or Egg  
Products December 2019 This guideline is designed to help establishments that want to make  
labeling claims about: \u2022 Whether Bioengineered or Genetically- Modified Ingredients  
were not used in Meat Poultry, or Egg Products. \u2022 Whether a product was produced from  
livestock or poultry that were not fed bioengineered or geneticallymodified feed. 1","I. Purpose  
This document provides guidance for companies that want to make label or labeling claims  
concerning the fact that bioengineered or genetically-modified (GM) ingredients were not used  
in a meat, poultry or egg product. This guidance also provides information on how companies  
can make label or labeling claims that a product was produced from livestock or poultry that  
were not fed bioengineered or GM feed. For purposes of this guidance document, these claims  
will be referred to as \u201cnegative claims.\u201d This version of the Guideline replaces the  
version that published in August 2016. FSIS solicited comments on the previous version. Many  
of the issues raised in the more substantive comments were about how the statutory definition  
of \u201cbioengineering\u201d in Pub. L. 114-216 should be interpreted and applied. FSIS  
believes these comments are beyond the scope of this guidance. However, the same issues  
were raised as responses to questions posted in 2017 by the Agricultural Marketing Service  
(AMS) as part of the development of the proposed National Bioengineered Food Disclosure  
Standard (NBFDS). On December 21, 2018, AMS addressed these and other issues in the NBFDS  
final rule (83 FR 65814). In response to other comments, FSIS has updated the guideline to  
clarify that it approves negative claims verified under a thirdparty certifying organization  
consistent with how it approves other special statements or claims and by adding information  
about the certification and labeling for certified-organic products. Although comments will no  
longer be accepted through www.regulations.gov on this guidance, FSIS will update this  
document as necessary if new information becomes available. II. Congressional Review Act  
Pursuant to the Congressional Review Act at 5 U.S.C. 801 et seq., the Office of Information and  
Regulatory Affairs has determined that this guideline is not a \u201cmajor rule,\u201d as  
defined by 5 U.S.C. 804(2). III. Background FSIS approves negative claims through its prior label  
approval process. Because FSIS does not have the ability to independently verify negative  
claims for ingredients or feed, FSIS has required establishments that make these claims to  
comply with standards established by a thirdparty certifying organization. FSIS also requires  
that the third-party\u2019s standards be publicly available on a website and that the label or  
labeling disclose the website address of the thirdparty organization.1 FSIS requires that the

establishment demonstrate that its claims of thirdparty certification are truthful and not misleading in accordance with 9 CFR 317.8 or 381.129. As a policy matter, FSIS has allowed the use of the terms \u201cgenetically modified organism\u201d or \u201cGMO\u201d on product labels or labeling only if the name of the third-party certifying organization contains these terms (e.g., \u201cNon-GMO Project\u201d). However, as mentioned above, recent 1 Products certified as \u201corganic\u201d would not need to disclose a website address on the label, except when the address is required under 7 CFR Part 205. 2", "----\_) legislation was enacted (Pub. L. 114-216) requiring the Secretary of Agriculture to develop and implement a mandatory NBFDS. This legislation also addresses negative claims, providing that: \u2022 \u201cThe definition of \u2018bioengineering\u2019 under Section 291 shall not affect any other definition, program, rule, or regulation of the Federal government\u201d (Pub. L. 114-216, Sec. 292. Applicability); \u2022 \u201cA food may not be considered to be \u2018not bioengineered\u2019, \u2018non-GMO\u2019, or any other similar claim describing the absence of bioengineering in the food solely because the food is not required to bear a disclosure that the food is bioengineered under this subtitle\u201d (Pub. L. 114-216, Section 294. Savings provisions); and \u2022 In the case of a food certified under the USDA organic regulations, the certification \u201chall be considered sufficient to make a claim regarding the absence of bioengineering in the food, such as \u2018not bioengineered\u2019, \u2018non-GMO\u2019\u201d or other similar claim in accordance with the USDA organic regulations (Pub L. 114-216, Sec. 2. Organically produced food). Accordingly, FSIS reconsidered its past position. In 2016, FSIS began allowing the use of the terms \u201cgenetically modified organism\u201d or \u201cGMO\u201d in negative claims as long as the label or labeling is otherwise truthful and not misleading. At this time, FSIS approves negative claims that contain the terms \u201cgenetically modified organism\u201d or \u201cGMO\u201d for meat, poultry and egg products that do not contain bioengineered ingredients and\or that are derived from livestock or poultry that do not consume bioengineered feed when substantiated with evidence of compliance with standards verified by a third-party certifying organization. FSIS does not define \u201cbioengineered.\u201d Instead, FSIS relies on third-party certifiers to verify that products meet their standards for the absence of bioengineered or nonGMO material. The certifier can utilize either the AMS\u2019s definition of \u201cbioengineering\u201d in Pub. L. 114-216 or the U.S. Food and Drug Administration\u2019s (FDA\u2019s) definition of \u201cmodern biotechnology.\u201d FSIS also will continue to allow the use of synonymous terms such as \u201cgenetically engineered\u201d or \u201cGE.\u201d In evaluating such claims, FSIS will verify their accuracy. Consistent with our longstanding practice for other special statements and claims, if an official Key Point establishment submits documentation demonstrating The following are documentation needed to that the third-party certifying organization\u2019s program substantiate a negative claim: for a particular negative claim is being followed, 1. A current copy of the third-party FSIS will allow the claim on their labels. certificate; and 2. A written description for the IV. EXAMPLES OF LABEL identification, control, and segregation of conforming and non-conforming CLAIMS animals or products, except when these activities are a condition of Examples of negative claims for the meat or poultry certification. component that was raised on feed containing nongenetically modified ingredients that FSIS would accept include, but are not limited to: \u201cPasture raised beef fed a vegetarian diet with no 3", "bioengineered ingredients,\u201d \u201cChicken raised on a

diet containing no genetically engineered ingredients,\u201d or \u201cDerived from beef fed no GMO feed.\u201d NOTE: See label example 1 With respect to acceptable claim terminology for multi-ingredient products, examples of negative claims FSIS would accept include, but are not limited to: \u201cContains No GMO ingredients,\u201d \u201cNo genetically modified ingredients,\u201d \u201cIngredients used are not bioengineered,\u201d or \u201cNo genetically engineered ingredients through the use of modern biotechnology.\u201d NOTE: See label example 2 Noting the aforementioned website exception for certified organic foods, negative claims will be approved only if the third-party certifying organization is identified on the label and the labeling discloses a website address where consumers can obtain additional information regarding the claim and the certification process. This information must be connected to the negative claim by an asterisk or other symbol and include an explanatory statement, e.g., \u201cProduced in accordance with [certifying entity]\u2019s standards\u201d or \u201cCertified by [certifying entity].\u201d A USDA-accredited organic certifier is one example of a third-party certification organization. For products that qualify for an \u201corganic\u201d claim under the USDA organic regulations, establishments are not required to provide FSIS with additional documentation for approval of negative claims. The USDA organic regulations (7 CFR Part 205) prohibit the use of geneticallymodified organisms in the production and handling of an organic product. Furthermore, certified-organic products must be derived from animals that did not consume feed or feed supplements that contain genetically-modified organisms. Therefore, a current Organic Certificate is sufficient documentation to support a negative claim. Any negative claims on products labeled as \u201corganic\u201d must be connected by an asterisk or other symbol to the explanatory statement: \u201cProduced in compliance with the USDA Organic Regulations.\u201d NOTE: See label example 3 LABEL APPROVAL SUBMISSION Negative claims are \u201cspecial statements and claims\u201d as defined in 9 CFR 412.1(e) and cannot be generically approved unless previously approved in the manner described in the section below. Therefore, establishments are required to submit labels with negative claims to FSIS for prior approval before using them on labels or labeling (9 CFR 412.1(c)(3)). GENERIC APPROVAL FOR CERTAIN LABELS For meat, poultry or egg products with negative claims that FSIS has previously approved, the establishment is allowed to change the terms \u201cnon-genetically engineered\u201d or \u201cnon-GE\u201d to \u201cnonGMO\u201d or \u201cno genetically modified organisms\u201d without prior-approval from FSIS. Such changes 4", "Natural\*\* Raised without Added Antibiotics \"\"Minimally Processed, No Artificial Ingredients ~Coal,~. a~~-::---~ Distributed by A Good Win! Farmstl 1224 Unique Or. 23 2","This document follows the procedures for guidance documents in the Office of Management and Budget\u2019s (OMB) \u201cFinal Bulletin for Agency Good Guidance Practices.\u201d More information can be found on the Food Safety and Inspection Service (FSIS) webpage:  
<https://www.fsis.usda.gov/wps/portal/footer/policies-and-links/significantguidance-documents>. This is the revised version of the document titled FSIS Guidance: Modernization of Swine Inspection System -Microbiological Sampling in Swine Slaughter Establishments and reflects comments received during the comment period for the Modernization of Swine Slaughter Inspection Proposed Rule. This guideline represents FSIS\u2019s current thinking on this topic. FSIS encourages establishments to use it to comply with requirements that apply to all establishments that slaughter swine. The information in this guideline is provided to assist swine slaughter establishments (especially small and very small) and is not legally binding from a regulatory perspective. Purpose of this Guideline The purpose of this guideline is to assist all swine slaughter establishments, regardless of swine class, to comply with new microbiological sampling and analysis requirements that apply to all official swine slaughter establishments as published in the final rule \u201cModernization of Swine Slaughter Inspection.\u201d Establishments may also find the information in this guideline helpful for developing their sampling plan programs prior to the implementation of the final rule. Note that this guideline includes a list of references as additional resources on technical concepts specific to the development of a microbiological sampling plan. An establishment can always seek guidance from State HACCP contacts, coordinators and University extension specialists on developing and maintaining written sanitary dressing procedures, developing a written microbiological sampling plan, developing sample collection procedures, and using statistical process control to evaluate process control. Changes from Previous Version FSIS made changes throughout the guideline to clarify information and recommendations. In addition, FSIS made the following specific changes to the guideline to reflect changes in the final rule and comments received during the comment period for the proposed rule: 3"," \u2022 Removed the word \u201ccompliance\u201d from the document title and throughout the document to clarify that this document does not constitute regulatory requirements. \u2022 Removed all references to pre-operational environmental sampling, consistent with changes to the final rule. \u2022 Moved example control charts to Appendix 2 and clarified the recommendations for using such control charts without defining the specific format for displaying the data. \u2022 Added Table 2 -Indicator Organism Optional Upper Control Limits for Market Hog Carcasses to replace the previous Table 4 -Indicator Organism Geometric Mean Values for Market Swine, providing better guidance for establishments that may want to use data from the 2011 FSIS Market Hog Baseline Survey to set their upper control limits. Questions Regarding Topics in this Guideline

FSIS recommends that users who have questions regarding the information covered in this guideline search the publicly posted Questions & Answers (Q&As) in the askFSIS database or submit questions through askFSIS. Documenting these questions helps FSIS improve and refine present and future versions of the guideline and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter Swine Modernization Sampling Guideline. Question Field: Enter question with as much detail as possible. Product Field: Select General Inspection Policy from the drop-down menu. Category Field: Select Sampling from the drop-down menu. Policy Area: Select Domestic (U.S.) Only from the drop-down menu. When all fields are complete, press Continue. 4", "FSIS Guideline: Modernization of Swine Slaughter Inspection Developing Microbiological Sampling Programs in Swine Slaughter Establishments Microbial Sampling Requirements Addressed by this Guideline Livestock, including swine, have been identified as reservoirs for pathogens. The intestinal tract, mouth, skin, and hooves of swine can contain pathogens. Pathogens can be transferred to the carcass during the slaughter process and to pork parts throughout processing. Slaughter establishments typically employ a variety of controls to prevent, eliminate, or reduce pathogens during slaughter and processing. In the food production environment, \u201ccontrol measures can be applied to prevent an unacceptable increase in a hazard, eliminate it, or reduce it to an acceptable level\u201d (Scientific Criteria to Ensure Safe Food. IOM, 2003). Under Hazard Analysis and Critical Control Points (HACCP) regulations, an establishment is required to have controls in place to properly monitor and maintain its food safety system. Controls includes process control procedures supported by science-based standards that prevent, eliminate, or reduce biological, chemical, and physical hazards. An establishment can determine if the food safety system demonstrates either effective process control or loss of process control by analyzing the measurable attributes that are tailored to its system. One means for establishments to verify whether they maintain process control is through microbiological testing for indicator organisms.

Microbiological sampling and testing identify the presence of enteric pathogens in the context of the establishment\u2019s production process and processing steps, thus providing a microbiological measure of process control in addition to observation of carcasses and parts to detect visible contamination. Through statistical process control, an establishment defines what, in this context, are its control limits (i.e., upper and lower control limits) for indicator microorganisms. Process Control Procedures and Measurable Science-Based Parameters An establishment should design its operating conditions to meet defined food safety outcomes. This includes process control procedures and measurable science-based standards that affect establishment operating conditions. An establishment\u2019s process control procedures may include: \u2022 Sanitary dressing procedures effectively implemented to prevent carcass contamination and to minimize cross-contamination; \u2022 Procedures for decontamination of carcasses that become contaminated; \u2022 Procedures to prevent the creation of insanitary conditions; 5", "\u2022 Antimicrobial intervention treatments; and \u2022 Implementation of other best practices (e.g., those described in FSIS guidance documents). An establishment\u2019s measurable science-based standards or parameters may include: \u2022 Sanitary dressing monitoring; \u2022 Zero tolerance for visible contamination checks; \u2022 Microbiological testing results, for indicator organisms (e.g., Aerobic Plate Counts (APC), Enterobacteriaceae (EB), generic E. coli, total coliforms) and pathogens (e.g., Salmonella); and

\u2022 Critical operational parameters for antimicrobial interventions (e.g., concentration, pH, temperature). These procedures and parameters should be incorporated into the establishment\u2019s HACCP plan, sanitation standard operating procedures (sanitation SOPs), or other prerequisite programs (collectively referred to as the establishment\u2019s HACCP system). Requirements for Written Procedures and Microbiological Sampling Under the final rule to modernize swine slaughter inspection, all swine slaughter establishments, regardless of swine class, are required to develop, implement, and maintain written procedures to prevent contamination of carcasses and parts by enteric pathogens, and visible fecal matter, ingesta, and milk throughout the entire slaughter process and dressing operation. FSIS recommends establishments consider potential contamination sources, such as incised lymph nodes, intestinal rupture, and stick wounds, when designing its sampling plan (Garrido 2014, Vieira-Pinto 2005, Bonardi 2013). To demonstrate the effectiveness of such procedures in their food safety systems, all swine slaughter establishments are required to sample and test for microbial organisms at prescribed locations and frequencies, and to analyze the results obtained to assess the establishment\u2019s ability to maintain process control. Swine slaughter establishments are required to incorporate their written procedures, including their microbiological sampling plans, into their HACCP system. The final rule modernizing swine slaughter requires all swine slaughter establishments to:

\u2022 Develop, implement, and maintain written procedures to prevent contamination of carcasses and parts by enteric pathogens and fecal material throughout the entire slaughter and dressing operation. To demonstrate effectiveness of such procedures using their HACCP system (i.e., HACCP plan, sanitation SOPs, or other prerequisite programs), establishments are required to sample for microbial organisms and analyze results at prescribed locations and frequencies to assess the establishment\u2019s ability to maintain process control.

6", "Predominant Species:

Establishments that slaughter more than one type of livestock must test the type of livestock slaughtered in the greatest number. \u2022 Incorporate their written procedures, including their microbiological sampling plans, into their HACCP system (i.e., HACCP plan, sanitation SOPs, or other prerequisite programs).

\u2022 Maintain records associated with these procedures.

**Microbial Sampling Plan for Carcasses**

The final rule removed the requirement that swine slaughter establishments sample and test carcasses for generic Escherichia coli (E. coli Biotype I) to monitor process control and removed the codified Salmonella pathogen reduction performance standards for hogs and replaced them with the new sampling and testing requirements. The new sampling and testing requirements allow an establishment to develop a sampling plan that is tailored to its process and, consequently, allows for more effective monitoring of process control than the current generic E. coli criteria. An establishment that slaughters swine should determine which microbial organism(s) will be most effective in assessing its process control when developing its sampling plan. Each establishment has a configuration and process unique to the facility, the food safety system in place, and the hazards deemed reasonably likely to occur. Appendix 1 highlights the key elements that an establishment should address as part of its written microbiological sampling plan and can be used by an establishment as a self-assessment tool. FSIS recommends that an establishment choose one or more indicator organism that will provide meaningful data in assessing process control. Potential indicator organisms include APC, EB, generic E. coli, and total coliforms. FSIS recommends an establishment use APC because it is less specific than generic E. coli and

provides more quantifiable data. Enumeration allows an establishment to plot these data on a process control chart and monitor trends in its data and process over time. The more quantifiable microbiological data available to an establishment, the better it can assess and subsequently control variations in its process (Williams 2015). In contrast, generic E. coli is a smaller group (subset) of the Enterobacteriaceae family of bacteria; analysis of samples for generic E. coli often results in numerous non-detectable results (\u201czero values\u201d) which makes it difficult for an establishment to detect changes in microbial load at different points in establishment\u2019s process, and to identify trends in its data to make process control decisions. Sampling Frequency Under the final rule, swine slaughter establishments, except for very low volume (VLV) establishments, will be required to collect pre-evisceration and post-chill carcass samples at a frequency of one sample each per every 1,000 head slaughtered. As described in the preamble of the rule, VLV establishments are those which annually 7", "slaughter no more than 20,000 swine, or a combination of swine and other livestock not exceeding 6,000 cattle and 20,000 total of all livestock. As is stated in the preamble to the final rule, establishments that slaughter more than one type of livestock must test the type of livestock slaughtered in the greatest number. Establishments must analyze one carcass sample at pre-evisceration and one carcass sample at post-chill per sampling event; these samples do not need to be from the same carcass. Samples must be collected and analyzed at a frequency of once per 1,000 carcasses, with a minimum of one sampling event during each week of operation. VLV swine slaughter establishments, starting June 1 of every year, are required to take a minimum of one post-chill carcass sample per sampling event during each week of operation. If, after consecutively collecting and testing 13 weekly carcass samples, VLV establishments can demonstrate that they are not exceeding their upper control limit for microbial organisms and that they are effectively maintaining process control, they can modify their sampling plans to collect carcass samples less frequently. VLV establishments that slaughter swine and are operating under traditional inspection may choose to continue conducting generic E. coli testing at post-chill to meet the sampling requirements in the final rule. FSIS considers the requirements under the former regulations for generic E. coli testing of swine to be a \u201csafe harbor\u201d for assessing process control. Former provisions that FSIS considers to be integral to that safe harbor include the following: A. Testing for generic E. coli, FSIS requires an establishment to collect a series of 13 samples, at a minimum, to be able to assess process control. B. To collect the sample, the establishment must collect an excision or swab sample of the ham, belly, and jowl from the carcass at the end of the chilling process. FSIS Guideline: Guidelines for Escherichia coli Testing for Process Control Verification in Cattle and Swine Slaughter Establishments provides more detailed guidance on the sampling procedures. C. Laboratories analyzing the samples should use a quantitative method for generic E. coli analysis that is approved and published: 1) as an official method of the Association of Official Analytical Chemists International (AOAC International) or 2) by a scientific body based on the results of a collaborative trial conducted in accordance with an internationally recognized protocol on collaborative trials and compared against the three-tube Most Probable Number Definitions Pre-evisceration refers to the location early in the slaughter process prior to evisceration of the hog. Post-chill refers to a later point in the slaughter process after carcasses are chilled and all interventions have been applied prior to fabrication. 8", "(MPN) method; this type of method must also agree with the 95 percent upper and lower confidence

limits of the appropriate MPN index (9 CFR 310.25(a)(3). Performance criteria are those that represent the highest expected microbial loads on carcasses when the slaughter process is under control. The generic E. coli baseline results, using the surface swab sampling technique, can serve as support to establishments that slaughter swine in assessing the effectiveness of their process, using their own test results (70 FR 8058). An establishment may also choose to use the generic E. coli performance criteria defined in the Pathogen Reduction: Hazard Analysis and Critical Control Point (HACCP) Systems; Final Rule, also see Table 1 below, for samples collected using an excisional collection method. These generic E. coli performance criteria have been separated into three categories for process control verification: acceptable, marginal, and unacceptable. In the Pathogen Reduction\HACCP Regulation, \u201cm and M\u201d represent the 80th and 98th percentile of sample results, respectively, leaving 18 percent of the results in the marginal range based on the upper limits for the acceptable and marginal ranges. An establishment is considered to be operating within the criteria when the most recent generic E. coli test result does not exceed the upper limit (M), and the number of samples, if any, testing positive at levels above (m) is three or fewer out of the most recent 13 samples (n) taken, as follows:

Table 1. Performance Criteria for Generic E. coli for Swine Carcasses Using Excisional Sampling	Lower limit of marginal range (m)	Upper limit of marginal range (M)
Number of Samples tested (n)	Maximum number permitted in the marginal range	10 CFU/cm <sup>2</sup>
10,000 CFU/cm <sup>2</sup>	13	Because each swine slaughter establishment will determine which microbial organism(s) will be most effective in assessing its process control when developing its sampling plan, additional indicator organism upper control limits are provided in Table 2. The upper control limits in Table 2, were determined from surface swab samples based on the FSIS Market Hog Baseline Study (MHBS) and may be used for all swine species; but establishments are not required to use this table. There may be some variability among swine classes. The information in Table 2 represents the 80th percentile limit for additional indicator organisms. Percentiles represent the percent of establishments that are below the associated number in the distribution of average bacteria indicators per establishment.
9", "APCs Enterobacteriaceae	9", "APCs Enterobacteriaceae	110

5,500	35	3,800 30 Distribution 80% 80% 80% 80% Percentile Table 2. Indicator Organism
Optional Upper Control Limits for Market Hog Carcasses d FSIS MHBS, 2010 \u2013 2011. An establishment should aim for test results below those limits listed for its selected indicator organism at pre-evisceration and post-chill locations. Indicator organism results below the upper control limit shown in Table 2 indicate that the process is in control. FSIS recommends that the establishment plot its data on a control chart to evaluate its test results over time, and to evaluate process control and variability in its food safety system. Additionally, FSIS recommends that establishments monitor the log reduction between pre-evisceration and post-chill as an additional measure to evaluate process control. Example: If an establishment has APC test results above 790 CFU/cm <sup>2</sup> at post-chill, its process is most likely out of control and the establishment should take corrective action to bring its process back under control. (Compliance Guideline for Controlling Salmonella in Market Hogs, page 29). An establishment should evaluate its sampling data at a defined frequency and adjust its upper control limits to lower thresholds to reflect improved process control trends. It is not advisable that an establishment raise its upper control limits in response to upward trends in its sampling data		

since its upper control limits were initially calculated based on its process being in control. Random Selection and Sampling of Carcasses At a minimum, all swine slaughter establishments are required to collect carcass samples at the frequency specified in Table 3. Samples should be collected randomly at the frequency determined by the establishment as part of its sampling plan. If more than one shift is operating at the establishment, the samples can be taken on any shift. Variations have been found from samples collected on different shifts; therefore, it is important that the establishment ensure that all shifts have an equal opportunity to be selected for sampling. An establishment should use a method for selecting a carcass for sampling that 10", "includes the use of random numbers to ensure that sampling is not biased. Examples of methods include random number tables, calculator or computergenerated random numbers, or drawing cards. The sampled carcass should be selected at random. If there are multiple lines, the establishment should randomly select the line for sample collection for that interval. Each line should have an equal chance of being selected at each sampling interval within the relevant time frame. Carcasses should be selected at the identified points in the process. Official swine slaughter establishments, except for VLV establishments, must collect and analyze samples for microbial organisms at the preevisceration (i.e., the location early in the process prior to evisceration of the hog) and post-chill points in the process (i.e., the point in the slaughter process after all slaughter interventions are completed and the carcass has been chilled in the cooler). VLV establishments must collect and analyze samples for microbial organisms only at the post-chill point in the process. Establishments that bone their products before chilling (i.e., hot-boned products) must collect a pre-evisceration sample and a sample after the final wash instead of at post-chill, because these products are not chilled before further processing. All swine establishments must sponge or excise tissue from the ham, belly, and jowl areas.

Following the application of an antimicrobial prior to the point of sample collection, a drip time of at least 60 seconds should be observed before sample collection to reduce antimicrobial carryover in the collected sample. Definitions Hot-bone refers to the process where carcasses (e.g., larger hogs and sows) are immediately deboned after slaughter prior to chilling.

11", "Table 3. Requirements for Microbial Sampling for Indicator Organisms in Swine Slaughter Establishments Establishment Size Based on Volume Microbial Sampling Requirement Very low volume (VLV) (Establishments that annually slaughter no more than 20,000 swine, or a combination of swine and other livestock not exceeding 6,000 cattle and 20,000 total of all livestock.) Starting June 1 of every year, establishments will collect a minimum of one post-chill sample during each week of operation. The sampling plan may be modified after 13 consecutive weekly samples demonstrate effective process control. All other establishments Establishments must analyze 1 sample collected at preevisceration and 1 sample collected at post-chill per sampling event. Samples must be collected at each location and analyzed at a frequency of one per every 1,000 carcasses, with a minimum of one sampling event preevisceration and post-chill during each week of operation. Note that the pre-evisceration and post-chill samples for each sampling event do not need to be taken from the same carcass. As described in Table 3, under the final rule swine slaughter establishments, except for VLV establishments, are required to collect pre-evisceration and post-chill samples at a frequency of one sample each per every 1,000 carcasses. VLV establishments will be required to collect at least one post-chill sample during each week of operation, beginning June 1 each year. If, after collecting 13 consecutive weekly samples, VLV establishments can demonstrate that they are effectively maintaining

process control, they can modify their sampling plans to collect samples less frequently. Pre-Sampling Preparation and Aseptic Technique Extraneous organisms from hands, clothing, sampling equipment, or the processing environment can contaminate samples and lead to erroneous analytical results. Aseptic sampling techniques should be followed to ensure accurate test results that are representative of the product and process. 12", "Before beginning sample collection, it is important to assemble sampling supplies, such as sterile gloves, sterile sampling solutions, and sterile sampling sponges. Sterile sampling solutions, such as buffered peptone water (BPW) broth, should be stored according to the manufacturer\u2019s instructions; however, at least 1 day before sample collection, FSIS recommends that establishments check the solution\u2019s expiration date and other indicators of sterility based on the manufacturer\u2019s instructions. An area should be designated as a staging site for preparing the sampling supplies. An easily sanitized surface, such as a stainless-steel table or wheeled cart, can be used. A small plastic tote may also be useful for transporting sampling supplies to sample collection sites. Sterile gloves should be used when handling sterile sampling equipment (e.g., a sampling sponge) during the sample collection process. Care should be taken to prevent contamination of the external surface of the gloves prior to and during the sample collection process. Sample Analysis The establishment should ensure that the microbiological testing it conducts meets its food safety needs. An establishment needs to determine whether sample analysis will be performed by an outside laboratory or in its own microbiological testing laboratory on-site (if available). Because of the costs and the logistics involved with maintaining an onsite microbiological testing laboratory, an establishment may choose to have its samples analyzed by an outside laboratory. FSIS has made available guidance to aid in the selection of a testing laboratory, Establishment Guidance for the Selection of a Commercial or Private Microbiological Testing Laboratory. This guidance document can assist an establishment when selecting a commercial or private laboratory to analyze its microbiological samples, the method used to analyze samples, and how the results are reported. The establishment should clearly communicate its needs to the testing laboratory and direct it to any necessary testing protocols or other guidance, including this document, that are available on the FSIS website. If an establishment selects a testing laboratory that does not apply appropriate testing methods or effective Quality Control\Quality Assurance (QC/QA) practices, it may not receive reliable or useful testing results to be able to support decisions made in its hazard analysis. The establishment is responsible for ensuring the appropriate analytical methods are used and should convey this information to the laboratory. FSIS has also made available a list of Foodborne Pathogen Test Kits Validated by Independent Organizations for the detection of relevant foodborne pathogens (i.e., *Salmonella*, *Campylobacter*, Shiga toxin-producing *E. coli*, including *E. coli* O157:H7, and *Listeria* spp., including *L. monocytogenes*). This list is updated periodically and is intended to be informational only. The list does not serve as an Agency endorsement or approval of any method or test kit. 13", "FSIS recommends that an on-site microbiological testing laboratory be segregated from manufacturing areas and that access to the laboratory space be limited to prevent cross-contamination and assure the reliability of the test results. If the establishment tests for pathogens on-site, FSIS recommends that it have the following additional safeguards in place to ensure food safety and biosecurity: \u2022 Follow requirements for Biosafety Level II laboratory operations as outlined in Biosafety in Microbiological and Biomedical Laboratories (BMBL); \u2022 Restrict access to the laboratory

to trained staff; and \u2022 Ensure the laboratory is operating under the supervision of a qualified microbiologist or equivalent. To obtain the most accurate results, samples should be analyzed as soon after collection as possible. If samples must be transported to an off-site laboratory, they should be shipped to the laboratory under refrigeration on the same day they are collected, via an overnight delivery or courier service. Multiple samples collected on the same day can be shipped together to the laboratory in the sample shipping container and should be analyzed individually and not composited into one sample. To ensure sample integrity and an accurate bacterial count, a sample should arrive at the laboratory and the analysis initiated within 48 hours of collection. If the shipment and the initiation of the laboratory analysis cannot be accomplished within 48 hours of the sample collection, the carcass or product selected for sampling should be held under refrigeration and not sampled until the shipping and initiation of the sample analysis can be accomplished within 48 hours of sample collection. The same principle applies for samples that are analyzed in-plant: if the sample cannot be processed for testing within 48 hours of collection, the carcass selected for sampling should be held under refrigeration and sample collection delayed until the sample can be processed for testing within 48 hours of collection. FSIS recommends including the sample date and the date the laboratory started processing the sample to be included in the establishment records. Sponge or excised tissue samples should not be held for an extended period prior to analysis. They should be analyzed in-plant within 48 hours or shipped on the day of collection for overnight delivery to the laboratory that will conduct the analysis shortly after the sample arrives. Sponge or excised tissue samples should be held at refrigerated temperatures, not frozen, and shipped cold to the laboratory in an insulated shipping container with frozen gel packs. Lastly, the identity and security of all microbiological samples should be maintained during shipping and analysis to ensure the integrity of the test results.

Recordkeeping Under the final rule, swine slaughter establishments are required to maintain daily records sufficient to document the implementation and monitoring of the procedures to prevent fecal and microbiological contamination of product throughout the slaughter process. Records may be maintained on computers if the establishment implements appropriate controls to ensure the integrity of the electronic data. Records must be maintained for at least 1 year and must be accessible to FSIS upon request. To meet requirements, establishments need to maintain records sufficient to document the implementation and monitoring of sample collections; the testing procedures, including support for the adequacy of the testing frequency; and the test results. Records should include information, such as the: \u2022 Time, date, and location of the sample collection; \u2022 Sample collector's name; \u2022 Name or description of the product or sample source; and \u2022 Lot information and producer. All entries should be dated and initialed by the sample collector immediately upon completion of the entry. If an outside laboratory is used for testing, then these records should also include sample shipment information, including sample identification information, shipment date and time, courier or other delivery service used, and shipment tracking information. The outside laboratory should maintain chain of custody and document the: \u2022 Date the sample was received; \u2022 Condition of the sample upon receipt, including sample temperature, if applicable; \u2022 Date the analysis was started and completed; and the \u2022 Test result. Test results should also be recorded and linked to the sample collection records by a sample number, form number, or some other unique identifier.

These records should be maintained in a way that ensures the integrity of the data. As noted above, these records can be maintained in an electronic format, provided there are measures in place to ensure the integrity of the information. These records should be readily accessible for review by the establishment and FSIS inspection program personnel upon request. Using Statistical Process Control to Interpret Test Results from Carcass Sampling Statistical process control provides a powerful mechanism for establishments to assess and interpret the data collected for ongoing HACCP verification. Statistical process control can provide an establishment with an early warning that its process may not be functioning as designed. This warning can allow an establishment to take corrective actions or make other process modifications to bring its process back into control. Statistical process control can also provide an establishment with reasonable assurance that its HACCP system is functioning as designed.

15", "Establishments should consider available guidance and develop a statistically valid approach for interpreting sample results (Saini et al. 2011 and De Vries 2010). In cases where an establishment does not have the resources or capacity to develop its own statistical control limits or analytical procedures, establishments can utilize the results from the FSIS MHBS, provided in Table 2. The specific indicator organism limits for generic E. coli, APC, Enterobacteriaceae, and total coliforms correspond to the 80th percentile limit. FSIS compared the presence and levels of specific microbiological targets to determine whether significant differences existed between samples taken at pre-evisceration and post-chill. Percentiles represent the percent of establishments that are below the associated number in the distribution of average bacteria indicators per establishment. These indicator organism limits can be used by establishments to verify their process control. Given that samples collected per establishment in the FSIS MHBS were limited and the variation within individual establishments was high, the control limits in Table 2 are approximations. Charting and Interpreting Test Results for Carcass Sampling Specific techniques of statistical process control include the use of a control chart, which plots data over time but also displays an upper control limit for specific measurements and often a centerline, above and below which one would expect approximately an equal number of sample results, since the centerline is based on past sampling history. A sample result above the upper control limit would indicate the likely presence of a special cause of variation that should be addressed. Results within control limits indicate simply that the process is in control. Control charts are used to: A. Analyze and understand variables that affect the process; B. Determine process capabilities; and C. Assess effects of the variables on the difference between target and actual performance. Test results should be plotted and evaluated in a series over time. The test result chart should be updated at a regular interval, ideally within the next business day following the reporting of test results by the testing laboratory. Every time a new test result is recorded, the oldest test in the series should be dropped from the moving window. For example, an establishment may choose to evaluate its test results in a moving window of 13 tests. The establishment would use this series of 13 tests to evaluate its process control over the period represented by the series of 13 tests. The control chart would be updated with each new test result reported, adding the new test result and removing the oldest test result on the chart. Refer to Appendix 2 below for hypothetical examples of process control charts. 16", "Microbiological testing provides a measure of the extent of control at the step being evaluated and all preceding steps. By performing microbiological analyses at several points within a process it is relatively easy to identify the

segment of the process where control has been lost. In addition, sanitary dressing verification and end-product testing (though not required) can provide an integrated measure of the performance of the entire process. Pre-evisceration and post-chill test results could be charted on the same graph with separate, corresponding upper control limits to better correlate the samples and calculate the log reduction between the two samples. Actions in Response to Loss of Process Control As part of its process control procedures, an establishment should define the actions it will take if the test results obtained exceed the limits it has set. The establishment should delineate what its actions will be, who will take each action, how the outcome of these actions will be documented, and how the actions will be verified. FSIS has made available the Compliance Guideline for Controlling Salmonella in Market Hogs. The guideline summarizes potential control points for Salmonella in the pre-and post-harvest production process. Establishments should use this guide to improve management practices, to ensure effective sanitary dressing procedures and to assist in investigating events of apparent loss of process control. When an establishment makes changes at the appropriate locations in its process, process control should improve and result in the production of raw pork products that are within acceptable parameters, including indicator organisms and Salmonella. If an establishment determines that the trends in its test results indicate a loss of process control, the establishment should act to investigate the root cause(s). As discussed in the previous section on process control, an establishment should consider how the different parts of its food safety system work together and how they affect the entire food safety system. To do this, establishments should evaluate its process control procedures, sanitary dressing practices, and sanitation procedures to determine whether the root cause(s) can be identified, and subsequently, take steps to correct the problem. This evaluation should include a review of an establishment's process monitoring records and its processes during normal operations. The establishment should consider any implementation problems it has encountered or changes in procedures or practices, such as sanitary dressing procedures, including but not limited to: Procedures for routine cleaning and sanitizing of equipment, including hand tools used to remove contamination or to make cuts into the carcass; The design, configuration, and calibration of equipment to ensure proper function within operational parameters to prevent contact between carcasses and parts, and prevent contamination of carcasses; Employee hygiene practices, such as ensuring employees frequently wash hands, equipment, utensils, and aprons that come in contact with carcasses, and that employees are properly trained when there are new or substitute employees on the line; and The implementation of antimicrobial or mechanical intervention treatments, such as carcass washes, sprays, or brushes, in accordance with the limits selected and supported by the establishment, including effective application to ensure coverage of the entire carcass. Following its investigation, the establishment should respond to its findings by deploying appropriate decontamination procedures and antimicrobial intervention treatments, as necessary, to address contamination that may have occurred on carcasses or parts. The establishment should also take steps to initiate any necessary equipment repair or recalibration and employee training, when identified as a root cause for loss of process control.

Congressional Review Act 3 55", "I. PURPOSE This guideline can be used to assist swine	
slaughter establishments train their employees (hereafter referred to as sorters) to conduct the	
live animal and carcass sorting and trimming activities that are required for establishments that	
voluntarily adopt the New Swine Slaughter Inspection System (NSIS). II. BACKGROUND The	
Food Safety and Inspection Service (FSIS) has established a new voluntary inspection system for	
establishments that slaughter market hogs called the NSIS. Under the NSIS, establishments	
assume additional responsibilities for the sorting and removal of abnormal or unhealthy	
animals before FSIS ante-mortem inspection and adulterated carcasses and parts before FSIS	
post-mortem inspection. The Agency believes that training sorters in establishments that adopt	
NSIS is important to ensure that they are able to properly perform their sorting procedures	
before FSIS inspection. The content of this guideline is based on the same training that FSIS	
provides to its own inspection program personnel (IPP). The Agency is posting this guideline on	
the FSIS Web site at: <a href="http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatory-compliance/compliance-guidesindex">http://www.fsis.usda.gov/wps/portal/fsis/topics/regulatory-compliance/compliance-guidesindex</a> . This guideline explains how establishments can meet	
FSIS requirements regarding sorting activities under the NSIS and represents FSIS\u2019s	
current thinking on this topic. FSIS encourages establishments planning to operate under the	
NSIS to use this guideline when developing their own training for their sorters. A. Does NSIS	
change how inspection program personnel (IPP) perform ante-mortem inspection? No. FSIS IPP	
will continue to inspect 100% of all market hogs presented for ante-mortem inspection by the	
establishment after the establishment has conducted sorting activities. FSIS IPP will continue to	
verify humane handling of all market hogs on premises. The NSIS will not affect the regulations	
that prescribe animal disposition procedures. Per FSIS Directive 6100.1, the FSIS Public Health	
Veterinarian (PHV) continues to make one of the following dispositions for market hogs	
presented for inspection: 1. Passed for normal slaughter; 2. Passed for slaughter but tagged as a	
U.S. Suspect animal (9 CFR 309.18 (a)). In addition, swine slaughtered in a dehairing operation	

must also have a tattoo applied when identified as a U.S. Suspect animal (9 CFR 309.18 (b)); or 3. Condemned and tagged as a U.S. Condemned animal (9 CFR 309.18 (c)). B. Does NSIS change FSIS humane handling verification or requirements? 4", "No. FSIS IPP will continue to verify the humane handling of all animals on the premises, including market hogs on the establishment\u2019s premises that are not presented for inspection. NSIS provides the opportunity for IPP to perform more humane handling verification. For information on humane slaughter, please refer to the FSIS Compliance Guide for a Systematic Approach to the Humane Handling of Livestock available at:

<https://www.fsis.usda.gov/wps/wcm/connect/da6cb63d-5818-4999-84f1-72e6dabb9501/CompGuide-Systematic-Approach-Humane-Handling-Livestock.pdf?MOD=AJPERES>

C. Does NSIS change how FSIS performs post-mortem inspection? No, as with traditional inspection, FSIS continues to perform 100% carcass-by-carcass inspection on each head, viscera, and carcass. After establishment sorters on the line have identified any conditions for carcass or parts removal or trimming, FSIS inspects each head, viscera, and carcass to ensure that they are fit to bear the mark of inspection and that establishment\u2019s sorting decisions meet regulatory requirements. FSIS continues to have the authority to retain carcasses and stop the line under NSIS. FSIS also continues to conduct offline inspection activities such as verifying compliance with sanitation and Hazard Analysis and Critical Control Point (HACCP) regulations, as well as humane handling requirements.

It\u2019s important to note that NSIS does allow FSIS inspectors to conduct more off-line verification activities. D. Questions Regarding Topics in this Guideline FSIS recommends that users who have questions regarding the information covered in this guideline search the publicly posted Questions & Answers (Q&As) in the askFSIS database or submit questions through askFSIS. Documenting these questions helps FSIS improve and refine present and future versions of the guideline and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter NSIS Sorting Guideline. Question Field: Enter question with as much detail as possible.

Product Field: Select General Inspection Policy from the drop-down menu. Category Field: Select Slaughter from the drop-down menu. Policy Area: Select Domestic (U.S.) Only from the drop-down menu. When all fields are complete, press Continue. III. GUIDANCE FOR

ESTABLISHMENT EMPLOYEE SORTER TRAINING PROGRAMS A. Training Program Elements This guideline recommends training elements and inspection standards that the Agency has found effective in training FSIS inspectors to identify live animals, carcasses and parts affected with defects and condemnable conditions. Market hog establishments may use this information to train establishment employees who will conduct sorting activities under the NSIS. 5", "Proper training is important to establishment sorters\u2019 ability to make sorting decisions on animals, carcasses, and parts. Under the NSIS, FSIS inspectors will continue to inspect all carcasses and parts and take regulatory control actions, if necessary. If establishment sorters do not make correct sorting decisions, IPP will continue to retain carcasses and parts for veterinary disposition; stop the production line; identify and verify restoration of contaminated carcasses or parts; and issue non-compliance records (NRs). Under the NSIS, the PHV will continue to have the authority to direct the establishment to reduce its line speed to maintain process control and assure that the FSIS online carcass inspectors are able to conduct a carcass-by-carcass inspection. A single training method or program may not be applicable to all

establishments. Individual establishments should design training programs consistent with the operational conditions in their establishment. FSIS recommends that each establishment develop a standardized training program for its sorters to properly identify unfit live animals and unwholesome carcasses and parts to ensure that such live animals, carcasses, and parts are not used as human food. FSIS recommends that sorter training programs include the components and content listed below: Classroom training refers to lecture style presentations that provide essential information for sorters that will assist them to: \u2022 Recognize and name common parts of market hog carcasses and organs; \u2022 Recognize and name common conditions affecting market hog carcasses and viscera; \u2022 Differentiate among normal, localized, and generalized conditions affecting market hog carcasses and viscera; \u2022 Determine the appropriate actions to take to ensure removal and disposal of unwholesome and unfit carcasses, parts, or viscera to ensure they cannot be used as human food; and \u2022 Create records documenting establishment sorting. NOTE: An exam or self-assessment for establishment sorter trainees following classroom and hands-on (i.e. wet lab) training may be helpful to measure and quantify understanding and comprehension of training. Hands-on (i.e. Wet Lab) Training is an activity that provides trainees with practical application of what they learn during classroom training. Features could include: \u2022 Using real examples of carcasses and parts \u2013 both normal and abnormal; \u2022 Performing hands-on practice prior to beginning normal duties online to identify carcass and parts conditions; \u2022 Assuring carcass and parts sorting decisions are correct and \u2022 Recording sorting and removal actions. On-the-Job Training is practicing what has been learned in the classroom and through wet labs in an establishment to an environment that simulates an establishment including: \u2022 Performing sorting activities at production rates; \u2022 Identifying defects on carcass, parts, and viscera; \u2022 Receiving real time feedback from supervisors; and \u2022 Taking appropriate actions (e.g., trimming contamination and identifying defects for removal or disposal) as determined necessary. Follow-up Sessions (referred to as correlations) are conducted to reinforce previous learning. Features include: \u2022 Conducting such sessions at a set regular frequency, \u2022 Discussing regularly standardized procedures for identifying and properly disposing of carcasses and parts on a continuous basis at production rates; and \u2022 Describing reasons for making decisions during sorting activities and appropriate actions. Continuous Monitoring of individual employee performance to maintain skill level.

**IV. COMPONENTS OF AN EFFECTIVE ANTE-MORTEM SORTING PROGRAM**

**A. Pre-Sorting Prior to Arrival:**

1. Pre-sorting on the farm:
  - a. Establishment purchase specifications
  - b. Treatment records
  - c. Animal health
  - d. Biosecurity procedures
2. On farm certification programs:
  - a. Pork Quality Assurance Program (PQAP)
  - b. Common Swine Industry Audit
  - c. Truckers Quality Assurance Programs

Under the NSIS, FSIS encourages establishments to begin their sorting activities by collecting and utilizing previous slaughter data for each supplier, and producer information including, in part: farm records, feeding programs, herd certification programs, and farm biosecurity programs, to ensure only healthy market hogs are delivered to the establishment. Systematic use of rigorous on farm sorting procedures, purchase specifications, and herd certifications will further ensure that animals with chemical, physical and biological hazards, including chemical hazards from violative residues, are not delivered to the slaughter establishment. On farm programs may be used by the establishment to support, in the establishment\u2019s HACCP system, ante-mortem and post-mortem sorting

procedures.

B. Sorting on Premises: How to Implement an Effective Ante-Mortem Sorting Program

1. Be familiar with the behavior of normal healthy market hogs.
2. Observe market hogs in motion; specifically look for:
  - a. Alertness: Healthy market hogs are aware of their surroundings and actively investigate the environment and their pen mates when initially unloaded or placed in pens. During lairage, market hogs will be recumbent and resting for most of the time.
  - b. Locomotion: Healthy market hogs bear weight equally on all four legs and walk freely.
  - c. Body condition: Healthy market hogs are full fleshed, with fat and muscle completely covering the ribs, backbone and hips.
  - d. Body functions: Healthy market hogs pass clear to pale yellow urine and formed yellow to greenish to brown stools, depending upon their diet. Market hogs may vomit due to motion sickness, so occasional vomiting in an otherwise healthy market hog should not be cause for concern.
3. Observe market hogs at rest; specifically look for:
  - a. Alertness: Healthy market hogs retain awareness of what is going on around them when resting and often vocalize when disturbed.
  - b. Respiration: Healthy market hogs display regular, rhythmic breathing.
  - c. Skin color: Healthy market hogs will have a white to pink uniformly colored skin (if not pigmented).

C. Ante-Mortem Conditions Requiring Removal and Identification for Disposal

1. Dead.
2. Moribund: Animals in the act of dying. Look for inactivity, loss of awareness of surroundings, abnormal skin color (blotchy or blue discolorations), irregular (gasping) respirations, frothy mouth and / or nasal discharge, unable to rise and walk.
3. Central nervous system (CNS) diseases. Look for seizures, convulsions, abnormal gait (circling, dizziness, loss of balance), difficulty swallowing, abnormally excited or aggressive behavior, head pressing or head tilt.
4. Febrile. Market hogs with an elevated body temperature are febrile. Normal body temperature of a pig is around 101.5°F - 102.5°F. Pyrexia is a febrile state when their body temperature is 106.0 F or higher. Look for loss of activity and awareness, reddish or bluish skin discoloration in white hogs, increased respirations, difficulty breathing, reluctance to get up from a recumbent position, and / or lameness.

NOTE: Establishment sorters must notify FSIS if they observe animals exhibiting signs of CNS diseases because these are reportable diseases. Establishment sorters must also notify FSIS if they observe an abnormal change in the amount of dead, moribund, or febrile animals because these could be signs of a reportable or foreign animal disease.

D. Ante-Mortem Conditions Requiring Sorting of Swine with Other Conditions; Holding Market Hogs in the \u201cSubject\u201d Pen; Further Sorting by the Establishment Lead Sorter; and Final Inspection by the FSIS PHV:

1. Fatigued or non-ambulatory market hogs. Fatigued market hogs appear normal at first but tire and become recumbent. Some fatigued market hogs suffer from muscle cramps and will vocalize and shake until they lay down. If isolated and allowed to rest, recovered fatigued market hogs are eligible for slaughter pending final sorting and FSIS inspection. If any market hogs become non-ambulatory disabled after ante-mortem inspection, establishments are required to move them to the \u201cSubject\u201d pens for reinspection by FSIS PHVs.
2. Overheated market hogs. Market hogs do not control their body temperatures well during warm weather and may overheat during inclement weather. Look for rapid, panting respirations, reddish skin discoloration, and lack of activity. These animals may be held for recovery and passing for slaughter, pending further sorting and final PHV inspection.

8", "3. Market hogs of uncertain status at the time of initial sorting. If establishment sorters are unsure about the health status of a market hog or its eligibility for production into human food, they should place the pigs in a pen that will be subject to further sorting by the

establishment's lead sorter (i.e., the establishment's designated offline sorter), and final inspection by the FSIS PHV. Conditions that sorters may question include abnormal body swellings, lameness, skin discolorations, scabs, wounds, coughing, sneezing, and abnormal body discharges (bloody urine, diarrhea, vaginal discharges, vomiting). Examples of Ante-Mortem Conditions Arthritis Signs: 1. Enlargement of one or more joints; 2. Abnormal locomotion; 3. Variable temperature depending upon stage of disease and ambient temperature. Temperature may range from very high to subnormal; each case will have to be independently assessed by the PHV; 4. Painful or abnormal stance and movement; 5. Reluctance to move or stand; 6. Depression; 7. Poor wasting condition; and/or 8. Infected navel in young animals. Special Note: Transport injury (i.e., sore feet) this also can result from market hogs being raised on concrete and must be distinguished from arthritis (See 9 CFR 309.2, 309.4, and 309.9). 9", "Moribund-Dying Condition Market hogs showing darkening of the abdomen or cyanosis of the belly and ears (see picture to the left); very depressed -typical of market hogs in a moribund or dying condition: Signs include: Depression, Reluctance to move, Cold dark ears, legs, belly, Reduced or elevated body temperature, Inability to rise, Paddling, Unaware of surroundings, Moribund, and Dehydration. Acute Erysipelas Signs: Fever; Reluctant to move; nonambulatory; Swollen joints; Sudden death; and/or Diffuse areas of purple raised, red diamond skin. Sorters must identify animals with signs of fever and signs of acute erysipelas for disposal. Market hogs with less severe signs suggesting a localized condition can move to the subject pen for closer evaluation and sorting. Eligible market hogs may be presented to the PHV for antemortem inspection. 10", "Abscess Signs: Swellings may be evident in various parts of the animal; Typically, abscesses of any size may be seen near the jowl, ham, hock, shoulder. Abscess/Hernia/Prolapse/Injury Depression or lethargy; Variable temperature from very high to subnormal; External wounds including Scirrhous cord (funiculitis), Umbilical abscess, tail-bite lesions, or infected open wounds; Swollen joints; Subcutaneous abscesses; and/or Poor wasting condition. E. Summary: Outcomes of Sorting 1. Normal healthy market hogs presented for FSIS ante-mortem inspection. 2. Market hogs identified for removal are humanely euthanized (if necessary), denatured, and disposed of. 3. Plant rejects (healthy animals that may be underweight, overweight, or do not meet other establishment purchase specifications) that are moved to another inspected establishment for slaughter only. 4. Market hogs that are held for further sorting in the Subject pen by establishment lead sorter and final inspection by the PHV. F. Foreign Animal Diseases (FADs) FSIS has a cooperative agreement with the Animal and Plant Health Inspection Service (APHIS) for conducting FAD surveillance during FSIS inspections. FADs of concern include Foot-and-Mouth Disease (FMD) (see picture on page 42), Hog Cholera, and African Swine Fever. As part of the NSIS, establishments are required to report any animal showing a condition suggestive of a FAD or other reportable conditions to the FSIS PHV (9 CFR 309.19(e)). The FSIS PHV will inspect for and make the final determination about whether the condition should be reported to APHIS. Early detection of FADs can help prevent spread of such diseases. Conditions associated with FADs and other reportable conditions include: 1. Sudden, unexplained death loss in a large number of market hogs upon arrival or that were previously observed as healthy; 2. Sudden, unexplained fever in a large number of market hogs; 3. Sudden, unexplained severe lameness in a large number of market hogs; 4. Vesicles (i.e. intact, ruptured, healing blisters or sores) on the nose and in between the toes; 5. Large numbers of market hogs with diarrhea; 6. Signs of

central nervous system disease (e.g. circling, head pressing, head tilt, staggering, tremors); and\or 7. Maggot infestations. Additional information about FADs and other reportable conditions may be found on the APHIS website at :<https://www.aphis.usda.gov/aphis/ourfocus/animalhealth/animaldisease-information> or by calling the APHIS Area Veterinarian In Charge:  
[https://www.aphis.usda.gov/vs/nahss/swine/csf/CSF\\_PM\\_2007\\_AppendC\\_Directory.pdf](https://www.aphis.usda.gov/vs/nahss/swine/csf/CSF_PM_2007_AppendC_Directory.pdf)

G. Establishment Recordkeeping of Disposed Carcasses Sorted Before Ante-Mortem or Slaughter Under the NSIS, establishments are required to keep: 1. Records documenting the number of animals that were sorted and removed for disposal before ante-mortem inspection or slaughter. Establishments do not need to include the number of healthy animals that were diverted to another official establishment for slaughter. Establishment records must include reasons the animals or carcasses were removed. This information must be provided to FSIS to fulfill FSIS reporting obligations. 2. Records documenting sorting activities and disposal procedures. These records will vary depending upon how the establishment conducts its sorting activities and disposes of animals and carcasses (HACCP, Sanitation Standard Operating Procedures (Sanitation SOPs), or other pre-requisite programs) within its HACCP system.

H. Denaturing Requirements The NSIS requires establishments to have written procedures documenting that all dead and discarded market hogs are identified (using a tag, tattoo or other unique identification) and disposed of according to 9 CFR part 314 (9 CFR 309.19). Establishments have the option to render on-site or denature carcasses before disposed carcasses are transported offsite. Establishments can also continue to use denaturing by injection to help identify carcasses rendered on site. If rendered offsite, discarded carcasses are to be denatured with: (1) crude carbolic acid, (2) cresylic disinfectant; (3) a formula consisting of one part FD&C No. 3 green coloring, 40 parts water, 40 parts liquid detergent, and 40 parts oil of citronella; or (4) any other proprietary material approved by the Administrator in specific cases, during hours of operation and before transport from the establishment. When such carcasses are dressed (e.g. skinned), the carcass is to be denatured; carcasses that are dressed are required to be freely slashed before the denaturing agent is applied, except that, in the case of dead animals that have not been dressed, the denaturant may be applied by injection. The denaturant must be deposited in all portions of the carcass to the extent necessary to preclude the carcass from being used for food purposes.

12", "V. COMPONENTS OF AN EFFECTIVE POST-MORTEM SORTING PROGRAM

A. Preparation and Proper Presentation of Carcasses and Parts

Before FSIS inspection, establishment employees can remove surface contamination (e.g., feces, ingesta, or milk) on market hog carcasses in a sanitary manner, unless the carcasses are retained by IPP for PHV inspection. Trimming of carcass defects or blemishes (e.g., hair and minor bruises) is allowed for any defects not affecting disposition of the carcass or part. To operate at maximum efficiency, FSIS recommends that establishment employees present heads, viscera, and carcasses in a consistent and uniform manner to allow sorters to methodically examine and sort heads, viscera, or carcasses prior to FSIS inspection.

NOTE: Sorting of hearts and kidneys requires the opening or removal of the pericardial membrane and kidney capsule. Kidneys may be presented with the viscera or in the carcass.

B. Normal Carcass and Parts Photos

Establishment personnel should be familiar with normal market hog carcasses and parts.

Normal Head 13", "Normal lungs, aorta, and lymph nodes. Healthy hearts; slashed and washed. Healthy liver, gall bladder, stomach; spleen and intestines. 14", "Healthy viscera.

Healthy mesenteric lymph node chain draining the intestines. 15", "Carcass tracking system. Carcass tracking system: Carcass Number; Time; and\or Tattoo. 16", "LARGE INTESTINE CECUM SMALL INTESTINE RECTUM OR BUNG 7. SWINE VISCERA GALL BLADDER STOMACH DIAPHRAGM WEASAND LIVER HEART TRACHEA LUNGS 17", ". SWINE CARCASS -INSIDE HOCK JOINT (HIND LEG) STIFLE JOINT AITCH BONE PELVIC CANAL ABDOMINAL CAVITY -LINED WITH PERITONEUM Hilc:--l-+~:+-1:-----KIDNEY -POPPED OUT OF CAPSULE (MEMBRANE AND FAT) DIAPHRAGM (PILLARS BY KIDNEY) THORACIC CAVITY (LINED WITH PLEURA) KNEE (FRONT LEG) STERNUM (BREASTBONE) ..L.....JOWL CUT SURFACE OF SPINAL COLUMN (BACKBONE) 6 18", "Normal Healthy Market Hog Carcass (Left) Pre-evisceration carcass with head attached. (Right) Post evisceration carcass after removal of head and splitting of the carcass and kidneys exposed. 19", "Healthy market hog carcass showing pelvic canal, lower abdominal wall, leaf lard, and iliac lymph nodes. Healthy kidneys in split carcass with capsule removed. Thoracic inlet of healthy market hog split carcass showing ribs, vertebrae, sternum, and lymph nodes. 20", "VI. MAINTAINING IDENTITY OF CARCASSES AND PARTS A. Carcasses and Parts Intended for Food The establishment must maintain identity of the carcass and associated head and viscera until the carcass, head, and viscera receive final inspection by FSIS (9 CFR 310.2). The establishment must also continue to demonstrate that they are able to retrieve the associated head and viscera of any carcass up until the point of final carcass inspection, should the carcass be retained by IPP for PHV disposition (9 CFR 310.3). B. Carcasses and Parts Intended for Disposal (Not Food) Before FSIS post-mortem inspection, establishment sorters are required to identify carcasses and parts intended for disposal (9 CFR 310.26). Once carcasses or parts identified for disposal have been inspected by FSIS, the establishment is required to initiate steps to denature them as inedible (unless designated as naturally inedible (e.g., hides with hair, claws, etc.) or render them (see 9 CFR parts 325 and 314). Collection of inedible parts in suitably marked containers for animal food must comply with denaturing or other permitted identification procedures under 9 CFR parts 325 and 416. VII. SORTING FOOD SAFETY CONDITIONS AT SLAUGHTER Establishment sorters must identify, sort, and mark for disposal market hog carcasses and all associated parts with the following food safety conditions (9 CFR 310.26): 1. Septicemia, 2. Toxemia, 3. Pyemia, 4. Cysticercosis, 5. Feces, 6. Ingesta, and 7. Milk Contamination. A. Septicemia Septicemia is a food safety condition caused by the presence of pathogenic microorganisms spread through the entire carcass by way of blood or lymphatics (see 9 CFR 311.16). Not all signs listed below will be present in every animal with septicemia. Post-Mortem Signs: 1. Dark and blood filled (i.e., congestion) organs or organs with infected wounds or dark bruises; 2. Pinpoint to blotchy hemorrhages (most noticeable on kidneys, heart, lungs, spleen, and other internal organ membrane (i.e., serous) surfaces, typically 0.125 to 1.0201d or greater in dimension). 21", "3. Generalized lymphadenitis (multiple, congested, inflamed, or enlarged lymph nodes): lymph nodes tend to be less inflamed but more enlarged 1-2 weeks after infection develops. Multiple lymph nodes are enlarged and cut surface of lymph nodes may be reddened or pale with a rough surface; 4. Pale degeneration of tissues or organs; 5. thin, pale (anemic); organs are pale in color; 6. Blood fails to clot; 7. Yellow to bloody fluid in abdominal and\or thoracic cavities; 7. Injection sites (recent); 8. Edema or other evidence of acute generalized inflammation; and\or 9. Hemorrhages under the skin, organs, and body surfaces. Disposal: Sorters must identify carcasses showing signs of septicemia for disposal under FSIS inspection. Special Notes: (1) Generalized, acute lymphadenitis (hemorrhage and

early enlargement of lymph nodes) alone is enough for discarding a carcass for septicemia. (2) A carcass manifesting any degree or form of septicemia is never passed by FSIS. (3) Petechial ((i.e., pinpoint, less than 1 mm in size) hemorrhages on a normal kidney alone in a healthy carcass are not conclusive evidence of septicemia. Carcasses with true septicemia will show signs in multiple areas or systems. Hemorrhagic lymph node associated with septicemia; generalized lymphadenopathy may be hemorrhagic or enlarged or both. 22", "Carcass showing signs of septicemia involving multiple organs; note hemorrhages and swelling of membranes covering heart, and organs themselves. Swollen enlarged kidney with petechial and larger ecchymotic (i.e. patches 5-15 mm in size) hemorrhages and scars compatible with a septicemia.

B. Toxemia Related to septicemia, toxemia (i.e., toxins in the blood) is a food safety condition caused by the circulation of toxins produced by pathogenic microorganisms or resulting from the death of microorganisms or tissues by way of the blood or lymphatics (see 9 CFR 311.16 and 311.17). Not all signs listed below will be present in every animal with toxemia.

Post-Mortem Signs:

1. Petechial or ecchymotic hemorrhages. These hemorrhages are most noticeable in kidneys, epicardium, lungs, and serous surfaces;
2. Generalized, acute lymphadenitis;
3. Pale enlarged organs;
4. Large or shrunken spleen;
5. Pale degeneration of tissues or organs;
6. Pigmentation of fat;

23", "7. Slight icterus and\or anemia; 8. Presence of areas of tissue necrosis, red-brown to yellow color to tissues and organs and fat; and\or 9. Changes associated with decomposing tissue (e.g., splenic torsion, liver or lung necrosis, or dead autolyzing fetus.)

Disposal: Sorters must identify carcasses showing signs of toxemia for disposal under FSIS inspection.

Special Notes: Signs of toxemia can appear in varying degrees in carcasses with septicemia. Septicemia, toxemia, or both may simultaneously occur in cases of diseases like septic mastitis, metritis, or arthritis.

C. Pyemia Pyemia (i.e., pus forming bacteria in the blood) is a food safety condition. Pus forming bacteria from wounds or injuries enter the bloodstream and form abscesses in the lungs, joints, or throughout the body (see 9 CFR 311.16 and 311.17).

Post-Mortem Signs:

1. Infected wound;
2. Swollen joint or joints;
3. Multiple abscesses in lungs with changes in visceral organs;
4. Hemorrhages in lungs, and visceral organs;
5. small abscesses (i.e., 1mm in size) in lungs are recent and do not have capsules;

Degeneration of tissues or organs with multiple small abscesses in lungs; and\or 6. Multiple enlarged, inflamed, or swollen lymph nodes.

Disposal: Sorters must identify carcasses showing signs of pyemia for disposal under FSIS inspection.

Special Notes:

- (1) Neoplasia may appear as a large abscess with a thick capsule seen with old localized abscesses.
- (2) Tuberculosis (TB) may appear as a purulent gritty abscess in certain situations.
- (3) Although a pyemia may have caused them, multiple, localized, encapsulated abscesses throughout the body should not be confused with an active pyemia.

24", "25 Micro-abscesses in heart, joint; spleen, and kidney suggesting a pyemia.

D. Cysticercosis of Swine (Pork Measles) Cysticercosis (pork measles) is a public health concern because it is a parasitic condition transmissible to humans (see 9 CFR 311.24). Cysticercosis cysts are the larval form (i.e., cysts) of the tapeworm *Taenia soleum*. Cysticercosis is very rare in domestic market hogs raised under modern and hygienic animal production methods but could reappear at any time, depending on the supplier. Cysticercosis is a rare but reportable disease (i.e., requires notification to FSIS). Cysticercosis should be considered any time multiple small cysts are observed in large muscle cuts, heart, diaphragm, or weasand.

Post-Mortem Signs:

1. Muscle is edematous or discolored;
2. One to several dozen cysts in muscle of heart, tongue, esophagus (i.e., weasand), or carcass;
3. Grape-like clusters in

tissue underneath the tongue or attached to heart; and\or 4. Cysts may occasionally be found in fat and viscera. Disposal: Sorters must identify carcasses showing signs of cysticercosis for either disposal or further inspection by FSIS PHV (if going to cooking)(see 9 CFR 315.2). FSIS recommends that the lead establishment sorter contact the FSIS PHV for assistance whenever cysts are observed in any organ or muscles.", "Pork Measles (Cysticercosis) -Cysts in Muscle. Heart muscle showing live cysts. E. Contamination with Feces, Ingesta, or Milk Refer to descriptions in FSIS Directive 6420.2. VIII. OTHER CONDITIONS REQUIRING SORTING This section provides guidance relative to the most common abnormal conditions seen in market hogs that are not directly associated with food safety but require sorting, trimming, or disposal depending on the nature, degree, or extent of the condition. A. Abscess Abscesses in the lymph nodes must be differentiated from granulomas (e.g. TB) and tumors (e.g. malignant lymphomas) (see 9 CFR 311.14). Abscesses in the neck or jowl may originate from old injection sites. Abscesses in the spine may originate from previously infected tail-bite wounds. Abscesses in swine soft tissues typically have a thick wall surrounding a yellow creamy pus-filled center. Pus can be pinkish to white in color, depending on the agent. Abscesses may be found anywhere on the carcass, joint, bone, or visceral organ. Large abscesses in the lung are often the result of the body walling off a lung lobe destroyed by 26", "pneumonia. Multiple localized abscesses that are well encapsulated within the main limb joints (or ends of long bones) are not indicative of pyemia, unless there is the simultaneous appearance of small abscesses and systemic changes in organs (e.g. lungs, spleen, kidneys and liver) due to an active spread of pyogenic microorganisms in the blood. Post-mortem signs: 1. Abscesses in various parts of the carcass or organs; 2. Abscess capsules may be thin (active; recent) or thick (more chronic). Pus may have any texture and color is mostly yellow, rarely red-brown, greenish-white to white in color; 3. Enlarged lymph nodes identified as localized, acute or chronic, reactive, or edematous lymphadenitis draining the affected area. Disposal: Heads: Sorters are required to identify localized abscesses and associated lymph nodes for removal under FSIS inspection. Carcass: Sorters are required to identify localized abscesses for removal under FSIS inspection. Carcasses affected with multiple abscesses affecting the entire carcass are required to be identified for disposal under FSIS inspection. Special Notes: Proper disposition of the carcass is improved when findings of abscesses or TB in the head are marked on the carcass and visible to viscera sorters. Abscesses may be mistaken for other conditions including those listed below. (1)True abscesses in the head or jowl can be differentiated from other conditions by the presence of visible scar tissue surrounding the abscess or lymph node. An abscess in the head may extend to the jowl. Head sorters should look for contamination from abscesses in neck and identified for disposal under inspection. (2) Large old tumors may have a necrotic center. Old lymphomas in the head or neck may have a dry yellow center up to 1\u201d in diameter that may appear as an old chronic abscess. (3)Fungal granulomas and classic TB may appear as a thick or grainy (calcified) abscess of 13mm in size. Establishments are encouraged to review any carcass or thoracic granulomas found with the PHV (if not retained by FSIS IPP.). B. Arthritis Arthritis is the inflammation of joint tissues that may be traumatic (as evidenced by blood joint fluid) or infectious in origin (see 9 CFR 311.7). Post-Mortem Signs: 1. Enlarged joint; 2", "2. Reactive or congested regional lymph nodes that drain the affected joint; 3. Degeneration of tissues or organs; 4. Septic wounds or other infections may spread to the joints causing arthritis; 5. Proliferation of the joint lining occurs as the joint heals; 6. Character of exudate in joints: a.

Increased amount of joint fluid, b. Clear blood-tinged joint fluid (injury), c. Cloudy red to yellow orange joint fluid (inflammation, infection). Disposal: Sorters are required to identify localized arthritis for removal under FSIS inspection. Sorters are required to identify carcasses showing signs of acute, systemic, or generalized arthritis for disposal under FSIS inspection. Special Notes: (1)Normal joints have a small amount of clear viscous joint fluid. Increased amount of joint fluid is often associated with injury, such as being confined on concrete or being hauled long distances to market. Often this fluid is clear but may show signs of fresh blood when associated with trauma. Fresh watery bloody joint fluid without evidence of cloudy, fibrinous or purulent exudate would be more indicative of trauma than infection. (2)As far as carcass disposal is concerned, the type of exudate present in the joints is not the primary consideration, whether the condition is generalized (systemic) is of most public health importance. (3)Opening arthritic joints may result in contamination of the carcass and if not avoidable, requires removal under FSIS inspection. (4)The tarsal (hock) joints of market hog carcasses affected with localized arthritis may be removed on the pork cut if the joint is bone solid without evidence of pus or tracks. (5) Establishments dispose of carcasses because of the condition of the joints, not the number of affected joints. If the arthritis is localized and can be removed by trimming, the joint should be disposed of under FSIS inspection and removed with any draining lymph nodes, and the carcass passed for food. (6) Establishments should not open arthritic joints on carcasses to avoid inevitable contamination of edible product with joint exudate. 28", "29 C. Pericarditis Pericarditis is an inflammatory condition of the heart sac (pericardium) that is usually due to an infectious agent (see 9 CFR 311.16). Post-Mortem Signs: 1. Adhesions of pericardium and pleura covering ribs or lungs \u2013 normal to inflamed red in color; 2. Sero-fibrinous or fibrinous pericarditis or epicarditis (shaggy heart); Inflammation of Hock Bone or Joint-abscess or arthritis likely; pyemia possible. Normal heart next to an enlarged heart with a mild inflamed heart surface with epicarditis or pericarditis (multiple surfaces).", "3. Edema of body tissues and fluid accumulations (ascites, pleural effusion); and 4. Putrefactive odor of cut-surface of pericardial, abdominal, or thoracic lesion. Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses with reddened (inflamed) or bloody pus on heart sac associated with multiple other carcass changes for disposal under FSIS inspection. Special Notes: Inflammation of the heart valve(s) is \u201cdocarditis\u201d and may be associated with septicemia, pyemia, or previous pneumonia. D. Pleuritis Pleuritis is an inflammatory condition of the pleural (lung and ribs) lining due primarily to infectious agents. It is often associated with pleuritis (see 9 CFR 311.16). Notice normal and inflamed lungs attached to ribcage. Post-Mortem Signs: 1. Adhesions between lungs, heart and ribs; 2. Fluid in the chest cavity; and\or 3. Reddened to enlarged lymph nodes within the chest. Disposal: Sorters are required to identify carcasses with chronic, localized (i.e. healed) adhesions on the rib cage for removal under FSIS inspection. Sorters are required to identify carcasses showing the following signs of acute, systemic, or generalized pleuritis for disposal under FSIS inspection: 1. Extensive, reddened lungs and surface of the ribs; or 2. Reactive or congested (reddened) lymph nodes draining lungs; heart, and ribs and body. Special Notes: Pleuritis can be associated with pneumonia or be a separate disease. E. Pneumonia 30", "Pneumonia is an inflammatory condition of the lungs that may be caused by infectious agents, parasites, physical trauma, or foreign material inhalation (see 9 CFR 311.16). Pulmonary hemorrhage, edema -Check for signs of septicemia. Post-Mortem Signs: 1. Lungs

may be reddened to grayish in color; 2. Lymph nodes draining lungs may be swollen, hemorrhagic, or enlarged; 3. Changes in color, size, or shape of liver, spleen, and kidneys; 4. Hemorrhages (spots) on lungs, kidneys, viscera, or carcass; 5. Consolidation of lung lobe into a thick-walled abscess; and\or 6. Parasites. Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses showing the following signs of acute, systemic, or generalized pneumonia for disposal: 1. Heavy, red, inflamed lungs with reactive inflamed lymph nodes; 2. Red, inflamed adhesions on ribs; 3. Changes in color, size, shape of kidneys, spleen, or viscera; 4. Pale or anemic carcass; and\or 5. Marked pulmonary necrosis (abscess) with associated toxemic changes. F. Peritonitis 31", "Peritonitis is a common condition marked by inflammatory processes affecting the peritoneal lining that is usually caused by infectious agents; however, it can be initiated by intraperitoneal medications, ruptured bladder, or other irritants (see 9 CFR 311.16). Notice the discoloration of the leaf lard suggesting a peritonitis. Here is an inflamed and distended loop of intestine with congested mesenteric lymph nodes from a carcass that may have an associated peritonitis. Post-Mortem Signs: 1. Gastroenteritis -pathologic hemorrhage in stomach, intestines, abdominal organs, or walls; 2. Generalized, acute lymphadenitis; 32", "3. Degeneration of tissues or organs; and 4. Accumulation of fluid in abdominal cavity. Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses with the following signs of acute, systemic, or generalized peritonitis for disposal: 1. Acute diffuse peritonitis without generalized changes; or 2. Peritonitis associated with generalized changes. G. Gastroenteritis Gastroenteritis is inflammation of stomach or intestine (see 9 CFR 311.16). Notice the enlarged, darkened, blood filled loops of intestine and enlarged darkened spleen. Post-Mortem Signs: 1. Inflammation of stomach or intestine and draining lymph nodes; 2. Dark, blood-filled intestinal loops; 3. Gangrenous stomach or intestine; 33", "4. Intestinal emphysema (foamy intestines); and\or 5. Thickened \u201cgarden-hose\u201d intestine. Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses showing the following signs of acute, systemic, or generalized gastroenteritis for disposal under FSIS inspection: 1. Acute, extensive hemorrhagic or gangrenous enteritis; or 2. Any degree of gastroenteritis with generalized (systemic) changes. Special Notes: FSIS recommends that sorters notify the PHV when multiple carcasses from the same lot show signs of gastroenteritis because this could be a sign of a reportable animal disease. H. Nephritis Nephritis is an inflammatory condition of the kidneys (see 9 CFR 311.16). Proper presentation of the kidney for sorting and inspection requires removal of the kidney capsule. There are several types of conditions in kidneys that warrant disposal and closer examination of the carcass. Etiologies may include infectious agents, parasites, or toxins. Notice the raised pale plaques on the surface of the swollen edematous kidney. Notice the striations that run from the center to the outer cortex of the kidney. Kidneys have white spots raised or flattened and show up as white streaks on cut surface. To differentiate from lymphoma, look for evidence of lymphoma in other tissues. Laboratory assistance may be required. Establishments may review kidney dispositions with the PHV if they have questions. 34", "35 Acute interstitial nephritis \u2013 a type of inflammation of the kidneys from bacteria in blood or urinary tract. FSIS recommends that establishment sorters check for evidence of septicemia in the carcass. Notice the pale enlarged kidneys with hemorrhages on the surface. Look for changes in lymph nodes and other

organs in the carcass. Chronic interstitial nephritis \u2013 Look for anemia or uremia in carcass Carcasses with chronic interstitial nephritis\u2014white, firm, depressed, or pitted or scarred kidneys\u2014may be presented to an FSIS PHV, who will determine if the carcasses can be passed for food, if there are no generalized changes (anemia; uremia), after condemnation of and removal of abnormal tissues.", "Pyelonephritis \u2013 Chronic inflammation of the ureter and kidney. The kidney appears virtually destroyed; FSIS recommends that establishment sorters also check the carcass for odors or anemia. Benign Embryonal Nephroma -a congenital kidney tumor. Congenital kidney tumor in swine (i.e. embryonal nephroma). Establishment sorters are required to identify the defect for removal under FSIS inspection. 36", "Carcass with Cystic Kidneys and Normal Kidney Tissue Hydronephrosis. Cystic Kidneys -one or both kidneys literally appear as a \"bag of water\". Normal kidney tissue is replaced by a large fluid cyst. There is generally no effect upon the carcass. Affected kidneys are typically removed and disposed of. Post-Mortem Signs: 1. Inflammation, enlargement, pathological hemorrhage, or change of color in kidney; 2. Multiple abscesses of entire kidney; 3. Pyelonephritis-- accumulation of pus in the ureters and into the kidney; 4. Degeneration of tissues, organs, and lymph nodes; 5. Carcass and tissue edema from protein loss in blood; and\|or 6. Uremic odor of carcass, indicating uremia. Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are to identify carcasses with the following signs of acute, systemic, or generalized nephritis for disposal under FSIS inspection: 1.Nephritis (acute or chronic) associated with generalized lesions or disease; 2.Pyelonephritis (dilated ureter and kidney) associated with generalized changes; or 3.Uremia associated with any stage or type of nephritis. Special Notes: Certain conditions should not be confused with primary nephritis including: (1)Kidney worms; (2)Urinary obstructions (kidney or bladder stones); (3) Infarcts; (4)Neoplasms (See embryonal nephromas and malignant lymphomas); (5)Cystic water filled kidneys; (7)Traumatic injuries; or (8)Depressed white areas\u2014scars resulting from previous infarcts or nephritis. I. Uremia 37", "Uremia literally means urine in the blood (see 9 CFR 311.16 and 311.37). Uremia may occur when the kidneys acutely fail to remove nitrogen (ammonia) waste materials in the blood. This can occur after kidneys are temporarily or permanently damaged or after total destruction of the kidneys. This can occur rapidly or over time. Post-Mortem Signs: 1. Hydrothorax; 2. Ascites or edema in the abdominal cavity; 3. Fluid in all body tissues with lack of inflammatory process; 4. Nephritis or pyelonephritis; 5. Peritonitis; 6. Cystitis; 7. Kidney stones; 8. Hydronephrosis; 9. Carcass edema and reddening; 10.Uremic odor to muscles; and\|or 11.Ruptured urinary bladder with peritonitis. Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses showing signs of uremia associated with nephritis for disposal under FSIS inspection. Special Notes: (1)If there is evidence of a localized urine odor in tissues, establishments are required to trim the affected area. (2)It is possible that a ruptured bladder can result from faulty dressing procedures. Such contaminated areas are required to be thoroughly trimmed. J. Tuberculosis (TB) Swine TB is an increasingly rare condition associated with the ingestion of pathogenic acid-fast organisms, almost exclusively identified as *Mycobacterium avium* (see 9 CFR 311.2). *M. avium* is known to be ubiquitous in the environment. The most recent infections have been historically associated with exposure to organic bedding, contaminated feed, and birds. FSIS slaughter data have shown the prevalence of *M. avium* in market hogs has steadily decreased. It is believed this decrease can be attributed to improved biosecurity methods

associated with modern production practices and raising market hogs indoors. Establishment management, sorters, and IPP cannot make the same assumptions when market hogs are raised outdoors or under other circumstances (e.g., free range). Sorters should be aware that TB lesions are most likely to be found in one or more parts of the carcass referred to as the \u201cprimary seats\u201d. The primary seats of TB lesions in the market hog carcass are the mandibular (jaw), the mesenteric (intestines), and the bronchial (airway) lymph nodes. TB lesions (e.g. granulomas) in swine have historically been identified through the incision of the mandibular lymph nodes and palpation of mesenteric, portal, and bronchial lymph nodes. Post-Mortem Signs: 38", "1. Increasingly rare, TB granulomas typically appear in incised lymph nodes as small grains of sand or small abscesses 0.5-2 mm in diameter. 2. When found in the mesenteric lymph nodes, they may appear as small abscesses just below the surface of the mesentery along the mesenteric lymph node chain. Disposal: Sorters are required to identify heads with TB lesions in mandibular lymph nodes for disposal under FSIS inspection. Viscera sorters must then perform closer examinations of the mesenteric lymph nodes for evidence of TB. If lesions are found in the mesenteric lymph nodes, the sorters should identify the carcass and viscera for closer examination by the lead sorter. Carcasses with generalized TB lesions, as demonstrated with lesions in 3 primary seats or outside of the primary seats (e.g., in muscle, joint, or organ), are to be disposed of under FSIS inspection. If lesions are located in two or more primary seats, the carcass and viscera must be held by sorters for further sorting by the establishment\u2019s lead sorter. Sorters also may request that the FSIS PHV inspect a carcass to determine if it may be passed for cooking (i.e., Passed for Cooking only). A lymph node showing multiple diffuse TB lesions. K. Parasites Not Transmissible to Humans 1. Stephanuriasis (Swine Kidney Worms) Stephanuriasis is a rare parasitic condition caused by the presence of Stephanurus dentatus in carcass tissues (see 9 CFR 311.25). This condition is most likely seen in swine raised outdoors in the South Atlantic and South-Central parts of the United States. This parasite is not known to be transmissible to humans. 39", "Kidney Worms. Post-Mortem Signs: 1. Adult kidney worms; 2. Lesions can include: a. Pelvic inlet, pelvic and femoral canal, b. Abdominal lining, c. Muscle-primarily loin and ham muscles, d. Organs-primarily kidney, liver, pancreas, spleen, and lungs, and\or e. Brownish-lemon color of skin and fat. Disposal: Sorters are required to identify carcasses for disposal when a parasitic infestation is associated with generalized disease, such as uremia or septicemia. Carcasses with numerous or extensive lesions also must be identified for disposal. Sorters are required to identify moderate infestations for removal under FSIS inspection. Or, sorters may request that the PHV inspect the product to determine if it may be passed for cooking. Special Notes: (1)The larvae of Stephanurus dentatus migrate to tissues surrounding the kidneys, form cysts and abscesses, and develop to adulthood. The area around the kidneys often appears reddish-brown, and the cysts contain a creamy to reddish-brown colored substance. It is even possible to palpate cord-like masses in the kidney fat, which are tracts made during migration. (2)In the liver, there are sometimes multiple extensive orange-tan hemorrhagic areas, with the liver parenchyma later taking on a mahogany color. Usually abscessation occurs where the larvae have been trapped. In addition, severe scarring results where abscessation has occurred. 2. Ascarids (Roundworms) Adult roundworms, Ascaris suum, may be observed in the intestines, bile ducts, and gall bladders of market hogs (see 9 CFR 311.25). Larval migration of ascarids causes \u201cmilk spots\u201d on pork livers and damage to lungs. \"Slight\" scarring may be trimmed (spotting

the liver). Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters may request that the PHV inspect the product to determine if it may be passed for cooking. Sorters are required to identify affected intestines with infestations of roundworms for disposal under FSIS inspection. 40", "L. Miscellaneous Skin Conditions; Vesicular Diseases Skin conditions are varied and many are very nonspecific, including conditions such as dermatitis, insect bites, erythema, urticaria, and photosensitization (see 9 CFR 311.21). Vesicles (blisters) on the head, snout, mouth, feet may indicate the presence of a reportable or FAD and must be reported to FSIS. Post-Mortem Signs: 1. Dermatitis; 2. Mange (sarcoptic), scabs with general areas of reddened, itchy or thickened skin; 3. Generalized lymphadenitis; 4. Tissue or organ degeneration; and\|or 5. Petechiae or ecchymotic hemorrhages in tissues, organs, or skin. Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses showing signs of extensive skin lesions and associated generalized or systemic changes for disposal under FSIS inspection. Special Notes: The following conditions might be confused with skin disease: (1)Market hogs over-scalded as a result of being in the scald vat for too long or at too high a temperature; (2)Erythema and bruising; (3) Frost-bite; (4) Hemophilic infection, fungal infections; (5)Vesicular diseases (e.g., FMD and Seneca Valley Virus (SVV)); and (6) Swine Circovirus. 41", "42 Ringworm (fungal dermatitis). Vesicles (Blisters). FMD is a vesicular disease, vesicles (blisters) are on snout; check tongue, feet, nipples. FMD is a foreign animal disease (FAD). M. Diamond Skin \u2013Skin Form of Swine Erysipelas Erysipelas is a disease of market hogs caused by the organism *Erysipelothrix rhusiopathiae*. A chronic form of erysipelas is recognized as \u201cdiamond skin\u201d disease (see 9 CFR 311.6).", "Diamond shaped skin lesions. Diamond shaped skin lesions on a scalded carcass after hair removal. Diamond shaped skin lesions at post-mortem. Post-Mortem Signs: 43", "1. Diamond shaped lesions, which may vary from acute to chronic; 2. Arthritis; 3. In acute disease, generalized lymphadenitis; 4. Petechial hemorrhage may be noticeable in lungs, kidneys, heart, or on outer surfaces; 5. Degeneration of tissues or organs; and\|or 6. Vegetative valvular endocarditis. Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses with the following signs of acute, systemic, or generalized diamond skin for disposal under FSIS inspection: 1. Numerous deep dark diamond skin lesions; 2. Petechial hemorrhages in the kidneys; 3. Hemorrhagic and congested lymph nodes; and\|or 4. Degeneration of organs. Special Note: \"Diamond skin\" is a common name for chronic stages of erysipelas in market hogs with chronic diamond skin lesions. When the lesions are limited to just the skin, as often the case, the sorter may identify skin lesions for removal under FSIS inspection. N. Fractures, Bruises, and Injuries, Septic and Non-Sepctic (See 9 CFR 311.14). Post-Mortem Signs: 1. Bruises, injuries, or fracture with hemorrhage into the tissues and involving regional or carcass lymph nodes; 2. Septic or toxic changes to organs; 3. Gangrene, strong odor; 4. Injection lesions; 5. Bruise showing hemorrhagic regional lymph nodes; 6. Brownish or dark discoloration of body tissues over whole carcass; or 7. Post-mortem rib fractures. Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses showing the following acute, systemic, or generalized defects for disposal under FSIS inspection: 1. Extensive, generalized bruising, discoloration that cannot be removed by trimming; or 2. Septic bruising or injuries that show associated systemic changes of septicemia or toxemia. Special Notes: Post-mortem fractures typically have no evidence of

hemorrhage near the fracture site. Post-mortem fractures, slight bruises, and healed rib fractures are quality defects that may be removed on the cut floor. O. Melanomas vs. Melanosis 44", "Melanin is a normal black pigment of the body (see 9 CFR 311.13). Melanosis is excessive melanin deposits or deposits in abnormal locations. Melanosis typically can be found in the lungs, spinal dura, skin, or lymph nodes draining other melanomas or melanin pockets. Such deposits must be removed from product for human food purposes. Melanomas are tumors consisting of melanin producing cells. Malignant tumors show evidence of metastasis in draining lymph nodes. Melanoma is a neoplasia of the naturally occurring melanocytes in the skin. Benign lesions (melanocytomas) and malignant lesions (malignant melanoma) occur, and these must be differentiated from melanosis. Laboratory analysis can be helpful in differentiating benign and malignant melanomas. Black tumors may be seen in the skin of any species. In market hogs these most often might be seen at the base of the ears, mid-back, tail-head and flanks. Certain breeds of market hogs are particularly prone to having melanosis and melanotic tumors. Melanosis (Pigmentation) of lung and liver tissue. 45", "Carcass with melanotic skin lesions. Sorters should check all draining lymph nodes. Melanoma (benign or malignant tumor). 46", "Pigmentation of lymph nodes; possible tumor. Notice melanotic patches of skin on the carcass. Check draining lymph nodes and viscera for evidence of melanosis or metastasis. Post-Mortem Signs: 1. Melanin pigment in lungs, liver, lymph nodes, or other organs; 2. Melanin in skin; 3. Melanin in sclera of eye; 4. Melanin associated with inflammation; 5. Metastasis (i.e., multiple tumors) to regional lymph nodes; 6. Metastasis to the lungs; and\or 7. Metastasis to the liver, spleen, and other internal organs. Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses with the following signs of acute, systemic, or generalized defects for disposal under FSIS inspection: 1. Generalized pigmentary deposits; 2. Melanin that cannot be removed or is impractical to remove, or that renders a carcass, organ, or part or the affected portion of a carcass, organ or part unfit for human food; 3. Evidence of abnormal tumor growth (i.e., metastasis-formation of multiple tumors); and 4. Tumors affecting the overall health or condition of the animal and carcass. Special Notes: Slight melanin deposits in spinal cord sheath (meninges) are normal. When including surface of the bones, the pigmented tissue must be removed when its appearance does not meet consumer expectations (9 CFR 311.1 and 311.13(b)). Slight or diffuse pigmentation of skin need not be removed unless tumorous or smearable. 47", "P. Icterus (Jaundice) Icterus represents an abnormal accumulation of yellowish bile pigments associated with the breakdown of blood that is stored in liver cells or the gall bladder (see 9 CFR 311.19). Post-Mortem Signs: 1. Degenerative changes in liver (e.g., pale, enlarged) and\or darkened spleen; 2. Lemon-yellow discoloration of connective tissues that are normally very white or pale including: a. Sclera (white part) of the eye, b. Tendons, c. Pleura (lining of the chest cavity), d. Peritoneum (lining of the abdominal cavity), e. Omentum (tissue that extends from the stomach to the adjacent organs in the abdominal cavity), f. Cut surface of abdominal wall fat, g. Joint surfaces, or h. Mesentery (fold of tissue attaching small intestines to the body wall). Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses that are icteric for disposal under FSIS inspection. Special Notes: Sorters should notify the PHV if they intend to hold icteric carcasses in the cooler pending final disposition. Q. Embryonal Nephroma Embryonal nephromas are rough, fibrous raised tumors of the kidney (see 9 CFR 311.11). Generally, they are benign

tumors and occur more commonly in young animals. Post-Mortem Signs: Presence of rough, fibrous tissue near the kidneys. 48","Benign Embryonal Nephroma. Embryonal Nephromas are typically benign (i.e. nonmalignant) congenital kidney tumors in swine. Disposal: Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses showing signs of acute, systemic, or generalized embryonal nephroma for disposal under FSIS inspection. R. Malignant Lymphoma Lymphoma is a neoplastic condition of the lymphocytes and is considered malignant (see 9 CFR 311.11). There are many manifestations of lymphoma, so it can be confused with other diseases, such as granulomas, abscesses, or other types of neoplasia. Post-Mortem Signs: 1. Gross enlargement of one or more lymph nodes with uniformly pale moist surface; 2. Gross enlargement of lymph node with a large yellow necrotic center; (e.g., mandibular lymph nodes or lymph nodes of the thoracic inlet); 3. Gross enlargement of lymph nodes with a dark red center; 4. Gross enlargement of liver and spleen; and\or 5. Focal or diffuse neoplastic growth or plaques on pleural ribs wall or peritoneal (i.e., inside abdominal wall). Disposal: Sorters are required to identify any carcass showing signs of malignant lymphoma. Regardless of the extent and distribution of the lymphoma, any evidence, just one lesion, of lymphoma requires disposal of the entire carcass and viscera. 49","Notice large lymph nodes with smooth surface indicative of malignant lymphoma in the head. Some carcasses with malignant lymphoma may exhibit lymph nodes in the neck exhibiting a yellow necrotic center like a hardboiled egg. Check remainder of carcass. Carcasses with any evidence of malignant lymphoma are condemned. Enlarged malignant lymphoma in renal lymph nodes inside carcass. Malignant lymphoma in mesenteric lymph nodes. 50","Malignant lymphoma infiltrating kidney in several locations. Notice several raised bumps or plaques. Lesions are often found on the ribs, diaphragm, and abdominal organs. Notice the smooth appearance of malignant lymphoma on cut surface. The normal outer lymph node and center are obliterated with many tumor cells. Malignant lymphoma infiltration of enlarged liver 51","S. Odors; Undetermined; Sexual Odor of Swine The carcass of a barrow market hog with retained testicle can exhibit a characteristic sexual odor (see 9 CFR 311.20). Sexual odor is rarely seen in market hogs less than 6 months of age. When present, there is a distinct pungent odor to the tissues. NOTE: Because boars and stags are not market hogs, they are not eligible for slaughter under the NSIS without a waiver under the Salmonella Initiative Program. Post-Mortem Signs: 1. Any sex odor of carcass or viscera of any market hog; and\or 2. Chemical or medicinal odors. Disposal: Sorters are required to identify any carcass that exhibits a pronounced sexual odor for disposal under FSIS inspection. However, if the sexual odor is less than pronounced, sorters may request the PHV to inspect the carcass to determine if the carcass may be passed for use as human food, as either cooked comminuted product or for rendering as lard. Special Notes: (1)A warm carcass should be considered to have a pronounced odor if sorters can smell the odor when they are several inches away from the carcass. (2)If the odor is less than pronounced, sorters will have to get very close to the carcass to smell the odor. T. Pale Soft Exudative Pork (PSE) Extensive PSE is a form of muscular degeneration (See 9 CFR 311.35. Post-Mortem Signs: Affected muscle tissue appears pale soft and watery in appearance. Tissue may have a slight sour smell. Lesions may appear in one or more large muscles to varying degrees. Disposal: Mild forms of PSE are histologically normal and the carcasses and parts are suitable for further processing. Sorters are required to identify localized defects for removal under FSIS inspection. Sorters are required to identify carcasses

showing signs of acute, systemic, or generalized PSE for disposal under FSIS inspection. U. Over-Scald Post-Mortem Signs: Carcasses showing signs of being over-scalded will have a cooked appearance and will usually have varying degrees of mutilation and contamination of tissues with scald vat water. Disposal: Sorters are required to identify contaminated parts (e.g., broken skin) for removal under FSIS inspection. Sorters are required to identify carcasses that are severely over- 52", "scalded (e.g., the carcass has undergone thermal changes that may obscure other adulterating conditions like septicemia) for disposal under FSIS inspection. V. Classical Swine Fever (Hog Cholera) Classical Swine Fever (Hog Cholera) is a reportable FAD not found in the United States since 1978. Should hog cholera reappear, multiple signs of fever, illness, and inflammation will be seen at ante-mortem and post-mortem. Establishments are required to immediately notify FSIS inspectors if they identify, while conducting sorting activities, an animal or carcass that they suspect has a reportable or foreign animal disease (9 CFR 309.19(e)). Upon notification by the establishment, the PHV will notify APHIS. W. African Swine Fever African Swine Fever (ASF) is also a reportable FAD not found in the United States. ASF is currently affecting swine in other countries around the world. Notable signs include high death loss, fever, and illness. Establishments are required to immediately notify FSIS inspectors if they identify, while conducting sorting activities, an animal or carcass that they suspect has a reportable or foreign animal disease (9 CFR 309.19(e)). For more information on ASF, see the APHIS website: <https://www.aphis.usda.gov/aphis/ourfocus/animalhealth/animal-disease-information/swinedisease-information/african-swine-fever/african-swine-fever> X. Brucellosis in Feral or Other Swine Classes Swine brucellosis is a reportable disease rarely found in confinement raised market hogs. Swine brucellosis may be found in other classes of swine especially mature breeding swine or feral swine. Swine brucellosis is a potential disease of public health concern and occupational health. Human infections are associated with exposure to reproductive organs (e.g. uterus, testicles). Brucellosis in market hogs has few post mortem lesions. Establishments are required to immediately notify FSIS inspectors if they identify, while conducting sorting activities, an animal or carcass that they suspect has a reportable or foreign animal disease (9 CFR 309.19(e)). Special Notes: Should an establishment desire to slaughter other classes of swine (e.g. sows, boars, and feral swine) under the NSIS, a waiver would be required. 53" "IX. REFERENCES A. The list is intended to be informational and is not an endorsement or approval of any specific test kit, regardless of its inclusion in the list. FSIS does not specifically endorse any of the mentioned test kits or products and acknowledges that equivalent test kits or products may be available for laboratory use. Likewise, FSIS does not require the use of any specific test kit, including those incorporated into FSIS\u2019s Microbiology Laboratory Guidebook methods. Instead, establishments and laboratories should choose test kits that are: 1)Validated for testing relevant foods by a: a) Recognized independent body (i.e., AOAC, AFNOR, MicroVal, NordVal), b) U.S. regulatory body (i.e., FSIS MLG or FDA BAM), or c) International Organization for Standardization (ISO) process 2)In addition, the validated method should be: a)Fit for the intended purpose and application (e.g., validated for the appropriate matrix and sample size to detect the appropriate foodborne pathogen), and b)Performed per the conditions of the validated protocol by a laboratory that assures the quality of the analytical results. The table below contains a list of foodborne pathogen test kits that are validated by recognized independent organizations (i.e., AOAC, AFNOR, MicroVal, NordVal) and therefore meet criterion 1a above. However, the test kits in this list are not necessarily equivalent or appropriate for all testing applications. FSIS intends to update validated test kit lists on a quarterly basis. # Method"]}]

The list is intended to be informational and is not an endorsement or approval of any specific test kit, regardless of its inclusion in the list. FSIS does not specifically endorse any of the mentioned test kits or products and acknowledges that equivalent test kits or products may be available for laboratory use. Likewise, FSIS does not require the use of any specific test kit, including those incorporated into FSIS\u2019s Microbiology Laboratory Guidebook methods. Instead, establishments and laboratories should choose test kits that are: 1)Validated for testing relevant foods by a: a) Recognized independent body (i.e., AOAC, AFNOR, MicroVal, NordVal), b) U.S. regulatory body (i.e., FSIS MLG or FDA BAM), or c) International Organization for Standardization (ISO) process 2)In addition, the validated method should be: a)Fit for the intended purpose and application (e.g., validated for the appropriate matrix and sample size to detect the appropriate foodborne pathogen), and b)Performed per the conditions of the validated protocol by a laboratory that assures the quality of the analytical results. The table below contains a list of foodborne pathogen test kits that are validated by recognized independent organizations (i.e., AOAC, AFNOR, MicroVal, NordVal) and therefore meet criterion 1a above. However, the test kits in this list are not necessarily equivalent or appropriate for all testing applications. FSIS intends to update validated test kit lists on a quarterly basis. # Method Name Target Organism(s) Manufacturer External Validation Validated Matrices Validated Test Portion Size C002 BAX System Real-Time PCR Assay for Campylobacter jejuni, coli, and lari Campylobacter jejuni; Campylobacter coli; Campylobacter lari Qualicon Diagnostics LLC, a Hygiena Company NordVal # 039 Faeces on cloacae swabs (levels above 100 cfu\g) N\A C003 BAX\u00ae System Real-Time PCR Assay for Campylobacter jejuni, coli, and lari Campylobacter

The list is intended to be informational and is not an endorsement or approval of any specific test kit, regardless of its inclusion in the list. FSIS does not specifically endorse any of the mentioned test kits or products and acknowledges that equivalent test kits or products may be available for laboratory use. Likewise, FSIS does not require the use of any specific test kit, including those incorporated into FSIS\\u2019s Microbiology Laboratory Guidebook methods. Instead, establishments and laboratories should choose test kits that are: 1)Validated for testing relevant foods by a: a)Recognized independent body (i.e., AOAC, AFNOR, MicroVal, NordVal), b) U.S. regulatory body (i.e., FSIS MLG or FDA BAM), or c) International Organization for Standardization (ISO) process 2)In addition, the validated method should be: a)Fit for the intended purpose and application (e.g., validated for the appropriate matrix and sample size to detect the appropriate foodborne pathogen), and b)Performed per the conditions of the validated protocol by a laboratory that assures the quality of the analytical results. The table below contains a list of foodborne pathogen test kits that are validated by recognized independent organizations (i.e., AOAC, AFNOR, MicroVal, NordVal) and therefore meet criterion 1a above. However, the test kits in this list are not necessarily equivalent or appropriate for all testing applications. FSIS intends to update validated test kit lists on a quarterly basis. # Method Name Target Organism(s) Manufacturer External Validation Validated Matrices Validated Test Portion Size L001 3M Petrifilm Environmental Listeria (EL) Plate Listeria monocytogenes, Listeria innocua, and Listeria welshimeri 3M Food Safety AOAC-PTM # 030601 (Environmental swabs or sponges enriched in 5mL of buffered peptone water) stainless steel, ceramic tile, N\\A sealed concrete L006 ACTERO Listeria Enrichment Media Listeria spp. FoodChek Systems, Inc AOAC-PTM # 111201 Frankfurters, smoked turkey breast (125 g), cured ham (125 g), raw frozen salmon, cold smoked salmon, frozen 25g except where noted in \\\"Validated Matrices\\" cooked shrimp, cooked shrimp, ice cream, pasteurized milk, pasteurized 2% milk, soft Mexican-style cheese, bagged spinach, soft fresh ricotta cheese, liquid whole eggs, ceramic tile, rubber, sealed concrete, stainless steel, plastic L010 AL\\Agar (Detection) Listeria monocytogenes and Listeria spp. BIO-RAD AFNOR # BRD 07\\16 -01\\09 All human food products (by performing validation assays on a broad range of foods) and industrial 25g L011 AL Enumeration Listeria

The list is intended to be informational and is not an endorsement or approval of any specific test kit, regardless of its inclusion in the list. FSIS does not specifically endorse any of the mentioned test kits or products and acknowledges that equivalent test kits or products may be available for laboratory use. Likewise, FSIS does not require the use of any specific test kit, including those incorporated into FSIS\u2019s Microbiology Laboratory Guidebook methods. Instead, establishments and laboratories should choose test kits that are: 1)Validated for testing relevant foods by a: a)Recognized independent body (i.e., AOAC, AFNOR, MicroVal, NordVal), b)U.S. regulatory body (i.e., FSIS MLG or FDA BAM), or c) International Organization for Standardization (ISO) process 2)In addition, the validated method should be: a)Fit for the intended purpose and application (e.g., validated for the appropriate matrix and sample size to detect the appropriate foodborne pathogen), and b)Performed per the conditions of the validated protocol by a laboratory that assures the quality of the analytical results. The table below contains a list of foodborne pathogen test kits that are validated by recognized independent organizations (i.e., AOAC, AFNOR, MicroVal, NordVal) and therefore meet criterion 1a above. However, the test kits in this list are not necessarily equivalent or appropriate for all testing applications. FSIS intends to update validated test kit lists on a quarterly basis. # Method Name Target Organism(s) Manufacturer External Validation Validated matrices Validated Test Portion Size EC003 Assurance GDS for E. coli O157:H7 E. coli O157:H7 BioControl Systems AOAC-OMA # 2005.04 Raw ground beef, beef trim, orange juice, apple juice, fresh 25g EC004 Assurance GDS Shigatoxin Genes E. coli O157:H7 and E. coli O157:H7 nonmotile (NM) BioControl Systems AOAC-OMA # 2005.05 Raw ground beef, beef trim, orange juice, apple juice, fresh vegetables, and sprout process water 25g EC005 Assurance\u00ae Enzyme Immunoassay (EIA) E. coli O157:H7 (EHEC) BioControl Systems AOAC-OMA # 996.10 Dairy

The list is intended to be informational and is not an endorsement or approval of any specific test kit, regardless of its inclusion in the list. FSIS does not specifically endorse any of the mentioned test kits or products and acknowledges that equivalent test kits or products may be available for laboratory use. Likewise, FSIS does not require the use of any specific test kit, including those incorporated into FSIS\u2019s Microbiology Laboratory Guidebook methods. Instead, establishments and laboratories should choose test kits that are: 1)Validated for testing relevant foods by a: a)Recognized independent body (i.e., AOAC, AFNOR, MicroVal, NordVal), b)U.S. regulatory body (i.e., FSIS MLG or FDA BAM), or c) International Organization for Standardization (ISO) process 2)In addition, the validated method should be: a)Fit for the intended purpose and application (e.g., validated for the appropriate matrix and sample size to detect the appropriate foodborne pathogen), and b)Performed per the conditions of the validated protocol by a laboratory that assures the quality of the analytical results. The table below contains a list of foodborne pathogen test kits that are validated by recognized independent organizations (i.e., AOAC, AFNOR, MicroVal, NordVal) and therefore meet criterion 1a above. However, the test kits in this list are not necessarily equivalent or appropriate for all testing applications. FSIS intends to update validated test kit lists on a quarterly basis.

..... 18", "3 Preface What is the purpose of this Compliance Guideline? The purpose of this compliance guideline is to outline the documentation that establishments need to submit in support of label applications for products that bear animal raising claims. The Food Safety and Inspection Service (FSIS) is the Agency in USDA with the responsibility for ensuring that the labeling of meat and poultry products is truthful and not misleading. Labeling bearing claims referring to the way that the source animal for a meat or poultry product was raised need to be evaluated and approved by FSIS prior to use. For the past 25 years, FSIS has evaluated animal raising claims by considering information on animal raising practices submitted by companies as part of their label approval requests. The Agency has approved such claims if the animal raising information submitted with the label application supported the claim being made and the claim is truthful and not misleading. FSIS developed this guideline to respond to numerous requests to the Labeling Program and Delivery Staff (LPDS) through phone calls, askFSIS questions, and other correspondence regarding the type of information needed to support the approval of labels bearing animal raising claims. This guideline is intended to facilitate the approval process for labels bearing animal raising claims. The information in this guideline is provided as guidance to assist meat and poultry establishments and is not legally binding from a regulatory perspective. Who is this guideline designed for? This guideline is for establishments that are designing or modifying meat or poultry product labels with animal raising claims. The establishment must determine what supporting documentation is required for the various types of animal raising claims. This guideline will assist the establishment in making this determination. How will FSIS verify whether establishments meet requirements related to this guideline? FSIS in-plant personnel verify that establishments comply with labeling regulations, when performing the General Labeling task assigned through the Public Health Information System (PHIS). For product bearing animal raising claims, in-plant personnel verify whether establishments maintain an FSIS approved label on file. Animal raising claims are special statements and claims

that establishments are Key Points The following are examples of animal raising claims that are required to be approved by FSIS prior to use in commerce: 1. Raised Without Antibiotics 2. Organic 3. Grass Fed 4. Raised Without the Use of Hormones", "4 required to submit to FSIS for approval for compliance with 9 CFR 412.1, USDA\ufe0f's Label Approval Regulations. Changes made to the guideline from the previous version After reviewing the comments received, FSIS has revised the guideline by section as follows: \u2022 Product Labeling: Use of Animal-Raising Claims on the Labels of Meat or Poultry Products o Added information about labeling needed for products bearing claims certified by third-party organization, including when products certified as \u201corganic\u201d need to disclose the certifying entity\ufe0f's website address on the product label. o Added information about carrying claims forward on additional products. o Removed age claims section because establishments are not using these claims. o Animal Welfare and Environmental Stewardship Claims: o Added descriptive language or information (terminology) that should accompany these claims to explain the meaning of the claim to consumers, including the type of information that needs to appear on the label when the product is certified by a third-party organization. o Breed claims: o Added information about carrying these claims forward to other products. o Living- or Raising-Condition Claims: o Reorganized section for clarity regarding labeling terminology and recommended documentation for approval. o Added information about additional terminology that typically accompanies these claims to explain the meaning of the claim to consumers, including where the information must appear on the label. o Added information on the use of \u201cFree Range\u201d and synonymous claims (\u201cFree Roaming,\u201d \u201cPasture Fed,\u201d Pasture Grown,\u201d \u201cPasture Raised,\u201d and \u201cMeadow Raised\u201d) on labels of poultry products and the documentation needed to substantiate these claims. o Raised Without Antibiotics \u2013 Livestock\Red Meat or Poultry: o Added \u201cRaised Antibiotic Free\u201d and \u201cNo added antibiotics\u201d as examples of claims that may be used to disclose the fact that animals were not administered antibiotics at any point in the animal production process. o Added information on claims that include the term \u201csub-therapeutic antibiotics\u201d to ensure that consumers understand that the claim means that antibiotics may only be administered in the event of an illness and includes the circumstances for which FSIS will approve labels bearing these claims. o Raised Without Hormones (No Hormones Administered or No Steroids Administered): o Updated information to clarify that FSIS will no longer require a qualifying statement on pork products labeled with \u201ca raised without hormones\u201d claim because Federal law permits the use of certain hormones in swine, e.g., for gestation.", "5 o Added new examples of this type of claim. o Updated information to clarify why a qualifying statement is necessary for products made from a kind or species for which Federal law prohibits hormone use and to emphasize that this information must be displayed on the label in a manner that is likely to be read and understood by the ordinary individual for FSIS to approve the claim.. o Third-Party Certification: o Added information about documentation needed to support labels bearing animal raising claims that have been \u201cverified\u201d or \u201ccertified\u201d by third-party organizations. o Added information about \u201corganic\u201d claims, including other claims that could be substantiated with an Organic Certificate. o Added section on procedures for adding an additional supplier for a label with animal-raising claims that was previously approved by FSIS. The updated guideline is posted at:

<https://www.fsis.usda.gov/wps/portal/fsis/topics/regulatory-compliance/complianceguides-index/>. FSIS will update this document, as necessary. What if I still have questions after I read this guideline? If the desired information cannot be found within the Compliance Guideline, FSIS recommends that users search the publicly posted Questions & Answers (Q&As) in the askFSIS database or submit questions through askFSIS. Documenting the questions helps FSIS improve and refine present and future versions of the Compliance Guideline and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in the fields provided: SubjectField: \u201cDocumentation Needed to Substantiate Animal Raising Claims\u201d QuestionField: Enter question with as much detail as possible. ProductField: Select Labeling from the drop-down menu. CategoryField: Select Labeling Regulations, Policies and Claims from the dropdown menu. Policy Arena: Select Domestic (U.S.) only from the drop-down menu. When all fields are complete, press Continue. Congressional Review Act Pursuant to the Congressional Review Act at 5 U.S.C. 801 et seq., the Office of Information and Regulatory Affairs has determined that this guideline is not a \u201cmajor rule,\u201d as defined by 5 U.S.C. 804(2).", "6 Product Labeling: Use of the Animal Raising Claims on the Labels of Meat and Poultry Products A Federal establishment is required to use labels that are in compliance with the Federal Meat Inspection Act (FMIA; 21 U.S.C. \u00a7 601, 607) and the Poultry Products Inspection Act (PPIA; 21 U.S.C. \u00a7 451, 457) (the Acts), and the implementing regulations. Requirements include all mandatory labeling requirements as prescribed in Title 9 of the Code of Federal Regulations (CFR) section 317.2 and Part 381 Subpart N. Although FSIS does not exercise its authority of prior label approval to point of purchase materials (e.g., pamphlets and placards) displayed in conjunction with products sold at retail and bearing animal raising claims, FSIS does require these materials be neither false or misleading, in compliance with the Acts and Federal regulations. As stated in 9 CFR 412.1, labels with special statements and claims are required to be approved by FSIS prior to use in commerce. Labels bearing animal raising claims are required to be submitted to LPDS with specific documentation to support all animal raising claims that appear on that label. Examples of animal raising claims include, but are not limited to: Raised Without Antibiotics, Grass Fed, Free-Range, and Raised Without the Use of Hormones. For most animal raising claims, the documentation typically needed to support these claims is: 1. A detailed written description explaining the controls used for ensuring that the raising claim is valid from birth to harvest or the period of raising being referenced by the claim; 2. A signed and dated document describing how the animals are raised which may include feed formulations (e.g., vegetarian fed, raised without antibiotics, grass fed), to support that the specific claim made is truthful and not misleading; 3. A written description of the product tracing and segregation mechanism from time of slaughter or further processing through packaging and wholesale or retail distribution; 4. A written description for the identification, control, and segregation of nonconforming animals\product; and 5. If a third-party certifies a claim, a current copy of the certificate from the certifying organization. NOTE: If the claim was certified by a third-party certifying organization, FSIS will not approve the label bearing the claim if it does not include the certifying entities name, website address,<sup>1</sup> and logo, when the organization has a logo. An asterisk or other symbol must connect the claim to this information.  
1 Products certified as \u201corganic\u201d would not need to disclose a website address on the label, except when the address is required under 7 CFR Part 205.", "7 In general, a

purchased product bearing an approved animal raising claim may be used to support the claim in lieu of numbers 1 \u2013 3 above. If a company purchases product bearing animal raising claims and would like to carry forward those claims onto its labeled product, the company needs to provide a copy of the purchased product label and segregation procedures when entering their federal establishment. However, companies cannot carry forward certified claims, logos and\or websites from purchased products that are certified by a third-party entity unless the companies that are carrying the claim forward are also under that same certification. Companies cannot carry forward USDA organic claims, logos and\or websites without being certified organic themselves. Types of Animal Raising Claims and Guideline on the Documentation Needed to Substantiate the Claims Animal Welfare and Environmental Stewardship These claims describe how animals are raised based on the care they receive by the producer or how the producer maintains the land and replenishes the environment. FSIS has not defined these claims in regulations or policy guidelines. For animal welfare claims, such as \u201cRaised with Care,\u201d or environmental stewardship claims, such as \u201cSustainably Raised,\u201d FSIS will only approve a claim if a statement is provided on the label showing the name of the entity that established the standard and includes additional terminology explaining the meaning of the claim for consumers, e.g., \"TMB Ranch Defines Raised with Care\Sustainably Raised as [explain the meaning of the claim on the label].\" If the entity has a website that describes the standards used to define the claim, the label may provide the website address instead of explaining what the claim means on the product label, e.g., \u201cRaised with Care as defined by TMB Ranch at: [website address].\u201d As an alternative, animal welfare and environmental stewardship claims can be certified by a third-party certifying organization that posts the standards used to define the claim on its website. If the claim is certified by a third-party certifying organization, FSIS will not approve the label bearing the claim if it does not include the certifying entities name, website address, and logo, when the organization has a logo. The claims may appear on any panel of the package. The additional terminology that explains the meaning of the claim may appear with the claim or may be connected to the claim by an asterisk or another symbol and placed elsewhere on the same panel that bears the claim. For example, if a claim is made on the principal display panel (PDP), the part of the label most likely to be seen by consumers when offered for retail sale, the explanation of the claim\u2019s meaning may be placed with the claim or placed elsewhere on the PDP provided the claim and explanation are connected by a symbol. If the claim is certified by a third-party certifying organization, an asterisk or other symbol must connect the claim to the certifying entities name, website address, and\or logo, when the organization has a logo, for FSIS to be able to approve the label. Examples of these types of claims include, but are not limited to: Humanely Raised\*, Sustainably Farmed\*, and Raised with Environmental Stewardship\*.,"8 \*TMB Ranch defines \u201cHumanely Raised\u201d\|\u201dSustainably Farmed\Raised with Environmental Stewardship\u201d as [insert description of standards used to define the claim] Documentation needed: 1. A detailed written description explaining the meaning of the animal welfare or environmental stewardship claim and the controls used for ensuring that the raising claim is valid from birth to harvest; or the period of raising being referenced by the claim; 2. A signed and dated document describing how the animals are raised to support that the claims are not false or misleading; 3. A written description of the product tracing and segregation mechanism from time of slaughter or further processing through

packaging and wholesale or retail distribution; and 4. A written description for the identification, control, and segregation of nonconforming animals\product (e.g., how animals not raised in accordance with the specific animal welfare guidelines or stewardship program are segregated from animals eligible to bear the claim). Breed Breed claims refer to the declaration of a specific breed of livestock or poultry. Examples of this type of claim include, but are not limited to: Angus, Wagyu (American Kobe), Hereford, Berkshire, Duroc, Muscovy, Silkie, and heritage poultry, pork or beef breeds. Documentation needed: 1. A signed and dated document that substantiates the breed claim, e.g., under a Agricultural Marketing Service (AMS) Certified Meat and Poultry Program or a certificate from a breed organization; 2. A written description of the product tracing and segregation mechanism from time of slaughter or further processing through packaging and wholesale or retail distribution; 3. Documentation to support the breed by phenotype (for example, hide color) or genotype (traceable to one registered parent or two registered grandparents with a breed association); and 4. A written description for the identification, control, and segregation of nonconforming animals\product. Alternatively, a purchased product label may be used in lieu of numbers 1 \u2013 3 above. If a company purchases product bearing a breed claim and would like to carry forward the claim on to their product, the company needs to provide a copy of the purchased label and segregation procedures for product entering the federal establishment when submitting for label approval.

NOTE: See label example", "9 Diet Diet claims refer to what animals are fed prior to harvest and processing. These claims require that the animals only eat the diet claimed for the lifetime of the animal, with the exception of milk consumed prior to weaning. FSIS considers Grassfed, Grass Fed and Grass-Fed synonymous terms. \u201cGrass Fed\u201d or \u201c100% Grass Fed\u201d claims may only be applied to meat and meat product labels derived from cattle that were only (100%) fed grass (forage) after being weaned from their mother\u2019s milk. The diet must be derived solely from forage, and animals cannot be fed grain or grain by-products and must have continuous access to pasture during the growing season until slaughter. This means 100% grass-fed animals are never confined to a feedlot. Forage consists of grass (annual and perennial), forbs (e.g., legumes, Brassica), browse, or cereal grain crops in the vegetative (pre-grain) state. Hay, haylage, baleage, silage, crop residue without grain, and other roughage sources may also be included as acceptable feed sources. Routine mineral and vitamin supplementation may also be included in the feeding regimen. If incidental supplementation occurs due to inadvertent exposure to non-forage feedstuffs or to ensure the animal\u2019s wellbeing at all times during adverse environmental or physical conditions, the producer should provide a signed and dated document to the establishment attesting the above incident is not a routine occurrence. The establishment should include this information as part of the labeling documentation verifying the product qualifies for a grass fed claim. When animals have less than 100-percent access to grass or forage the partial \u201cgrass fed\u201d claim must accurately reflect the circumstances of raising, e.g., \u201cMade from cows fed 85% grass and 15% corn.\u201d The claim \u201cGrass Finished\u201d is not the same as \u201cGrass Fed\u201d because animals that are \u201cgrass finished\u201d can be fed grain, in which case the claim \u201cGrain Fed, Grass Finished\u201d would be truthful and not misleading. Historically, the AMS Grass (Forage) Fed Marketing Claim Standard was considered one form of proof to FSIS that the claim \u201cgrass fed\u201d was truthful and not misleading. In January 2016, AMS withdrew the standard. This change did not change

FSIS\u2019s documentation requirements for companies wishing to label their products as \u201cGrass Fed.\u201d Examples of this type of claim include, but are not limited to: Grass (Forage) Fed, Grain Fed, Vegetarian Feed, Raised Using Vegetarian Feeds [This means all vegetable feeds and no animal products (e.g., whey) are fed to the animal.], Raised Using Vegetarian Feeds (with a disclaimer to clarify animal products are fed to the animal for a certain period of time, e.g., \u201cexcept for dairy products fed from birth to eight weeks\u201d or \u201cafter 8 weeks\u201d), and Fed No Animal By-Products. Documentation needed: 1. A detailed written description explaining controls for ensuring that the raising claim is valid from birth to harvest or the period of raising being referenced by the ", "10 claim; (e.g., controls to ensure cattle that are supposed to be raised 100% grass fed are not fed grains); 2. A signed and dated document describing the diet of the animals to support that the claims are not false or misleading; 3. A written description of the product tracing and segregation mechanism from time of slaughter or further processing through packaging and wholesale or retail distribution; and 4. A written description for the identification, control, and segregation of nonconforming animals\product. As an alternative, a producer may use the USDA Process Verified Program (PVP) (carried out by AMS) to verify their product meets their own grass-fed standard in lieu of documentation needed for 1-4 above. The USDA PVP is a voluntary, user-fee verification service that offers applicants a unique way to market their products to customers using clearly defined, implemented, and transparent process points. An applicant\u2019s program may include one or more agricultural processes or portions of processes independently verified by a qualified AMS auditor. Examples of process points include, but are not limited to: adherence to a recognized standard or one created by a company or organization; definitions included within this guidance; a production, raising and\or handling practice that provides specific information to consumers to enable them to make informed decisions on the products that they buy; or a characteristic, practice, or requirement that is specifically requested by a customer or consumer. AMS auditors conduct a comprehensive review of a company\u2019s program, which includes an on-site audit of all facilities and phases of the operation that impact process verified points. Additional information about the USDA PVP service, shield, certificate, and official listing are available at [www.ams.usda.gov/services/auditing/process-verified-programs](http://www.ams.usda.gov/services/auditing/process-verified-programs). There are a number of private third-party certification programs that accomplish the same objectives. If the claim is certified by a third-party organization, an asterisk or other symbol must connect the claim to the certifying entities name, website address, and\or logo, when the organization has a logo. NOTE: See label example Living\Raising\Raising Conditions These claims refer to the environment in which the animals or birds were raised during their lifespan. Examples of this type of claim include but are not limited to: Cage or Crate Free, Free Range\*\*, Not Confined, Free Roaming, Pasture Fed, Pasture Grown, Meadow Raised, and Pasture Raised. NOTE: For all of the above claims, additional terminology is necessary on the label to define its meaning on livestock products and to convey that the animals were never confined to a feedlot. Because FSIS has not defined these claims in the regulations or policy guidelines, nearly all living\raising conditions claims need to describe the standards used to define", "11 that claim as applied to that particular product, e.g., \u201cCage free. Chickens were never confined to cages during raising.\u201d The information must appear with the claim or be connected by a symbol on the same panel on which the claim appears. As an alternative, these living\raising claims can be certified by a third-party certifying organization

that posts its standards for defining the claim on its website. If the claim is certified by a third-party certifying organization, FSIS will not approve the label bearing the claim if it does not include the certifying entity's name, website address, and logo, when the organization has a logo. An asterisk or other symbol must connect the claim to this information. \*\*Based on consultations with AMS, FSIS determined that additional terminology is not needed on the label for the claim Free Range or synonymous claims (\u201cFree Roaming,\u201d \u201cPasture Fed,\u201d Pasture Grown,\u201d \u201cPasture Raised,\u201d and \u201cMeadow Raised\u201d) on poultry products. However, for FSIS to approve these claims, additional documentation must be submitted to substantiate the claim. Specific details about what additional information is needed is provided below. Documentation needed: 1. A detailed written description explaining controls for ensuring that the animals are raised in a manner consistent with the meaning of the raising claim that is valid from birth to harvest or the period of raising being referenced by the claim. 2. A signed and dated document describing how the animals are raised to support that the claims are not false or misleading; 3. A written description of the product tracing and segregation mechanism from time of slaughter or further processing through packaging and wholesale or retail distribution; and 4. A written description of the identification, control, and segregation of nonconforming animals\product. As part of 1 or 2 above, for the claim Free Range on poultry products, the documentation must describe the housing conditions for the birds and demonstrate continuous, free access to the outside throughout their normal growing cycle. During the winter months in a northern climate, birds are not free range if they stay in poultry housing or coops all winter. Producer documentation to support the use of the claim for birds raised in a northern climate during winter months would also need to describe the housing conditions for the birds and demonstrate continuous, free access to the outside throughout their normal growing cycle. As part of 1 or 2 above, for the claims Free Roaming, Pasture Fed, Pasture Grown, Pasture Raised, and Meadow Raised on meat or poultry products, documentation that will typically substantiate these claims will show that the animals or birds have continuous, free access to the outdoors throughout their usual grow-out period. For ruminants, this means the entire grazing season for the geographical area.

NOTE: See label example", "12 Negative Antibiotics Use \u2013 Livestock\Red Meat Raised Without Antibiotics: To use this claim, source animals cannot be administered antibiotics in their feed, water or by injections at any point in the production process. This includes ionophores which are recognized as antibiotics by FSIS. Examples of this type of claim include, but are not limited to: Raised Without Antibiotics, No Antibiotics Administered, No Added Antibiotics, No Antibiotics Ever and Raised Antibiotic Free. No Sub-Therapeutic Antibiotics: FSIS will approve a claim that states that animals have not been administered subtherapeutic antibiotics if the claim is part of a complete claim that explain what the term \u201bsub-therapeutic\u201d means, e.g., \u201cNo sub-therapeutic antibiotics. Animals do not receive antibiotics on a daily basis; animals only receive antibiotics in the case of illness.\u201d Other examples of this claim that FSIS is likely to find to be truthful and not misleading include: \u201cBeef Raised with No Sub-Therapeutic Antibiotics Ever, animals may be given antibiotics for the treatment of illness\u201d or \u201cBeef Raised with No Sub-Therapeutic Antibiotics, Animal do not receive antibiotics on a daily basis only in the case of illness.\u201d Documentation needed: 1. A detailed written description explaining controls for ensuring that the animals are not given antibiotics from birth to harvest or the period of raising being

referenced by the claim including feed formulation; 2. A signed and dated document describing how the animals are raised to support that the claims are not false or misleading; 3. A written description of the product tracing and segregation mechanism from time of slaughter or further processing through packaging and wholesale or retail distribution; and 4. A written description for the identification, control, and segregation of nonconforming animals\product (e.g., if beef raised without the use of antibiotics need to be treated with antibiotics due to illness). NOTE: See label example Negative Antibiotics Use \u2013 Poultry Raised Without Antibiotics For FSIS to find this claim to be truthful and not misleading, source animals cannot be administered antibiotics in their feed, water, or by injections. Animals cannot be administered ionophores, which are recognized as antibiotics by FSIS. Examples of this type of claim include: Raised Without Antibiotics, No Antibiotics Administered, No Added Antibiotics, No Antibiotics Ever, and Antibiotics Free. No Sub-Therapeutic Antibiotics:","13 This claim requires additional explanation on the label to ensure consumers understand antibiotics will be administered to the animals in the event of illness. Examples of this claim include: \u201cTurkey Raised with No Sub-Therapeutic Antibiotics Ever, birds may be given antibiotics for the treatment of illness\u201d or \u201cChicken Raised with No SubTherapeutic Antibiotics, birds do not receive antibiotics on a daily basis only in the case of illness.\u201d Documentation needed: 1. A detailed written description explaining controls for ensuring that the raising claim is valid from birth to harvest; or the period of raising being referenced by the claim; 2. A signed and dated document describing how the animals are raised without antibiotics to support that the claims are not false or misleading; 3. A written description of product tracing and segregation mechanism from time of slaughter or further processing through packaging and wholesale or retail distribution; and 4. A written description for the identification, control, and segregation of nonconforming animals\product (e.g., if chicken raised without the use of antibiotics need to be treated with antibiotics due to illness). In addition to the documentation listed above, the establishment needs to submit a company letter (signed and on company letterhead) answering the following questions: 1. Do you use antibiotics pre-hatch in any way with respect to the eggs that you hatch for the poultry that will bear the claim? If so, please describe how you use antibiotics? 2. Do you inject any vaccines in ovo? If so, please state whether any of the vaccines includes an antibiotic. If any of them does, please state what antibiotics are used, what the antibiotics are used for, and in what amount they are used. 3. Do you inject any antibiotics in ovo? If so, please state what antibiotics are used, what the antibiotics are used for, and in what amount they are used. What is the withdrawal time for the antibiotics? 4. Have you verified that the poultry that you use to produce your products was not derived from eggs or poultry that were injected or otherwise treated in any way with antibiotics? If so, how have you verified these conclusions? NOTE: See label example Negative Hormones Use Under Federal law, hormones are only approved for use in beef cattle, swine\*\*\*, and lamb production. There are no hormones approved for use in the production of poultry, goat, veal calves, mature sheep, or exotic, non-amenable species (such as bison, buffalo, elk, and venison). Thus, additional terminology is necessary on these labels to convey that Federal law prohibits hormone use in these species.", "14 FSIS will only approve a negative hormone claim on products made from a kind or species for which Federal law prohibits hormone use when it is accompanied by the qualifying statement: \u201cThere are no hormones approved for use in (kind or species [poultry, goat, veal, mature sheep, or exotic, non-amenable]) by Federal

Regulations.\u201d The qualifying statement must be prominently and conspicuously displayed on the label, e.g., it appears adjacent to the claim or is in type at least one-third the height, in accordance with 9 CFR 317.2(b) for meat products or 9 CFR 381.116(b) for poultry products. As for any labeling claim, FSIS confirms compliance with these regulations during the label approval process. \*\*\*NOTE: In the previous draft of this guideline, FSIS stated that no hormones had been approved for use in the production of swine. After additional research, FSIS has found that there are several hormones approved by the Food and Drug Administration and marketed by drug makers to be used in swine in the United States for various reasons (e.g., gestation). Establishments do not need to resubmit their labels for approval to remove the previously required disclaimer statement from pork product labels. The change can be made generically under 9 CFR 412.1. Examples of this type of claim include: Raised Without Added Hormones, No Added Hormones Administered, Raised Without Steroids. Documentation needed: 1. A detailed written description explaining controls for ensuring the animals are raised without hormones or steroids to support the claim is valid from birth to harvest; or the period of raising being referenced by the claim; 2. A signed and dated document describing how the animals are raised (e.g., without the use of hormones) to support that the claims are not false or misleading; 3. A written description of the product tracing and segregation mechanism from time of slaughter or further processing through packaging and wholesale or retail distribution; and 4. A written description for the identification, control, and segregation of nonconforming animals\product. NOTE: See label example Source\Traceability This type of claim demonstrates how the animal can be traced back to its farm of origin from birth to slaughter\harvest. Examples of this type of claim include: Source Verified and Traceable to [Name of Farm of Origin]. Documentation needed: 1. A detailed written description explaining controls for ensuring the source of the animal can be verified from birth to harvest or the period of raising being referenced by the claim; 2. A signed and dated document describing how the animals are raised to support that the claims are not false or misleading;","15 3. A written description of the product tracing and segregation mechanism from time of slaughter or further processing through packaging and wholesale or retail distribution; and 4. A written description for the identification, control, and segregation of nonconforming animals\product; and 5. Live animal raising records demonstrating how individual animals or a group of animals are identifiable and traceable to their farm or ranch of birth, and if verified, the individual or entity verifying the claim. NOTE: See label example Third-Party Certification Generally, FSIS accepts animal raising claims verified by a third-party auditing or certifying program. The standards for acceptance of the third-party certifier need to be credible and reliable. FSIS evaluates certifiers\u2019 acceptance standards as necessary to assess suitability for animal raising claims on labels. The label bearing the claim needs to include the certifying entity\u2019s name, website address, and logo, when the organization has a logo. An asterisk or other symbol must connect the claim to this information. Examples of this type of claim include but are not limited to: USDA PVP (administered by AMS), Animal Welfare Approved (AWA), or GAP Step ratings (Global Animal Partnership (GAP)). Documentation needed: 1. A current copy of the certificate; and 2. A written description of the product tracing and segregation mechanism from time of slaughter or further processing through packaging and wholesale or retail distribution. NOTE: If used in conjunction with any other animal raising claim(s) that are not covered by the third-party organization certification, refer to the documentation needed for the particular

claim(s). However, third-party certification cannot be carried over to other products unless the company has the same certification. NOTE: See label example Organic USDA organic regulations describe the specific standards required for a company to use the word \u201corganic\u201d or the USDA organic seal on food, feed, or fiber products. See <https://www.ams.usda.gov/services/organic-certification-and/or> <https://www.ams.usda.gov/rules-regulation/organic/labeling>. The USDA organic regulations are administered by AMS\u2019s National Organic Program (NOP) and described at 7 CFR Part 205. For animal products to be labeled as organic, livestock producers must be certified organic and any operations that subsequently handle the organic product must be certified organic (e.g., slaughter plants, meat", "16 packing facilities). Organic operations are inspected annually by USDA-accredited certifying agents. The label bearing the claim needs to include the certifying entity\u2019s name, website address, and logo, when the organization has a logo. 1. FSIS accepts current organic certificates to substantiate certain animal raising claims such as: \u201craised without antibiotics,\u201d \u201cno added hormones,\u201d \u201cvegetarian diet,\u201d \u201cno animal-by-products,\u201d \u201cNON-GMO\u201d and \u201chumanely raised\u201d with company\u2019s description and qualifier [\u201cThese are consistent with the USDA organic regulations\u201d]. 2. As referenced previously in this document, organic claims, logos and\or websites from purchased products cannot be carried over to other products unless the company has the same certification. 3. If an establishment produces meat or poultry products that qualify for an organic claim under the NOP, the establishment would not need to provide a written description of the product tracing and segregation mechanism because these activities are a condition of NOP certification. NOTE: See label example Requesting approval for the addition of new suppliers to the documentation for a product with a previously approved label bearing animal raising claims LPDS has procedures in place that allow for an establishment to add a new supplier to the documentation of a previously approved label and not have to resubmit the label for another sketch approval. For the purposes of this section, a supplier is a producer, farmer, or even another establishment that provides animals or products to another establishment to use in its products that bear the same animal raising claims. Examples would include but not limited to suppliers added for an approved product label bearing animal raising claims, meat or poultry cuts for specific breeds. Additional suppliers must be approved by LPDS and upon approval the labeling record must be updated to reflect the new supplier(s). To obtain approval, the producing establishment would need to submit a signed and dated request to LPDS by email or letter that includes the following: 1. The product name; 2. The producing establishment\u2019s name, address, and establishment number; the prior label approval number; and a copy of the previously approved label application; 3. The specific claim(s) that will be used on the product label containing source materials from the new supplier; 4. The new supplier\u2019s name, address, and one copy of any labels with the same claim(s) previously approved by LPDS associated with the supplier or documentation to support why the claim(s) also applies to the new supplier; and 5. Finally, for claims certified by a third-party, include a copy of the current certificate(s). Due to the fact that most certifications expire after one year, FSIS will consider a certificate current based on a one-year time span unless the certificate states otherwise.", "17 Once all the documentation above is evaluated, LPDS will notify the applicant in writing of its final determination. As mentioned above, this letter needs to be included as part of the

supporting documentation in the producing establishment's official labeling record. Label Example The above label contains the following types of claims: - Breed (Angus); - Diet (Grass-fed); - Living\Raising\Raising Conditions (Free-Range); - Raised Without Antibiotics \u2013 Livestock\Red Meat (No Added Antibiotics); - Raised Without Added Hormones (No Added Hormones Administered); - Source\Traceability (Source Verified and Traceable to TMB Ranch); - Third-Party Certification (LPDS True 2 Earth); and - Organic (USDA Organic)", "18 http:\askfsis.custhelp.com\ FSIS\USDA www.fsis.usda.gov 2019"]}, {"file\_name": "FSIS\_GD\_2019\_0010", "title": "FSIS Product Categorization (Import)", "num": "FSIS-GD-2019-0010", "id": "41349f1c1feb7f785d5687f2c1b12b4b243c5cbf9f25b806a974de01ebd06cf9", "corp\_us": "fsis\_guidelines", "source\_page\_url": "https:\www.fsis.usda.gov\policy\fsis-guidelines", "url": "https:\www.fsis.usda.gov\sites\default\files\media\_file\2021-05\Product-Categorization\_0.pdf", "type": "pdf", "n\_pages": 16, "word\_count": 3479, "text\_by\_page": ["FSIS Product Categorization FSIS has developed this document to assist with accurate identification of the meat, poultry, and egg products certified for export to the United States. Process Category: There are nine (9) process categories identified in 9CFR 417.2(b). Of the nine (9) listed, Slaughter is considered an internal process that occurs in establishments where the animals or birds are slaughtered. This category is not used for imported products. An additional process category that is not contained in 9CFR 417.2(b) is Egg Products. Note that FSIS has recently renamed two process categories: Raw Product -Ground and Raw Product -Not Ground are now referred to as Raw Product -Non-Intact and Raw Product -Intact, respectively. However, use of either terminology will be acceptable to FSIS. Note that official foreign inspection certificates should reflect the process category name, rather than the obsolete coding previously used by FSIS (e.g. 03B, 03C, etc.). These codes have been included in the table as some countries previously certified the process categories on the inspection certificates with this coding. Raw Product -Non-Intact: This process category applies to establishments that further process by using processing steps such as grinding, comminuting, injecting product with solutions, or mechanical tenderization by needling, cubing, pounding devices or other means of creating non-intact product. Examples of finished products in this category include raw products reconstructed into formed entrees, mechanically separated species, and advanced meat recovery product. If the establishment produces bench trim or pieces of meat produced from non-intact meat, then the bench trim or pieces are also considered non-intact. Raw Product -Intact: FSIS considers raw products to be intact unless they have undergone any of the processes associated with the Raw Product -Non-Intact process category. Thermally Processed -Commercially Sterile: This process category applies to establishments that use a thermal processing step. Thermally processed, commercially sterile finished products are products in cans or flexible containers such as pouches, or semi-rigid, as in lunch bowls. Thermally processed, commercially sterile products are addressed in 9 CFR 431. Not Heat Treated -Shelf Stable: This process category applies to establishments that further process by curing, drying, or fermenting processing step as the sole means by which product achieves food safety. Establishments in this process category may apply a low-level heat treatment as long as the heat treatment is not used as means to achieve food safety. The finished products produced under this Process Categories are shelf stable. FSIS does not require

shelf stable products to be frozen or refrigerated for food safety purposes. Heat Treated -Shelf Stable: This process category applies to establishments that further process by using a heat treatment processing step to achieve food safety in combination with curing, drying, or fermenting processing step to achieve food safety. The finished products produced under this process category are shelf stable. FSIS does not require shelf stable products to be frozen or refrigerated for food safety purposes. If the establishment produces using the processing steps applicable under this process category and the product is not shelf stable, then establishment is producing product under the process category Fully Cooked -Not Shelf Stable. Fully Cooked - Not Shelf Stable: This process category applies to establishments that further process products by using primarily a full lethality heat process step (e.g. cooking) to achieve food safety. The finished products that establishments produce under this process category are not shelf stable. FSIS requires the products to be frozen or refrigerated for food safety purposes. These products also meet the definition of Ready to Eat (RTE) as defined in 9 CFR 430.1." "Heat Treated but Not Fully Cooked -Not Shelf Stable: This process category applies to an establishment that further processes products that are (1) not ready-to-eat products (NRTE) or (2) raw otherwise processed products that are refrigerated or frozen throughout the product's shelf life. Meat and poultry products are produced using a heat process that meets one of the following criteria: a. The heat-processing step is not adequate to achieve food safety. Products may be partially cooked or heated to set batter on a raw product. b. The heat processing step applied to meat or poultry component was adequate to achieve food safety, however product is further processed, assembled, or packaged so that cooked meat or poultry products contacts nonready to-eat product ingredients. In this case, the final product is in a form that is not edible without additional preparing to achieve food safety. An example of this product is pot pie product that contains cooked chicken and raw dough. NOTE: This category may also include products that receive a full lethality treatment but there is no standard of identity defining them as fully cooked (e.g., hotdogs or barbecue) or a common or usual name that consumers understand to refer to RTE product (e.g., pates). Products with Secondary Inhibitors -Not Shelf Stable: This process category applies to establishments that further process by using a curing processing step or a processing step using other ingredients that inhibit bacterial growth. These products are generally refrigerated or frozen throughout the product's shelf life. Depending on the process and ingredients, these products may or may not meet the definition of RTE as defined in 9 CFR 430.1. Eggs\Egg Products: This process category applies to dried, pasteurized, and unpasteurized egg products. Product Category: (with Applicable Species) The Product Categories are shown in the FSIS Product Categorization table with the appropriate species indicated for each. The Species designations FSIS is using for PHIS are: for Meat: Beef, Veal, Pork, Lamb, Mutton, and Goat; for Poultry: Chicken, Turkey, Duck, Goose, Guinea, and Squab, including for Ratites: Emu, Ostrich, and Rhea; for Eggs: Chicken, Turkey, Duck, Goose and Guinea; for Siluriformes: Siluriformes -Ictaluridae (Catfish), Siluriformes \u2013 Other; and for Egg Products: Chicken, Turkey, Duck, Goose, and Guinea. For each product, the certification must indicate which species is predominant in the product to assure the appropriate regulations are applied to the product when applicable. Product Group: The product group defines the product down to a level that FSIS can program appropriate types of inspections (TOI) for examinations and laboratory sampling. While these appear to be self-explanatory, for Raw Product -Intact, Cuts are cuts of meat that are below the Primal and Subprimal level (e.g.,

food service\retail cuts such as steaks, or chops).", "The following table displays the process categories and the types of finished products that can be present in a process category.

Finished Product Types by Process Category

Process Categories	Finished Products	Raw Product
NRTE Product	RTE Products	Thermally Processed Product
(Raw Ground)	Slaughter	\u2022 Raw -Non Intact
\u2022 Raw -Intact (Raw Not Ground)	\u2022 Thermally Processed -	
Commercially Sterile	-Shelf Stable	\u2022 \u2022 HeatTreated-ShelfStable
\u2022 Fully Cooked -Not Shelf Stable	\u2022 Heat Treated but Not Fully Cooked -Not Shelf Stable	\u2022
\u2022 Product with Secondary Inhibitors -Not Shelf Stable	\u2022	\u2022
\u2022 Eggs\Egg Products	Not Applicable Ready to Eat applies to any product intended for human consumption without further preparation steps. Note: Products that appear fully cooked or are customarily consumed without further preparation, but the label does not include cooking instructions, are by default considered RTE. RTE fully cooked means that the products have been sufficiently cooked so that they are safe to eat as they are, with no further preparation required by the consumer. Note: Many of these products are customarily eaten hot, and heating instructions may be included on the label. Some frozen RTE products require reheating for palatability. These frozen products are still safe to eat without this further preparation by the consumer and are therefore still considered RTE. Some examples include: fully cooked hams, cooked beef, roast beef, pastrami, corned beef, hot dogs, meat loaves, meat and poultry salads, sliced luncheon meats, baked chicken, frozen entrees, and poultry rolls.	
Fresh or frozen entrees with fully cooked meat or poultry portions combined with fully cooked sauces, vegetables, pasta, or other ingredients	are RTE products. These products are designed to be re-heated by the consumer, and may include instructions for re-heating. Not Ready to Eat applies to products with cooking instructions or labeled with statements on the principal display panel such as \"Cook Thoroughly, Cook and Serve, Not Ready to Eat, or For Safety and Quality-follow these cooking instructions.\\" These products are considered NRTE. Certain NRTE products are required to bear safe handling instructions (SHI).", "Some NRTE finished products are heat treated but are not fully cooked. These NRTE products should have sufficient labeling information to inform the consumer that the product must be cooked for safety. This information may be contained within the product name on the principal display panel, and may contain cooking instructions that refer to cooking the product for safety rather than heating the product for best quality. The product often times may bear a safe handling instruction. Some NRTE finished products are prepared with both meat\poultry components that have received a lethality treatment in combination with non-meat\poultry components that need to receive a lethality treatment. These multi- component products, e.g., meals, dinners, and entrees, have labeling features which are conspicuous so that intended users are fully aware that the product must be cooked for safety. The principle display panel on the label defines these products, e.g., \"Cook and Serve, \"Must be thoroughly cooked,\\" \"Cook before eating\", and the product should include cooking instructions when required. Processors should refer to <a href="http://www.fsis.usda.gov/wp/cm/connect/ebb99e17-40f9-4528-ac0f-0b733fd87fd6/Resource_1.pdf?MOD=AJPERES">http://www.fsis.usda.gov/wp/cm/connect/ebb99e17-40f9-4528-ac0f-0b733fd87fd6/Resource_1.pdf?MOD=AJPERES</a> for guidance on the labeling of NRTE products.", "Raw Product -Non-Intact [HACCP] Process Category [Finished] Product Category Species Product Group Raw -Non Intact Raw ground comminuted or otherwise non-intact Siluriformes Siluriformes -Ictaluridae (Catfish), Siluriformes -Other \u2022 Ground Product \u2022 Non-Intact Cuts \u2022 Other Non-Intact Raw ground, comminuted, or Beef, Veal \u2022 Advanced

In this presentation I will first explain what equivalence is. Then I\u2019ll discuss the origin of equivalence and FSIS\u2019s requirements. Following that, I\u2019ll discuss the four (4) types of FSIS\u2019s equivalence determinations, which includes initial, ongoing, reinstatement, and individual sanitary measure, and the process steps involved for each type of equivalence"]}

determination. 2","In order to understand FSIS\u2019s equivalence determination processes, let\u2019s first start out by clarify what equivalence means. 3","Equivalence is the process of determining whether a country\u2019s food safety inspection system achieves FSIS\u2019s appropriate level of protection for public health as applied domestically in the United States (US). 4","The country\u2019s food safety inspection system is to provide standards equivalent to FSIS to ensure other non-food safety requirements are met, such as humane handling, accurate labeling, and assurance that meat, poultry, or egg products are not economically adulterated. 5","Equivalence does not mean that the country is required to develop and implement the same procedures that the US does, but rather the country must objectively demonstrate how its procedures meets the US level of protection. Countries wishing to become eligible to export meat, poultry, or egg products to the US must demonstrate that they have a regulatory food safety inspection system that is equivalent to that of the US. 6","FSIS is the US Central Competent Authority (CCA) responsible for regulating and inspecting meat, poultry, and egg products. The CCA is a country\u2019s national government authority that is responsible for ensuring the safety and truthful labeling of the food supply. FSIS implements an equivalence determination process to ensure that US treaty obligations under the World Trade Organization\u2019s (WTO) Agreement on the Application of Sanitary and Phytosanitary Measures (SPS Agreement) are met. 7","The World Trade Organization\u2019s (WTO)\u2019Agreement on the Application of Sanitary and Phytosanitary Measures (SPS Agreement) sets out the basic international rules for food safety, animal, and plant health standards. FSIS ensures during the equivalence process that SPS Agreement principals are implemented. 8","To ensure that meat, poultry, or egg products (including imported products) do not pose any public health risks to US consumers, FSIS implements the Federal Meat Inspection Act (FMIA), Poultry Products Inspection Act (PPIA), Egg Products Inspection Act (EPIA), Humane Methods of Slaughter Act (HMSA), and regulations under Title 9 Code of Federal Regulations (CFR) Parts 300-590. FSIS ensures that a country\u2019s food safety inspection system addresses FSIS\u2019s food safety regulatory-based objectives. Food safety regulatory-based objectives are food safety goals for preventing the occurrence of an identified food safety hazard. The criteria by which FSIS assesses the equivalence of a country\u2019s food safety inspection system can be found under Title 9 CFR \u00a77327.2 (for meat products), \u00a77557.2 (for fish of the order Siluriformes products), \u00a77381.196 (for poultry products), and \u00a77590.910 (for egg products). 9","Determining equivalence of a country\u2019s food safety inspection system is important because it protects public health and facilitates trade. An equivalence determination of an exporting country\u2019s regulatory food safety inspection system for meat, poultry, or egg products is a prerequisite for trade for the United States Department of Agriculture\u2019s (USDA) FSIS. 10","Now that we have a better understanding of what equivalence is and FSIS\u2019s statutory and regulatory requirements associated with equivalence determinations, let\u2019s discuss FSIS\u2019s different equivalence determinations and the process steps. 11","There are four (4) types of equivalence determinations: (1) Initial Equivalence, (2) Ongoing Equivalence Verification, (3) Reinstatement of Equivalence, and (4) Individual Sanitary Measure. 12","Initial Equivalence Process is undertaken when countries want to export meat, poultry, or egg products to the US for the first time. FSIS evaluates a country\u2019s food safety inspection system to make an initial equivalence determination before the country can export products to the US. This process is for

countries that are not listed in the CFR as eligible to export meat, poultry, or egg products. 1. To start the initial equivalence process, countries are to have their CCA contact FSIS\u2019s Office of International Coordination (OIC) by sending a formal written request to start the initial equivalence process. 2. In response to a country\u2019s request, FSIS will send the country a packet of information that includes guidance and a Self-Reporting Tool (SRT). We will discuss what the SRT is on the next slide. 3. After FSIS receives an SRT with all referenced supporting documentation, FSIS reviews and decides whether the country\u2019s food regulatory system meets all US import requirements in an equivalent manner and cumulatively provides the level of public health protection as that attained domestically. 4. An on-site verification audit is an audit of the country\u2019s food safety inspection system with the goal of verifying, through objective evidence, that the country\u2019s inspection system has an equivalent level of public health protection as applied domestically in the US. 13", "5. Based on the outcome of FSIS\u2019s SRT and supporting documentation review and the on-site audit, FSIS initiates rulemaking to propose that the country be listed in the CFR as eligible to export meat, poultry, or egg products to the US. 6. FSIS analyzes any received comments and publishes a final rule to list the country in the CFR as eligible to export meat, poultry, or egg products to the US. FSIS sends the country a notification letter about the published rule. The letter includes instructions about exporting meat, poultry, or egg products to the US. 13", "The SRT is a questionnaire that provides an organized means for the country\u2019s government to demonstrate that its inspection system achieves an equivalent level of protection as applied domestically in the US. The SRT is arranged into six (6) components: 1. Government Oversight (e.g., Organization and Administration) 2. Government Statutory Authority and Food Safety and Other Consumer Protection Regulations (e.g., Inspection System Operation, Product Standards and Labeling, and Humane Handling) 3. Government Sanitation 4. Government Hazard Analysis and Critical Control Point (HACCP) System 5. Government Chemical Residues Testing Programs 6. Government Microbiological Testing Programs Please refer to the SRT and the presentation on How to Complete and Submit the SRT Using the Public Health Information System (PHIS) for additional information on how a country should categorize its food safety inspection system, respond to the SRT, and submit a completed SRT to FSIS for review. 14", "An on-site verification audit is an audit of the country\u2019s food safety inspection system with the goal of verifying, through objective evidence, that the country\u2019s inspection system has an equivalent level of public health protection as applied domestically in the US. If FSIS determines that a country\u2019s food safety inspection system is tentatively equivalent based on the SRT document review process, OIC will work with the country\u2019s CCA to arrange an on-site verification audit of the country\u2019s food safety inspection system. Initial equivalence audits are conducted FSIS International Auditors. The audit scope includes visual observations of all aspects of the country\u2019s food safety inspection system. 15", "During the on-site audit, International Auditors verify that the CCA implements, monitors, and verifies all of the procedures in the country\u2019s food safety inspection system. Typically, International Auditors will need to visit multiple sites that may include the following: \u2022 Central, regional, and local government offices; \u2022 Exporting establishments (slaughter and processing establishments) and warehouses (including cold storage); and \u2022 Laboratories. After the on-site audit, FSIS sends a draft audit report to the country applying for equivalence for the country\u2019s review and comment. FSIS then takes the country\u2019s comments

into account and generates the final audit report. 16","In order for FSIS to make an initial equivalence determination, the CCA should show through documentation, which includes SRT responses and supporting documentation, that the design of its food safety inspection system achieves an equivalent level of public health protection. Once the CCA can show through documentation that its food safety inspection system is equivalent, the CCA is to show FSIS that it can implement the inspection system as documented in the submitted SRT responses and supporting documentation. Equivalent documentation and acceptable audit results will support FSIS to initiate rulemaking by publishing a proposed rule in a Federal Register. 17","Based on the outcome of FSIS\u2019s SRT and supporting documentation review and the on-site audit, FSIS initiates rulemaking to propose that the country be listed in the CFR as eligible to export meat, poultry, or egg products to the US. To initiate rulemaking, the country will need to provide 5 years of projected economic analysis information. Upon publication, the public can submit comments (generally up to 60 days after publication) to FSIS about the proposed rule. FSIS analyzes any received comments and publishes a final rule to list the country in the CFR as eligible to export meat, poultry, or egg products to the US. FSIS sends the country a letter notifying it of the published rule. After the rule becomes effective, the country then certifies establishments as being eligible to export meat, poultry, or egg products to the US. After a country has compiled a list of eligible certified establishments, the country sends the completed list to OIC. A certified establishment is an establishment that the CCA determines as meeting US requirements and, therefore, eligible to export meat, poultry, or egg products to the US. Additionally, countries are to submit to OIC a sample of the health certificate they propose to use for exported meat, poultry, or egg product shipments to the US. Each eligible country\u2019s CCA is responsible for the certification of shipments of meat, poultry, or egg products to the US. Please refer to Title 9 CFR \u00a7327.4 (for meat), \u00a7557.4 (for fish of the order Siluriformes), \u00a7381.197 (for 18","poultry), and \u00a7590.915 (for egg products). 18","It is important to note that FSIS only determines whether a country\u2019s meat, poultry, or egg products food safety inspection system is equivalent. Countries should be aware that animal diseases are regulated by the USDA\u2019s Animal and Plant Health Inspection Service (APHIS) (Title 9 CFR Parts 92 through 95), and a country\u2019s animal disease status can impact what products the country can export to the US. For a list of USDA-recognized animal health status of countries, please visit APHIS\u2019s Animal Disease Status webpage ([https://www.aphis.usda.gov/aphis/ourfocus/animalhealth/animal-and-animalproduct-import-information/ct\\_animal\\_disease\\_status](https://www.aphis.usda.gov/aphis/ourfocus/animalhealth/animal-and-animalproduct-import-information/ct_animal_disease_status)). 19","Countries are to contact OIC for: 1. All questions and requests for technical assistance, 2. To submit formal equivalence requests, 3. To submit a paper copy of an SRT and supporting documentation for review, or 4. To notify FSIS that an SRT was submitted in PHIS. Please submit all written equivalence requests to OIC by e-mail (preferred), mail, or fax. 20","Ongoing equivalence is applicable to countries that are listed in the CFR as eligible to export to the US and are actively shipping meat, poultry, or egg products to the US. FSIS will continuously evaluate and verify the equivalence of an exporting country\u2019s food safety inspection system through a three (3) part process: (1) on-site audits, (2) document reviews, and (3) point-of-entry (POE) reinspection of meat, poultry, and egg products. FSIS will periodically conduct an on-site audit of every eligible country\u2019s food safety inspection system. These audits will be performed by FSIS International Auditors and are similar to the on-site verification audits that FSIS does as part of

the initial equivalence process. Countries are to submit the following for review at least annually by May 18th:

1. Either (1) updated SRT responses, or (2) communicate to FSIS that the Central Competent Authority (CCA) has verified its SRT responses, as recorded in FSIS's Public Health Information System (PHIS) (i.e., by reviewing the SRT electronically in PHIS) or by mailed hard copy of the version of SRT responses FSIS has entered for the CCA, are accurate and complete.
2. An up-to-date list of all certified establishments eligible to export meat, poultry, or egg products to the US.
3. An updated government residue control program, including the previous year's residue test results and reactions to residue findings.
4. Updated government microbiological sampling and testing programs, including the previous year's test results and reactions to (A) indicator organism results for intestinal or fecal contamination; (B) *Salmonella* and *Campylobacter* results for raw meat and poultry products; (C) *Listeria monocytogenes*, *Salmonella*, or other pathogens of public health concern in ready-to-eat (RTE) meat and poultry products and all lots of pasteurized egg products; and (D) shiga toxin-producing *Escherichia coli* (STEC) in raw beef products.

All imported shipments of meat, poultry, and egg products that enter the US are presented to FSIS for reinspection. If a POE violation is identified, FSIS notifies the countries, and requests and reviews corrective action responses.

"Countries wishing to reinstate previous equivalence determinations to start exporting meat, poultry, or egg products to the US again are to send a formal written request to OIC. Reinstatement of equivalence is only applicable to countries who are listed in the CFR as eligible to export to the US, but have not shipped meat, poultry, or egg products to the US for an extended period of time. A possible reason for a country to request a reinstatement of equivalence determination includes the lifting of a trade ban after an extended period of time due to a change in animal disease status allowing the export of certain animal products to the US. A reinstatement of equivalence process follows the same process as the initial equivalence process, except that the country may be subjected to a verification audit, and will not be subjected to the rulemaking steps. The rulemaking steps are not applicable for a reinstatement of equivalence determination because the country's food safety inspection system has already been determined to be equivalent. After FSIS completes its document review and, as needed, an on-site verification audit, OIC will notify the country of FSIS's decision through a formal written letter. The letter will discuss FSIS's basis for its decision to reinstate equivalence. If FSIS does not perform an audit as part of the reinstatement of equivalence process, then FSIS will verify the reinstated process during the next scheduled audit."

"Countries wishing to change a procedure (sanitary measure) that the US has previously determined to be equivalent in their food safety inspection system are to send a formal written request to OIC. An individual sanitary measure is only applicable to countries who are listed in the CFR as eligible to export to the US, but want to change a previously determined equivalent procedure in their food safety inspection system. An example of an individual sanitary measure equivalence determination request is when a country wants to change its postmortem inspection procedures for livestock from traditional (hands-on) inspection to visual assessment. An eligible country is to request an individual sanitary measure equivalence determination before the country implements the new procedure on products destined for export to the US. Countries are to submit a formal written request for an individual sanitary measure to FSIS's OIC. If a country does not notify FSIS of changes in its food safety procedures, a possible disruption of trade could result. FSIS will evaluate a request for an

individual sanitary measure equivalence determination to ensure that the new procedure: \u2022 Is equivalent to FSIS\u2019s relevant food safety regulatory objective-based criteria, and \u2022 Achieves an appropriate level of protection from identified food safety hazards. Countries that request an individual sanitary measure will need to update their SRT and submit supporting documentation to FSIS for review. The submitted 23","documentation should demonstrate that the measure provides an equivalent level of public health protection. After FSIS completes its review, OIC will notify the country of FSIS\u2019s decision through a formal written letter. The letter will discuss FSIS\u2019s basis for its decision to either accept or reject the proposed individual sanitary measure. If FSIS accepts the individual sanitary measure, FSIS will verify the application of the individual sanitary measure during the next scheduled on-site verification audit. 23","FSIS has a food safety objective-based criterion that requires the CCA to ensure that raw beef products are free of STEC at the end of the production process. In the US, beef slaughter and processing establishments use a combination of antimicrobial treatments and sanitary dressing procedures to control STEC. 24","However, other countries prohibit the use of antimicrobial treatments and have submitted requirements that raw beef establishments are to implement robust sanitary dressing procedures with additional controls and government verification procedures to prevent STEC. In this situation, the CCA has verification procedures (including rigorous microbial sampling) that demonstrate sanitary dressing procedures ensure that raw beef products are free of STEC at the end of the production process. Additionally, the CCA\u2019s controls include a focus on carcasses as well as other conditions (high event periods) and classes of raw products that collectively increase the likelihood of detecting STEC if present. Based upon the evaluation of the CCA\u2019s verification procedures, controls, and receipt and evaluation of ongoing microbial results from the CCA, FSIS has determined this approach to be equivalent because the CCA demonstrates that it meets the food safety criterion. 25","For all questions, including technical and equivalence questions, please contact OIC through methods listed above. 26","27

27"]},{"file\_name":"FSIS\_GD\_2019\_0012","title":"How to Complete and Submit the SRT Using the PHIS (Presentation)","num":"FSIS-GD-2019-0012","id":"c7e8ec25c61e68a51d1b199b716dcea67f0223a45f9c2cbfcf771982d99393b7","corp\_us":"fsis\_guidelines","source\_page\_url":"https://www.fsis.usda.gov/policy/fsis-guidelines","url":"https://www.fsis.usda.gov/sites/default/files/import/Submit-SRT-Using-PHIS-

PPT.pdf","type":"pdf","n\_pages":70,"word\_count":4950,"text\_by\_page":["1","Thank you for your interest in learning how to complete the Self\u2010Reporting Tool, or SRT, for initial, reinstatement, and ongoing equivalence. In this presentation I will first explain what the SRT is. Then I\u2019ll discuss recent improvements to the SRT. I\u2019ll next discuss how to complete and update the SRT. Following that, I\u2019ll discuss the Food Safety and Inspection Service\u2019s (FSIS) procedures for translating submitted SRT responses, programs, or supporting documentation into English and how it affects the review time. Next, I\u2019ll walk through how to become e\u2010authenticated and gain access to the Public Health Information System (PHIS). Finally, I\u2019ll show you how to submit the SRT through PHIS. 2","For countries that have not exported meat, poultry, or egg products to the United States (US) before, you are probably wondering what the SRT is. 3","The SRT is a questionnaire that provides an organized means for the country\u2019s government, or Central Competent

Authority (CCA), to demonstrate that its inspection system achieves an equivalent level of public health protection as applied domestically in the US. The CCA is the country's national government authority that is responsible for ensuring the safety and truthful labeling of the food supply. The CCA is expected to answer all component questions in the SRT in order for an effective determination of equivalence.

4", "The SRT is arranged into six components that define a food safety inspection system. The six (6) defined components are:

1. Government Oversight (e.g., Organization and Administration)
2. Government Statutory Authority and Food Safety and Other Consumer Protection Regulations (e.g., Inspection System Operation, Product Standards and Labeling, and Humane Handling)
3. Government Sanitation
4. Government Hazard Analysis and Critical Control Point (HACCP) System
5. Government Chemical Residues Testing Programs
6. Government Microbiological Testing Programs

The questions under these six components are called component questions. The component questions are the food safety objective-based criteria that FSIS uses to determine equivalence in the form of a question. The food safety objective-based criteria are based off of FSIS' laws and regulations. This includes FSIS' Federal Meat Inspection Act (FMIA), Poultry Products Inspection Act (PPIA), Egg Products Inspection Act (EPIA), Humane Methods of Slaughter Act (HSMA), and Title 9 Code of Federal Regulations (CFR) Parts 300 through 590. The CCA is expected to answer all component questions in the SRT in order for effective determination of equivalence.

5", "6", "Countries wishing to export meat, poultry, or egg products are to send a formal written request to FSIS' Office of International Coordination (OIC) to start the equivalence determination process. FSIS will then provide the country with a packet of information that includes a copy of the SRT and guidance materials to assist you with the equivalence process. Countries wishing to reinstate previous equivalence determinations, or that want to change a procedure that the US has previously determined to be equivalent are to send a formal written request to OIC. Written requests need to include the type of equivalence determination process (for example, initial or reinstatement), as well as the specific commodity (or commodities) the equivalence request is for. For example, reinstatement of equivalence for raw beef, or initial equivalence for heat treated and thermally processed poultry.

7", "As a result of helpful feedback from CCAs, FSIS has significantly improved the current version of the SRT.

8", "Specifically, FSIS significantly reduced the number of questions by revising the questions to focus on the food safety objective-based criteria to be achieved. Food safety objective-based criteria are the standards that FSIS uses to determine whether the country's food safety inspection system is equivalent. The component questions, that is, the questions listed under the six components in the SRT, are the food safety objective-based criteria that FSIS uses to determine equivalence in the form of a question. These changes are designed to help countries better understand the food safety objective-based criteria that FSIS uses to evaluate whether the country's food safety inspection system is equivalent. These changes have also greatly reduced redundancy and make the questions more understandable. The revised SRT is available in PHIS for countries to use. We will discuss later in this presentation how to gain access to PHIS, and the steps on how to complete and submit the SRT in PHIS.

9", "So, you have sent a formal request to FSIS' Office of International Coordination, and received a copy of the SRT to complete. How do you respond to the SRT?

10", "The questions under the six components are called component questions. The CCA is expected to answer all component questions in the SRT in order for an

effective determination of equivalence. The CCA should provide complete responses to SRT questions. Complete responses include a short narrative, accompanied by supporting documentation, to characterize how a country's food safety inspection system is implemented. Responses should include references to where in the supporting documentation the answer to the question is found. For example, answers should include the page number, section number, or chapter from the relevant supporting documentation.

11", "The CCA should submit all supporting documentation concerning its food safety inspection system in the SRT. The following list identifies types of supporting documentation that the CCA should provide in the SRT to show how its food safety inspection system is equivalent to the US domestic food safety inspection system.

12", "To submit the SRT with all applicable programs and supporting documentation, the CCA can either use the Microsoft Word version of the SRT or upload the information into the webbased PHIS. FSIS encourages countries to submit the information through PHIS by inserting the responses directly. If the Microsoft Word version is submitted to FSIS, FSIS then extracts the information and places it into an SRT in PHIS. Consequently, this extra handling may contribute to added error or missing information. In addition, to extract and upload the SRT responses and supporting documentation into PHIS, will delay the review process up to a couple of weeks if submitted in English. The benefits for using PHIS to submit the information includes an expedited SRT review, transparency, and security. To ensure an expedited review of a submitted SRT, particularly an SRT submitted in PHIS, FSIS encourages countries to submit SRT responses and supporting documentation in English.

13", "FSIS acknowledges that most countries' native language is not English. However, to expedite the equivalence review process, FSIS encourages countries to submit SRT responses and supporting documentation in English through PHIS. If you submit an SRT and supporting documentation in a language in other than English, FSIS will have to have the information translated and then have the country verify that the translations are accurate. This can result in significant delays and possible errors.

14", "The following steps describe the process FSIS follows to ensure that translations are accurate.

1. First, the CCA submits the SRT and documents to FSIS in a language other than English.
2. Next, FSIS sends the SRT and documents for translation into English.
3. Upon receiving the translated SRT and documents, FSIS inserts the English translated SRT responses into the SRT in PHIS.
4. Next, FSIS provides the CCA the opportunity to verify the accuracy of the English translated SRT responses and documents.
5. Finally, the CCA responds to FSIS concerning the accuracy of the translated SRT and documents. If the CCA provides corrections to the translated SRT in a language other than English, FSIS will send the corrections for translation, and the process will start over until the CCA agrees with the translations.

FSIS maintains all countries SRT responses and submitted supporting documentation in PHIS. Through PHIS the CCA will have the opportunity to verify that the translated responses are accurately captured by FSIS in PHIS. For countries that submitted paper SRT

15", "responses, the CCA will be provided an opportunity to verify a paper copy of the English translated SRT responses entered into PHIS. Note that by not communicating the SRT responses in English and by using a paper copy rather than PHIS for inputting SRT information by the CCA, the equivalence review process could be delayed by weeks and possibly months. Importantly, regardless of how the CCA manages the SRT, FSIS relies upon the PHIS English version of the SRT responses when making equivalence decisions. Countries are encouraged to gain access to PHIS in order to ensure completeness of documentation of the SRT.

15","I\u2019ll next discuss how to become e\u2019authenticated and how to access PHIS which is available 24\7. As I said earlier, FSIS recommends that countries enter their SRT responses and upload documentation into PHIS to expedite the review process. However, even if countries do not enter their SRT responses into PHIS, FSIS relies upon the PHIS SRT responses for its equivalence evaluation. Thus, countries can view the information in PHIS 24\7. 16","The benefits for using PHIS include an expedited SRT review, transparency, and security. Countries that use PHIS to submit their SRT only need to review and affirm SRT responses or revise certain questions to reflect changes in their inspection system in order meet the annual deadline of May 18th to update the SRT. Also, participating countries will be able to log into PHIS at any time to view their SRT and its status. Please refer to the Federal Register for more information about country access to PHIS

(<http://www.fsis.usda.gov/wps/wcm/connect/3d648d9c\u20104498\u201049ae\u20108a958adc4526deff/2014\u20100039.pdf?MOD=AJPERES>). 17","Countries that do not already have access to PHIS and level 2 eAuthentication credentialing need to complete the following steps in order to start using PHIS to complete the SRT. It is important to understand that the level 2 eAuthentication credentialing and PHIS enrollment are two separate processes. It is important to note that when the designated CCA official becomes level 2 eAuthentication credentialed, the PHIS enrollment process is not automatically initiated. As these processes are independent from one another, it will take time to complete both of these processes. To start the level 2 eAuthentication credentialing process, a country first needs to identify a designated CCA official. This identified official will be responsible for entering the SRT responses and uploading supporting documents into PHIS. This official is responsible for first obtaining level 2 eAuthentication credentials, and then requesting to be enrolled in PHIS to complete the SRT.

18","To begin the process for obtaining level 2 eAuthentication credentialing, the country\u2019s designated CCA official first needs to complete the registration form at <http://1.usa.gov/1rbeFcL>. After completing the form, the designated CCA official will receive a confirmation e\u2010mail. Typically, this happens within an hour after submitting a complete form. The official MUST respond to the e\u2010mail within 7 days of receiving the confirmation e\u2010mail. The designated CCA official will be asked to create a username and password. It is important to remember this username and password in order to log into PHIS. 19","Once your designated CCA official receives a confirmation e\u2010mail and has responded to the confirmation e\u2010mail, please contact Ms. Monica Marcelli with the Office of Policy and Program Development at [monica.marcelli@fsis.usda.gov](mailto:monica.marcelli@fsis.usda.gov) or 1 (202) 720\u20100473. Ms. Marcelli will help the designated CCA official to schedule the appointment with the LRA to verify his or her government issued photo identification. If the designated CCA official is based at an embassy in Washington DC, or visiting Washington DC, he or she can meet with the LRA at the United States Department of Agriculture building to complete the eAuthentication credentialing process. If the designated CCA official is not in the US, FSIS can make arrangements to complete the credentialing process while in country. If your designated CCA official does not receive a confirmation e\u2010mail within 24 hours after submitting the complete registration form, please contact Ms. Marcelli. 20","Once your designated CCA official receives an e\u2010mail confirming his or her level 2 eAuthentication credentials, he or she is now able to enroll in PHIS. To begin the PHIS enrollment process, open a web browser and go to <https://phis.fsis.usda.gov>. The eAuthentication login page will appear. Enter your level 2

eAuthentication username and password that the designated CCA official created while completing the level 2 eAuthentication form. 21", "On the Welcome to the FSIS Enrollment Application page, click Submit Enrollment Request. 22", "On the FSIS Enrollment Request Wizard (Step 1) page, click Next. 23", "On the FSIS Enrollment Request Wizard (Step 2) page, for the Account Type field, select Foreign Country from the drop\u2010down list and click Next. 24", "On the FSIS Enrollment Request Wizard (Step 3) page, for the Role field, select Central Competent Authority from the drop\u2010down list and click Next. 25", "On the FSIS Enrollment Request Wizard (Step 4) page, for the Country field, select your country from the drop\u2010down list and click Next. 26", "On the FSIS Enrollment Request Wizard (Step 5) page, complete any of the optional fields and click Next. 27", "On the FSIS Enrollment Request Wizard (Step 6) page, for the Comments field, type any additional information and click Next. 28", "Once you have completed the Enrollment Request Wizard, steps 1 through 6, you are taken to an Enrollment Request Summary page. Review the information. If you need to edit the information, click Previous until you get to the desired page and edit the information. Otherwise, click Finish and then click Logout eAuth. After you have submitted your enrollment request for PHIS, it will be reviewed by FSIS. You will receive a confirmation e\u2010mail once your request has been approved. This typically happens within an hour. Upon receiving your confirmation e\u2010mail, you can log in and begin using PHIS at https:\u2010\phis.fsis.usda.gov. If you do not receive a confirmation e\u2010mail 24 hours after submitting your request, please contact Ms. Marcelli for assistance. 29", "Please check junk e\u2010mail for confirmation e\u2010mails regarding level 2 eAuthentication credentialing and PHIS enrollment. Log in to PHIS at least every 60 days to prevent your account from being disabled. If your designated CCA official\u2019s PHIS account becomes disabled, he or she must make sure that his or her level 2 eAuthentication password is up\u2010to\u2010date, and then contact Ms. Marcelli for further assistance. For designated CCA officials that are enrolled in PHIS, FSIS will send reminder e\u2010mails to log into PHIS. For security reasons, eAuthentication will occasionally prompt you to change your password. If it is time to change your password, the system will prompt you to change your password. Failure to log into PHIS at least annually may result in loss of level 2 eAuthentication credentials. If the designated CCA official loses their level 2 eAuthentication credentials, they will need to complete the level 2 eAuthentication registration process again. If the designated CCA official is not able to log into PHIS because he or she has locked the level 2 eAuthentication account by trying to enter his or her password too many times, please contact the eAuthentication Help Desk at 1\u2010800\u2010457\u20103642, and select Option 1 or email eAuthHelpDesk@ftc.usda.gov. Your designated official may be prompted to answer security questions that he or she set up while completing the eAuthentication registration form. 30", "Lastly, the USDA does not permit sharing accounts or passwords. 30", "Now that you (meaning the designated CCA official) have successfully received level 2 eAuthentication credentialing and are enrolled in PHIS, you can now log into PHIS and start to complete the SRT. 31", "To log into PHIS, open a web browser and go to https:\u2010\phis.fsis.usda.gov. Log into PHIS with your Level 2 eAuthentication user ID and password that you created while completing the level 2 eAuthentication registration form. 32", "Once you\u2019re logged into PHIS, the first page you see is the Homepage. I\u2019ll refer to this as your Dashboard. 33", "Your dashboard contains a menu on the left side of the page and status notifications in the center. All designated officials are to have a PHIS user role of a Central Competent Authority. My

Dashboard displays a history of all SRT Notifications for initial, or ongoing SRTs. PHIS tracks the status of each country's SRT at the following points: Sent Request FSIS has created a new version of an SRT for a country, but you have not made any edits yet.

With Country You have opened the SRT and answered at least one question or uploaded at least one document. Submitted You have clicked Submit, but FSIS has not started the review process. You can continue to edit your SRT or upload additional documents during this phase. Under Review FSIS has started reviewing the SRT. You can continue to edit your SRT or upload additional documents during this phase.

Under Review Locked FSIS is reviewing the SRT and has locked the SRT. When an SRT is locked, you cannot make any changes to the SRT. Archived FSIS has completed its review of the SRT and has archived the SRT. After an SRT is archived, you can no longer make any changes to the SRT. All new status notifications are in bold. Once you have read a notification, you can mark it with a check mark. At that point, the status notification will no longer be in bold, so you can differentiate between read and unread notifications.

Notifications appear on your dashboard for 180 days before they are removed. NOTE: Blurred items on example screen shots are done to protect private information and will not appear when you view PHIS. Next I will discuss how to respond to the SRT questions using PHIS. Once FSIS receives a country's formal written initial equivalence request, an SRT will be generated in PHIS. FSIS will notify the country after the SRT has been created in PHIS. Countries that already have equivalence for a specific commodity and are either wishing to update their SRT information or requesting initial equivalence for another commodity are to verify that the responses and the selected supporting documents in PHIS for the specific SRT questions are correct. If the responses or supporting documents no longer reflect the country's current food safety inspection system practices, then the country needs to update the responses and supporting documents. To answer SRT questions, from the left menu, select SRT Survey. Clicking SRT Survey from your Dashboard (Homepage), you are brought to the SRT Survey page. Select the info icon for each SRT to add commodity specific information. Select the view icon for each SRT to complete or make changes to the SRT questions. When the info icon is selected, the SRT Information window appears. Here you are to provide information related to the products and process categories relevant to the selected SRT. To begin, select products to be exported and select process categories applicable to the SRT and add Additional Product Description, if necessary. For more information about the process categories and types of meat, poultry, or egg products that would fall under each process category, please review the Product Categorization guide which can be found on FSIS' website at

<http://www.fsis.usda.gov/wps/wcm/connect/abbf595d/u20107fc7/u20104170b7be/u201037f812882388/Product/u2010Categorization.pdf?MOD=AJPERES>. If information needs to be added or changed, do so and click Save. If you do not need to make any changes, click the X button in the top right corner and go to the next step. Clicking Save brings you back to the SRT Survey page. NOTE: The options on this page vary based on the selected inspection system (meat, poultry, or egg products). When you select the view icon for an SRT, the SRT Survey Details page appears. The SRT Survey Details page is a table of contents for the SRT. Expand the survey tree until you find the question you want to answer. The survey tree is organized by the Equivalence Component Level (Government Oversight, Government Statutory

Authority and Food Safety and Other Consumer Protection Regulations, Government Sanitation, Government Hazard Analysis and Critical Control Point (HACCP) Systems, Government Chemical Residues Testing Programs, and Government Microbiological Testing Programs). Within each component is the Equivalence Criteria Level that contains instructions on whether the SRT questions within that component are required or voluntary and the SRT Question Level. The SRT Question Level includes the questions that contain the criteria FSIS uses to evaluate the equivalence of a country\u2019s SRT response. Pictured here is an example of an expanded survey tree with all the levels expanded and the questions visible. Answered SRT questions will display a green checked circle next to Select in front of the question. Click Select next to the SRT question that you want to answer, review, or update.

40", "Scroll down to the Answer section and answer the question. NOTE: The system is only able to save responses in languages with a letter based alphabet. At this time, the system is not able to save responses in languages that use a symbol\u2010based script. To respond to an SRT question in a language other than English, you need to reference a word or pdf document. I will discuss later how to upload and reference documentation. If you intend to reference a document that contains your SRT question response, please type in the textbox in English \u201cSee attached response.\u201d 41", "There are two categories of questions: 1. Required questions are marked with a red asterisk (\*). If left unanswered, the system will not go to the next page until you answer all the required questions on the page. 2. Level of Advancement (LOA) are optional questions and are marked with the phrase \u201cThis is a scoreable question. It is an optional question. Select all that apply.\u201d Although these LOA questions are voluntary, a complete response by the CCA to these questions provides FSIS with more context as to how the design of the country\u2019s inspection system functions beyond the minimum expectations to ensure food safety. 42", "If you try to move onto the next page in the SRT without answering all required SRT questions, an error message appears. 43", "To return to a specific question at a later time, select the Mark for Review checkbox. For required questions, Mark for Review must have something entered into the text box in order to move to the next page of the SRT. See example placeholder. If you want to jump to the top of the page, select \u2191Top. 44", "At the top of each SRT questionnaire page is the following: Questionnaire \u2013the SRT Questionnaire version. Document \u2013a system generated document title. Status \u2013a progress tracker that identifies the percentage of SRT questions that have been responded to. Started on \u2013the date when the SRT was started (meaning when FSIS assigned the SRT to the country). Completed on \u2013the date when the SRT was completed (meaning submitted in PHIS). 45", "Once you are in the SRT survey, there are several different ways to navigate through the SRT survey. At the bottom of each SRT survey page, the following navigation options appear. Click Next to go the next page of the SRT questionnaire. Clicking Next moves you to the next page in the survey and saves your answers on the current page. Click Previous to move to the previous page. Click the blue arrows to go to either the very first page, or the last page of the SRT with unanswered SRT questions. Type in a page number in the designated Page No. box, then click Go to jump to a specific page in the SRT questionnaire. Click the pdf Reports symbol to view a pdf copy of the SRT questionnaire and the populated responses to each SRT question that you have completed thus far. Click Cancel, then SRT Import on the left side to return to the FSIS equivalence component and question survey tree. When you are ready to exit, click Save & Close to save your SRT question responses and return to the

Home page. 46", "If you clicked the pdf Reports symbol to view a pdf copy of the SRT questionnaire, this page appears. To return to the SRT Questionnaire, click Go Back to Questionnaire at the bottom left corner of the page. 47", "When you click Cancel or Submit your SRT questionnaire, this page appears. To return to the SRT questionnaire that you were working on, click Requested Questionnaire. To view and open \u201cin\u2010progress\u201d SRT questionnaires (meaning SRT questionnaires that have not been submitted for review), click My Questionnaires. To return to the SRT questionnaire equivalence component and question survey tree that you were currently working on, click SRT Import. To return to your homepage, click on FSIS Dashboard. All in\u2010progress SRT questionnaires are listed in the center of your screen under My InProgress Questionnaires. To access the first page of an In\u2010Progress SRT questionnaire, select Open on the right hand side. 48", "A complete response to an SRT question should reference programs and supporting documentation. If a country does not provide all relevant programs and supporting documentation in its SRT submission, the review process takes longer. To expedite the review process, it is important that the country upload all programs and supporting documentation into PHIS and reference the supporting documentation as part of its answer to the relevant SRT question. The following steps demonstrate how to upload and reference programs and supporting documentation.

49", "You\u2019ll first need to upload programs and supporting documentation in order to be able to reference them as part of your answer to an SRT question. To upload programs and supporting documentation, select Documents located on the left side on your dashboard.

50", "This brings you to the Country Documents page. To add a document, preferably in Microsoft Word, Microsoft Excel, or pdf, click Add Attachment. From this page, you can also download, view, or delete listed documents on the Country Documents page by selecting either the download icon or trash can icon next to the document. NOTE: Example screen shots are intentionally blurred to protect private information. Screens will not appear blurry when you view PHIS. 51", "To add a document, scroll to the bottom of the page. In the File Name field, click Browse. Locate the file you want to upload and click Open. For the Document Title field, type a meaningful title. Click Upload. It may take a few minutes for the document to upload. The page refreshes with the newly attached file in the grid. If the document does not appear after the page finishes loading, click Refresh and the document should appear. If a document does not appear after clicking Upload, or you receive an error message, the file may be too large. Therefore, you may need to break up files over 5 MB into smaller files to be able to upload them into PHIS. 52", "After you have uploaded all documents, click on SRT Survey on the left to return to the SRT. You\u2019re now ready for the second step, add a reference to the supporting documentation. 53", "This brings you to the SRT Survey page. Select the View icon next to the SRT that you want to add, update, or remove references to programs and supporting documentation. 54", "Clicking the View icon brings you to the SRT Survey Details page. Expand the survey tree until you find the question you want to add, update, or remove referenced programs and supporting documentation. Then click Select to go to that specific question in the SRT. 55", "After your question loads, click Add Reference below the answer field. A grid appears with a list of all uploaded programs and supporting documents. 56", "Locate the document that you wish to reference. 57", "Next, if applicable, select a Category that best describes the associated document. NOTE: Countries can only add categories to documents that are referenced to an SRT question. 58", "After clicking Select, the grid disappears and the

Questionnaire page refreshes with the document appearing in the reference grid. The bookmark name for a selected bookmark appears after the file name. The category, if selected, appears in parentheses to the right of the file name in the grid. To delete a referenced document, click the red X next to the document from this grid. This does not remove the document from PHIS. This action only deletes the reference between the document and that specific question. 59","After you have responded to each question and referenced all relevant programs and supporting documentation in the SRT, you are now ready to submit the SRT to FSIS for review. 60","Navigate to the last page of questions in the SRT questionnaire and click Next. If you have marked questions for review, PHIS displays the Questions Marked for Review page with a grid of all the questions that were marked for review. If you do not have any questions marked for review, proceed. 61","To review a question, click Review in the far right column. PHIS opens the SRT on the page that contains the question under review. Review your answer and make any necessary changes. Then uncheck the Mark for Review checkbox and click Next. PHIS opens the SRT at the next question that was marked for review. Repeat these steps until all checkmarks have been removed. If you do not wish to review checked Mark for Review questions, then click Remove All Marks on this page. After you have addressed all questions marked for review, click Continue. 62","On the Submit Questionnaire page, click Submit. 63","Congratulations! You have successfully submitted the SRT in PHIS. At this point, the SRT is submitted to FSIS for review. Please notify OIC after you have submitted the SRT. You can monitor the status notification changes made to your SRT during the review process on your dashboard. Clicking Submit brings you to the My Questionnaires page. 64","65","Countries are to contact FSIS\u2019s Office of International Coordination for: 1. All questions and requests for technical assistance, 2. To submit formal equivalence requests, 3. To submit a paper copy of an SRT and supporting documentation for review, or 4. To notify FSIS that an SRT was submitted in PHIS. 66","67"]},{"file\_name":"FSIS\_GD\_2019\_0014","title":"FSIS Guidance for Suggested Reporting Tables of the Government Chemical Residue Control Program","num":"FSIS-GD-2019-0014","id":"09cdcb2ad3ed72006d7cda8cdc2c7e4c66eec6f842f2a38b5a968a9a6ba54344","corpus":"fsis\_guidelines","source\_page\_url":"https://www.fsis.usda.gov/policy/fsis-guidelines","url":"https://www.fsis.usda.gov/sites/default/files/import/Suggested-Reporting-Tables-Government-Chemical-Residue-Control-Program.pdf","type":"pdf","n\_pages":2,"word\_count":850,"text\_by\_page":["FSIS Guidance for Suggested Reporting Tables of the Government Chemical Residue Control Program NOTE: This document is updated from the 2018 version but does not contain substantive changes to the suggested reporting format. FSIS requests that all eligible countries submit their 2019 Chemical Residue Control Program Plan and 2018 Residue Control Program Results. The tables included in this guidance are to assist Central Competent Authorities (CCAs) provide FSIS with the information requested in FSIS\u2019s Self-Reporting Tool (SRT) question, Government Chemical Residues Testing Programs. FSIS is providing suggested reporting table formats for the annual data submissions of the 2019 Residue Control Program Plan and 2018 Residue Control Program Results that are due to FSIS by May 18, 2019. The use of these reporting table formats is optional; FSIS will review information submitted in other formats. The information that should be submitted includes: \u2022 2019 FSIS Residue Control Plan (Table 1 \u2013 suggested reporting format) 1) Names of individual compounds for each slaughter class or, if

providing a method, then a list of individual compounds for each method 2) Proposed tissue (e.g., muscle, liver, kidney) for sample collection 3) Analytical methodology used to evaluate each compound for regulatory decision making 4) Established tolerance or action level, (e.g., maximum residue limit (MRL) 5) Proposed number of samples for each production class for each chemical compound 6) Criteria used to determine the proposed sampling number (e.g., statistical basis, etc.) 7) Criteria used to determine whether a compound is included or removed from the testing program 8) Processes for reassessing the yearly chemical residue plan and for reviewing the data and identifying specific violations or violation trends 9) Indicate whether livestock (beef, pork, goat, sheep) carcasses are held pending negative laboratory test results before exported to the US \u2022 2018 FSIS Residue Control Program Results (Table 2 \u2013 suggested reporting format) 1) Actual number of samples analyzed for each production class for each chemical compound and number of violative results 2) Description of the CCA\u2019s enforcement strategy in response to violative results Countries testing applicable processed products should include this information in their submission. Regarding the 2019 FSIS Residue Control Annual Plan, FSIS is including the attachment, FSIS Government Residue Control Program, as a reference. This attachment includes sampling and testing frequencies for FSIS government testing programs. The 2019 FSIS Residue Control Annual Plan and the 2018 Residue Control Program Annual Results can be submitted to FSIS by either uploading it into our Public Health Information System (PHIS) under SRT question, Government Chemical Residues Testing Programs, or by submitting it to our International Coordination Executive at: US Department of Agriculture Food Safety and Inspection Service Office of International Coordination Room 3143, South Building 1400 Independence Ave SW Washington D.C. 20250-3700 Fax: 1-202-690-3856 E-mail: InternationalCoordination@fsis.usda.gov", "FSIS Guidance for Suggested Reporting Tables of the Government Chemical Residue Control Program NOTE: This document is updated from the 2018 version but does not contain substantive changes to the suggested reporting format. For your reference, please see the links below for FSIS\u2019s Residue Sampling Plan and Results: \u2022 FSIS Residue Sampling Plans (Blue Book) \u2022 FSIS Residue Sample Results (Red Book) \u2022 FSIS Directive 10,800.11, Residue Sampling, Testing and Other Verification Procedures under the National Residue Program for Meat and Poultry Products

Table 1: Suggested Reporting Table for the 2019 Government Residue Control Program Annual Plan. Please include the following information below for the product categories for which the CCA is currently equivalent or seeking equivalence. (The information provided in the table is for illustrative purposes only)

Species (subspecies)	Compound class	Sampling location (e.g., farm/\ establishment)	Tissue (e.g., kidney, liver, muscle)	Analytical methodology for regulatory decision making	Limit of confirmation (with units)	Action Level or Maximum Residue Level (with units)	Number of samples planned	Bovine (veal, cattle)	Aminoglycosides Neomycin Farm Kidney LC MS\MS
					10 ppb	15 ppb	300		10 ppb

Table 2: Suggested Reporting Table for the 2018 Government Residue Control Program Annual Results. Please include the following information below for the product categories for which the CCA is currently equivalent or if the data exists, seeking equivalence. (The information provided in the table is for illustrative purposes only)

Species (subspecies)	Compound Analyzed	Tissue (e.g., kidney, liver, muscle)	Number of samples analyzed	Number of samples above tolerance or MRL	Violative levels
Bovine (veal, cattle)	Neomycin	Kidney	300	1	50 ppb

Follow-Up Actions Bovine (veal, cattle) Neomycin Kidney 300 1 50 ppb Briefly describe the CCA\u2019s enforcement strategy in response to violative results (e.g., investigation, trace

back, corrective action (root cause), punitive\legal sanctions, etc.) Ex: All suspect carcasses declared unfit for human consumption and destroyed. Full on farm investigations including examination of medicines on farm and animal remedies record were carried out in each case. As appropriate, advice is given to the farmer and follow-up visits take place. 1 FSIS Directive 10,800.1 also available in Arabic, Chinese, Spanish, and Vietnamese translations. 2 Include the compound class for the chemical compound being analyzed. 3 Include the name of the individual chemical compound being analyzed. Please note that compound class alone is not sufficient. 4 Include the regulatory limit for the compound. This may be an \u201caction level\u201d or a \u201cmaximum residue level\u201d.]}, {"file\_name": "FSIS\_GD\_2019\_0016", "title": "Summary of FSIS Government Microbiological Sampling Programs Frequencies", "num": "FSIS-GD-2019-0016", "id": "9dff984e43841f43449dc86b583bc82a3e545c2590746b486de427389b8bcfc1", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/import/Microbiological-Frequencies.pdf", "type": "pdf", "n\_pages": 5, "word\_count": 1408, "text\_by\_page": ["Summary of FSIS Government Microbiological Sampling Programs Frequencies NOTE: This document is updated from the 2018 version. translations.", "Summary of FSIS Government Microbiological Sampling Programs Frequencies NOTE: This document is updated from the 2018 version. It includes revised footnotes. Table 1: Frequency of FSIS Government Microbiological Sampling and Testing for Raw Meat and Poultry Products Product Type or Production Class Pathogen Target(s) Test Portion Frequency (# of samples per establishment)4 Very Small Est (<1,000 lbs./day) Small Est (1,001-50,000 lbs./day) Medium Est (50,001-250,000 lbs./day) Large Est (>250,000 lbs./day) Steer/heifer/cow/bull 5 carcass Salmonella 3-site sponge (300 cm 2 total); with hydrate See footnote 5 See footnote 5 See footnote 5 Raw ground beef/veal E. coli O157:H7 325 grams 1/month 2/month 3/month 4/month Salmonella 325 grams 1/month 2/month 3/month 4/month Raw beef/veal manufacturing trimmings E. coli O157:H7 Entire N60 sample (~325-375grams) 1/month 2/month 3/month 4/month Salmonella Entire N60 sample (~325-375grams) 1/month 2/month 3/month 4/month Non-O157 STEC (O26, O45, O103, O111, O121, and O145) Entire N60 sample (~325-375grams) 1/month 2/month 3/month 4/month Raw beef/veal bench trimmings E. coli O157:H7 Entire N60 sample (~325-375grams) 1/month 2/month 3/month 4/month Raw beef/veal components other than trim (e.g., head meat, cheek meat, weasands, hearts) E. coli O157:H7 325 grams 1/month 2/month 3/month 4/month Salmonella 325 grams 1/month 2/month 3/month 4/month The volume production ranges listed are based on pounds of a specific product type or process category produced per day by a single establishment. Alternatively, the CCA may choose to use the volume of products that are exported to the US to categorize establishments eligible to export in order to determine the appropriate frequency for testing. If the frequency of sampling is based on volume of products exported to the US, the corresponding volume ranges would be: Very Small Est (<20,000 lbs./month exported to the US), Small Est (20,001-100,000 lbs./month exported to the US), Medium Est (100,001-5,000,000 lbs./month exported to the US), Large Est (>5,000,000 lbs./month exported to the US). 5 FSIS suspended official government verification of compliance with the Salmonella performance standards in beef (steers/heifers and cows/bulls) and swine (market hog) carcasses (2011), as well as in raw ground beef (2014), because the percentage of positive findings was very low in carcasses and because of methods changes in ground beef. CCAs need to provide their performance standard criteria for evaluation of Salmonella results, including how the CCA assesses on an ongoing basis whether certified establishments meet performance standards for carcasses (cow/bull, steer/heifer, and swine) and raw ground beef. Alternatively, if the CCA has been following the FSIS standards but wants to make changes to its program, CCAs can request an individual sanitary measure (ISM) determination and submit data to support that their measure provides an equivalent level of public health protection.", "Summary of FSIS Government Microbiological Sampling Programs Frequencies NOTE: This document is updated from the 2018 version. (v2019-001): United States (U.S.) Department of Agriculture Food Safety and Inspection Service  
(FSIS) Responses to the Self-Reporting Tool (SRT)", "num": "FSIS-GD-2019-"}]

0017","id":"cdbd52a9d4c5331e100bb6d97e4a4203085fa5145d7a7daf76e7148f708e415a","corpus":"fsis\_guidelines","source\_page\_url":"https:\V\www.fsis.usda.gov\policy\fsis-guidelines","url":"https:\V\www.fsis.usda.gov\sites\default\files\import\srt-responses.pdf","type":"pdf","n\_pages":45,"word\_count":27759,"text\_by\_page":["FSIS Responses to the SRT (v2019-001) 1 United States (U.S.) Department of Agriculture Food Safety and Inspection Service (FSIS) Responses to the Self-Reporting Tool (SRT) What is the purpose of this document? This document is designed to demonstrate to the Central Competent Authority (CCA) that intends to submit answers to SRT questions the level of detail FSIS needs in those answers for FSIS to determine whether the country\u2019s documented food safety inspection system achieves a level of sanitary protection equivalent to the U.S. system. In this document, FSIS provides answers to the SRT based on our documented national food safety inspection system governing meat, poultry, and egg products. In addition, FSIS has included links to our supporting documentation (i.e., laws, regulations, inspection procedures, sampling plans, and sampling results) within each SRT answer. Furthermore, FSIS altered some answers to SRT questions to provide a more applicable response. For example, SRT question #2, \u201cHow does the CCA ensure that no meat, poultry, or egg products intended for export to the U.S. are adulterated or misbranded (i.e., properly labeled and packaged), and only eligible meat, poultry, and egg products are certified for export to the U.S.? \u201d was answered from the standpoint of ensuring that no meat, poultry, or egg products intended for export from the U.S. are adulterated or misbranded, and only eligible products are certified for export. Information on ensuring that only eligible products are received for importation was provided in a subsequent question (SRT question #3). Who is this document designed for? This document is designed for all countries to use as a reference when providing SRT answers as part of their required annual documentation submission for ongoing equivalence. In addition, this document is a useful tool for countries requesting a reinstatement of equivalence, initial equivalence, or expansion of initial equivalence to demonstrate the type of information that they will need to provide in their SRT submission. How is this document structured? This document was structured to provide the U.S. laws, regulations, and inspection procedures applicable to each SRT answer. The primary issuances noted throughout this document are as follows: \u2022 U.S. laws- Federal Meat Inspection Act, Poultry Products Inspection Act, and Egg Products Inspection Act \u2022 U.S. regulations- Title 9 of the Code of Federal Regulations (9 CFR) chapters 300 to 590 \u2022 FSIS inspection procedures- FSIS Directives In addition, this document provides SRT answers to all commodities (meat, poultry, and egg products) produced under various processing categories. Therefore, not all SRT questions and answers will apply to every country. The following chart identifies which SRT questions the CCA needs to provide answers and supporting documentation for based on the specific products the country is eligible to export or interested in exporting to the U.S. To view which products your country is currently eligible to export to the U.S., refer to FSIS Import Library- Eligible Countries and Products. For more information on HACCP product categorization, please refer to the FSIS Product Categorization Guide. Products SRT Question Numbers Standard SRT questions to be answered for all products 1, 2, 3, 4, 5, 7, 9, 13, 14, 15, 16, 18, 23, 24, 26 Raw-Intact and Raw-Non Intact Beef and Veal 6, 10, 11, 12, 17, 22, 25, 27, 28, 29", "FSIS Responses to the SRT (v2019-001) 2 Raw-Intact and Raw-Non Intact Pork 6, 10, 11, 12, 22, 25, 27, 28 Raw-Intact and Raw-Non Intact Lamb, Mutton, or Goat 6, 10, 11, 12, 17, 22, 25, 27, 28 Raw-Intact and Raw-Non Intact Poultry and Ratites 6,

10, 11, 12, 22, 25, 27, 28 Raw-Intact and Raw-Non Intact Siluriformes Fish 6, 20, 21, 25 Thermally Processed-Commercially Sterile Meat and Poultry Products 6, 25, 33 Not Heat Treated-Shelf Stable Meat and Poultry Products 6, 25, 30, 31, 32 Heat Treated-Shelf Stable Meat and Poultry Products 6, 25, 30, 31, 32 Fully Cooked-Not Shelf Stable Meat and Poultry Products 6, 25, 30 Heat Treated-Not Fully Cooked-Not Shelf Stable Meat and Poultry Products 6, 25, 32 Product with Secondary Inhibitors-Not Shelf Stable Meat and Poultry Products 6, 25, 30, 32 Egg Products 8, 19, 30 Lastly, in this document, the term \u201cestablishments\u201d refers to all official establishments under FSIS inspection eligible to produce meat, poultry, and egg products for domestic commerce and for export (i.e., certified to export product to foreign countries).", "FSIS Responses to the SRT (v2019-001) 3 Component 1 Government Oversight 1. How does the CCA ensure that the laws and regulations governing meat (including beef, veal, pork, sheep, goat, and Siluriformes fish), poultry (including chickens, turkeys, ducks, geese, guineas, ratites, or squabs), and egg products inspection are enforced? The Central Competent Authority (CCA) of the United States (U.S.) is the Food Safety and Inspection Service (FSIS), part of the U.S. Department of Agriculture (USDA), and it is organized and administered as part of the national government. FSIS is the public health regulatory agency responsible for ensuring that domestic and imported meat, poultry, and egg products are safe, wholesome, and correctly labeled and packaged. FSIS inspects domestic and imported meat, poultry, and egg products under the authority of the Federal Meat Inspection Act (FMIA), the Poultry Products Inspection Act (PPIA), and the Egg Products Inspection Act (EPIA). On December 2, 2015, FSIS published the Final Rule \u201cMandatory Inspection of Fish of the Order Siluriformes and Products Derived from Such Fish\u201d (80 FR 75590). This rule amended the Agency\u2019s regulations to establish a mandatory inspection program for fish of the order Siluriformes, both farm-raised and wild-caught, and for products derived from these fish. Further, the rule explains that, because these fish are amenable to the FMIA (21 U.S.C. 601(w)(2)), the Siluriformes inspection program is part of FSIS\u2019s meat inspection program, and is governed by FSIS under the authority of the FMIA. (NOTE: Throughout this SRT, regulatory citations to FSIS\u2019s inspection requirements for Siluriformes fish and fish products are provided. In most cases, these regulations reference the existing regulations for meat and meat food products as applying to Siluriformes products). The authority to enforce these Acts, and maintain a regulatory program aimed at protecting the health and welfare of consumers, is delegated from the Secretary of Agriculture, who is appointed by the President of the United States. In turn, the Secretary of Agriculture appoints a FSIS Administrator to oversee all FSIS activities and program areas, including but not limited to, inspection services, laboratory services and technical support, and training and education. FSIS comprises several program areas (FSIS Organizational Chart), including the Office of Field Operations (OFO), which manages regulatory oversight and inspection of establishments that slaughter, process, import and export meat, poultry and egg products. Inspection services are provided by ten (10) OFO district offices spanning across the U.S. The district offices are responsible for coordinating the activities of local inspection circuits, as well as certifying establishments. FSIS inspection program personnel (IPP) ensure that all provisions in the aforementioned Acts are met and followed by verifying and enforcing that official establishments meet all applicable regulatory requirements in Title 9 of the Code of Federal Regulations (9 CFR) chapters 300 to 590. Among other provisions, these Acts give FSIS the authority and ability to require corrective actions in

establishments and to take additional enforcement measures as necessary when regulatory requirements are not met. FSIS IPP require and verify that establishments implement corrective actions, including measures to prevent recurrence, when the establishment fails to prevent direct contamination or adulteration of product (9 CFR 416.15), or when a deviation from a critical limit occurs (9 CFR 417.3). Furthermore, if an establishment fails to take appropriate corrective actions, FSIS has the authority and ability to take additional enforcement measures. These measures include, but are not limited to, retaining product or rejecting equipment; refusing to allow the marks of inspection to be applied to product; and suspending or withdrawing inspection (9 CFR 500 (meat and poultry), 590.160 (eggs)). (NOTE: The Rules of Practice in 9 CFR 500 apply to fish inspection activities per 9 CFR 561. Throughout this SRT, answers referring to the Rules of Practice in 9 CFR 500 apply to meat and poultry products, including", "FSIS Responses to the SRT (v2019-001) 4 Siluriformes.) Other circumstances under which FSIS would take enforcement measures (e.g., failure to have or maintain a Hazard Analysis and Critical Control Point (HACCP) plan, failure to have or maintain Sanitation Standard Operating Procedures (Sanitation SOPs), or handling or slaughtering livestock inhumanely) are provided in 9 CFR 500 (meat and poultry) and 590.160 (egg products). Instructions to FSIS personnel on the types of enforcement actions that may be taken under 9 CFR 500, and the enforcement methodology to use when taking enforcement actions, are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. For example, when a FSIS OFO district office decides to pursue an enforcement action under 9 CFR 500.3 Withholding or suspension without prior notification, it issues a Notice of Suspension letter. When a FSIS OFO district office decides to pursue an enforcement action under 9 CFR 500.4 Withholding action or suspension with prior notification, it issues a Notice of Intended Enforcement letter. In connection with these enforcement actions, the FSIS OFO district office prepares an Administrative Enforcement Report case file to include establishment documentation, FSIS and establishment communications, supporting documents, evidence collected (as described in FSIS Directive 8010.3 Procedures for Evidence Collection, Safeguarding and Disposal), and verification plans. Additionally, FSIS conducts public health risk evaluations to determine if risk-based, targeted reviews of establishment food safety systems (i.e., food safety assessments) are necessary. These food safety assessments are conducted by FSIS personnel (i.e., Enforcement Investigation and Analysis Officers- EIAOs) who have received advanced training in the assessment and analysis of establishment food safety systems. Some examples of when a FSA may be conducted include, but are not limited to, when an establishment produces adulterated product, or when an establishment produces product associated with an outbreak. FSIS EIAOs follow instructions outlined in FSIS Directive 5100.4 Enforcement, Investigations and Analysis Officer (EIAO) Public Health Risk Evaluation (PHRE) Methodology when conducting a public health risk evaluation to determine whether a food safety assessment is necessary, and FSIS Directive 5100.1 Enforcement, Investigations, and Analysis Officer (EIAO) Comprehensive Food Safety Assessment Methodology when performing food safety assessments. Furthermore, the Acts provide FSIS with the authority to seize and condemn adulterated or misbranded meat, poultry, and egg products in commerce or being transported in commerce (21 U.S.C. 673 (meat), 467(b) (poultry), and 1049 (egg products)). FSIS\u2019s Office of Investigation, Enforcement and Audit (OIEA) is responsible for the enforcement of FSIS criminal, civil, and administrative sanctions and authorities. FSIS OIEA

compliance officers follow instructions outlined in FSIS Directives (8000 series) when performing procedures including, but not limited to, conducting in-commerce surveillance activities (FSIS Directive 8010.1 Methodology for Conducting In-Commerce Surveillance Activities); collecting, safeguarding, and disposing evidence (FSIS Directive 8010.3 Procedures for Evidence Collection, Safeguarding and Disposal); detention and seizure (FSIS Directive 8410.1 Detention and Seizure); determining appropriate action and referring enforcement matters (FSIS Directive 8010.5 Case Referral and Disposition); and writing an investigation report (FSIS Directive 8010.4 Report of Investigation). 2. How does the CCA ensure that no meat, poultry, or egg products intended for export to the U.S. are adulterated or misbranded (i.e., properly labeled and packaged), and only eligible meat, poultry, and egg products are certified for export to the U.S.? FSIS ensures that all meat, poultry, or egg products exported from the U.S. are certified, and not adulterated or misbranded, by enforcing the same laws and regulations for all products produced under FSIS inspection, and by certifying that all products eligible for export adhere to both FSIS requirements and the requirements of the importing country. The FMIA, PPIA, and EPIA provide FSIS with the authority and responsibility to enforce the laws and regulations governing meat, poultry, and egg products inspection, and to certify these products for", "FSIS Responses to the SRT (v2019-001) 5 export. Furthermore, 9 CFR 322.1-322.2 (meat), 381.106 (poultry), 552.1 (Siluriformes) and 590.407 (egg products) list the requirements that must be met prior to FSIS IPP signing an export certificate. These requirements include, but are not limited to, verifying that the product to be exported is \u201cU.S. inspected and passed,\u201d determining that the product is neither adulterated or misbranded, and verifying that the outside container contains an official USDA mark or a mark containing a unique identifier linking the consignment to the export certificate. FSIS IPP verify that any product tested for adulterants by FSIS receives acceptable testing results prior to receiving the mark of inspection and being eligible for distribution in commerce (both domestically and for export). This includes the confirmation of acceptable official government testing results for the following sampled products: raw non-intact beef product or raw intact beef product intended for raw non-intact use that is tested for Shiga toxinproducing Escherichia coli (STEC); RTE products tested for Listeria monocytogenes (Lm), Salmonella, or STEC (RTE beef products); RTE product that passed over food contact surfaces that have been tested for the presence of Lm and Salmonella; and livestock carcasses subject to FSIS testing for veterinary drugs (e.g., antibiotics, sulfonamides, avermectins). When performing export verification activities, FSIS IPP follow instructions provided in FSIS Directive 13,000.5 Public Health Information System Export Certification (for countries active in PHIS) or FSIS Directive 9000.1 Export Certification (for countries not active in PHIS). This export verification activity includes consulting the FSIS Export Library, which lists export requirements by country for meat, poultry, and egg products, to determine the eligibility of shipments for export. This library is updated when a country notifies FSIS of a change in its requirements, and includes information such as certificate requirements, eligible and ineligible products, facility requirements, and labeling requirements. Further, FSIS IPP perform the following activities during export verification: verify that the export application is accurate and complete, and, if necessary, request additional documentation from the applicant (e.g., laboratory testing results, bill of lading, livestock country of origin, Agricultural Marketing Service (AMS) grading certificate, etc.); verify that the correct export mark number is applied; verify that labels meet the requirements of the

receiving country; and, if required, conduct product re-inspection. When not in use, export certificates, official export stamps, and certificate inventory records must be kept under official lock or seal, and any unused export stickers must be returned to FSIS and destroyed. Additional information on IPP export inspection procedures are provided in FSIS Directives 9000.2 Inspection and Export Certification of Livestock Intestines or Casings; 9000.6 Export Certification of Egg Products from Other than Official Egg Products Plants; and 9010.1 Export Products Returned to the United States. The FMIA, PPIA, and EPIA all provide statutory definitions for adulterated or misbranded product (21 U.S.C. 453, 601, and 1033). The circumstances under which FSIS considers product to be adulterated include, but are not limited to, product that bears or contains any poisonous or deleterious substance which may render it injurious to health; product that consists in whole or in part of any filthy, putrid, or decomposed substance or is for any other reason unsound, unhealthful, unwholesome, or otherwise unfit for human food; or product that has been prepared, packed, or held under insanitary conditions whereby it may have become contaminated with filth, or whereby it may have been rendered injurious to health. FSIS considers product to be misbranded if it contains false or misleading labeling. To ensure product is wholesome, unadulterated, and correctly labeled and packaged, FSIS IPP perform routine verification activities in all establishments and enter their inspection results into the Public Health Information System (PHIS), which is a web-based comprehensive data analytic system used to collect, consolidate, and analyze data in order to improve public health. These verification activities include Sanitation SOPs and Sanitation Performance Standards (SPS) verification, HACCP verification, economic adulteration, and labeling verification. The priority and frequency for these verification activities is based on the expected impact on public health. For example, routine verification activities, such as HACCP verification, sanitation verification, and labeling verification are performed by FSIS IPP at least twice per week. For establishments with multiple HACCP process categories (e.g., raw-", "FSIS Responses to the SRT (v2019-001) 6 intact, raw-non intact, fully cooked-shelf stable), routine HACCP verification activities are performed at least twice per week per process category. PHIS distributes the appropriate number of verification activities, including sampling activities, to each inspector\u2019s PHIS verification task list. In addition to the verification activities generated by PHIS at an expected frequency, FSIS IPP can also perform \u201casneeded\u201d verification activities. These are known as \u201cdirected\u201d verification activities and are initiated in response to inspection findings, sample results, or other available information. For example, when FSIS IPP record a noncompliance record in PHIS, PHIS initiates a directed instance of the same verification activity that resulted in the noncompliance. FSIS IPP are also able to initiate directed instances of routine verification activities based on conditions they observe in establishments. Instructions to FSIS IPP on how to schedule and complete verification activities in PHIS are provided in FSIS Directives 13,000.1 Scheduling In-Plant Inspection Tasks in the Public Health Information System (PHIS); 13,000.2 Performing Sampling Tasks in Official Establishments Using the Public Health Information System; and 13,000.5 Public Health Information System Export Certification. If FSIS IPP determine that product may be adulterated or misbranded (as per the definitions provided in the Acts), and the product is not in commerce, FSIS IPP can take a regulatory control action, such as retaining the product, to ensure the product does not enter commerce. This product will remain under FSIS control until the establishment determines product disposition and FSIS

verifies that the product disposition is appropriate. Instructions to FSIS IPP on how and when to take a regulatory control action are provided in FSIS Directive 5000.1 Verifying an Establishment's Food Safety System. Instructions to FSIS personnel, such as FSIS OIEA compliance officers and FSIS OFO District Managers, on the methodology to use when deciding whether to implement administrative enforcement actions are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. Instructions to FSIS OIEA compliance officers on the procedures to follow when taking enforcement actions are provided in FSIS Directive 8010.5 Case Referral and Disposition. In the event that adulterated or misbranded product enters commerce, meat and poultry establishments (including both the receiving and producing establishment) are required to notify the appropriate district office within 24 hours and provide information such as the type, amount, origin, and destination of the adulterated or misbranded product (9 CFR 418.2). In addition, meat and poultry establishments are required to maintain written recall procedures describing their decision making process in determining whether to conduct a product recall, and the method and procedures that will be used to carry out the recall (9 CFR 418.3). Instructions to FSIS IPP on the actions to take when a meat or poultry establishment produces or receives adulterated product are provided in FSIS Directive 8140.1 Notice of Receipt of Adulterated or Misbranded Product. Instructions to FSIS IPP on how to verify that establishments have prepared and are maintaining required written recall procedures, including how and when to document noncompliance, are provided in FSIS Directive 5000.8 Verifying Compliance with Requirements for Written Recall Procedures. Recalls are voluntary and are performed by the establishment responsible for shipping the adulterated or misbranded product into commerce. Although it is an establishment's decision to recall product, FSIS coordinates with the establishment to verify it has properly identified and removed recalled product from commerce by verifying the effectiveness of the establishment's recall activities. FSIS also notifies the public about product recalls. If an establishment refuses to recall adulterated or misbranded product from commerce, or if the recall is inadequate, the Acts provide FSIS with the authority to detain or seize this product (21 U.S.C. 467, 673, and 1049). When there is reason to believe that the products are adulterated, misbranded, or otherwise in violation of the Acts, FSIS personnel follow instructions in FSIS Directive 8410.1 Detention and Seizure when detaining, or preparing a recommendation to seize, meat, poultry, and egg products found in commerce. FSIS's role in voluntary recalls is further described in FSIS Directive 8080.1 Recall of Meat and Poultry Products.

3. How does the CCA ensure that source meat, poultry, or egg products used in processing", "FSIS Responses to the SRT (v2019-001) 7 operations originate from certified establishments in countries that the U.S. has determined have an equivalent meat, poultry, or egg products inspection system (i.e., eligible countries)? The Acts require that imported meat, poultry, and egg products originate from eligible countries and from establishments that are certified to export to the U.S. (21 U.S.C. 466, 620, and 1046). A country becomes eligible following an equivalence determination process completed by FSIS in coordination with the country's CCA. Foreign establishments become eligible when FSIS determines that a country's food safety inspection system achieves a level of sanitary protection equivalent to the level achieved by FSIS, and the foreign country's CCA certifies the foreign establishment as meeting U.S. requirements. The requirements that a foreign inspection system must demonstrate are provided in 9 CFR 327.2 (meat), 381.196 (poultry), 557.2

(Siluriformes), and 590.910 (egg products). Prior to being presented to FSIS for reinspection, importers into the U.S. must file a customs entry form with the appropriate U.S. Customs and Border Protection (CBP) port director and are subject to inspection at the port-of-entry by CBP. CBP verifies that the imported products are permitted entry into the U.S., are represented by the proper paperwork, and comply with USDA Animal and Plant Health Inspection Service (APHIS) regulations, which restrict some products from entering the U.S. due to animal disease conditions in the country of origin. FSIS IPP perform reinspection on all imported product for appearance, condition, certification, and label compliance before the product is allowed entry into the U.S. (9 CFR 327.6 (meat), 381.199 (poultry), 557.6 (Siluriformes), and 590.925 (egg products). In addition, FSIS IPP also perform sampling verification on imported products. FSIS IPP follow instructions outlined in FSIS Directives (9900 series) when performing import reinspection procedures including, but not limited to, performing document review and verifying proper presentation of shipments of imported meat, poultry, and egg products (FSIS Directive 9900.1 Imported Product Shipment Presentation); prioritizing and performing assigned reinspections (FSIS Directive 9900.2 Import Reinspection of Meat, Poultry, and Egg Products); label verification (FSIS Directive 9900.5 Label Verification of Imported Meat, Poultry, and Egg Products); and sampling and testing imported products for adulterants recognized by FSIS (including withholding the mark of inspection pending acceptable test results) (FSIS Directive 9900.6 Laboratory Sampling Program for Imported Meat, Poultry, and Egg Products and FSIS Directive 14,100.1 Speciation, Residue, and Salmonella Testing of Fish of the Order Siluriformes at Official Import Inspection Establishments). Instructions to FSIS IPP on how to perform import reinspection on Siluriformes fish and fish products are provided in FSIS Directive 14,950.1 Inspection Program Personnel Responsibilities at Official Import Inspection Establishments That Receive Shipments of Siluriformes Fish and Fish Products. Once inspected and passed, imported product is stamped with a USDA inspection legend and enters domestic commerce. All meat, poultry, and egg products entering official establishments are required to be inspected and passed and contain a USDA inspection legend per 9 CFR 318.1 (meat), 381.145 (poultry) and 590.424 (egg products). FSIS IPP verify that meat, poultry, and egg products source material meet this regulatory requirement when performing routine government verification activities.

4. How does the CCA ensure that the same set of laws, regulations, and policies are applied consistently to all establishments certified to export meat, poultry, or egg products to the U.S.? FSIS ensures that the same set of laws, regulations, and policies are applied consistently to all establishments through a uniform system of conducting government verification activities to ensure that these establishments adhere to all statutory provisions and regulatory requirements. In addition, 9 CFR 302 (meat), 9 CFR 381 subpart D (poultry), 9 CFR 532 (Siluriformes) and 9 CFR 590 (egg products) require that all establishments, producing product for sale or transportation in domestic commerce, apply for and receive inspection services unless operating under one of the exemptions defined in the "FSIS Responses to the SRT (v2019-001) 8 regulations. (NOTE: FSIS does not allow product produced under an exemption to be exported.) FSIS district office personnel are responsible for overseeing and managing the establishment certification process. Prior to granting FSIS inspection services at an establishment, FSIS district office personnel review the establishment's submitted application for completeness. In addition, 9 CFR 304.3 (meat), 9 CFR 381.22 (poultry), and 9 CFR 532.2 (Siluriformes) list the requirements an establishment must demonstrate prior to being

granted Federal inspection and include written Sanitation SOP\u2019s, written recall procedures, a hazard analysis, and a validated HACCP plan. The requirements that an egg products establishment must demonstrate prior to receiving inspection are listed in 9 CFR 590.146, and include an initial survey by FSIS IPP to verify adequate facilities and the submission of drawings\specifications. (NOTE: Egg products establishments are also required to submit updated drawings\specifications when making significant modifications to the interior of their facilities.) FSIS supervisory personnel conduct on-site visits to verify these requirements are met prior to granting an establishment Federal inspection. Instructions to FSIS supervisory personnel on how to verify the appropriate regulatory requirements are met prior to granting Federal inspection are provided in FSIS Directive 5220.1 Granting or Refusing Inspection; Voluntary Suspending or Withdrawing Inspection; and Reinstating Inspection under PHIS (meat and poultry) and FSIS Directive 5030.5 Review of Egg Products Plants Drawings and Specifications (egg products). Once an establishment is granted Federal inspection, it is considered an official establishment and is certified to produce meat, poultry, or egg products for domestic commerce and export. FSIS maintains a list of all official establishments in its Meat, Poultry, and Egg Product Inspection Directory (MPI). Furthermore, FSIS has the authority and ability to withdraw a meat or poultry establishment\u2019s grant of inspection under certain circumstances, such as failure to maintain a HACCP plan or Sanitation SOP\u2019s (9 CFR 500.6). Likewise, FSIS has the authority and ability to withdraw an egg products establishment\u2019s grant of inspection under certain circumstances, such as failure to maintain premises, facilities, and equipment in a satisfactory state of repair (9 CFR 590.160). Instructions to FSIS personnel on the methodology to use when determining whether to refuse, deny, suspend, or withdraw inspection services are provided in FSIS Directive 8010.5 Case Referral and Disposition. FSIS disseminates information regarding FSIS requirements from FSIS headquarters to FSIS IPP through written issuances, webinars, classroom training, and supervisory visits. In addition to the rules and regulations published in the Federal Register and Code of Federal Regulations (9 CFR), FSIS disseminates information to FSIS IPP on current FSIS requirements and policies through the issuance of FSIS Directives and FSIS Notices. FSIS Directives provide official communications and instructions to FSIS IPP in carrying out their functions. FSIS Notices are time sensitive materials issued to provide instruction in support of workplace policies, procedures and food safety regulations and expire one year from the date of publication. If the information provided in the FSIS Notice is still applicable after one year, the FSIS Notice is reissued or the information is incorporated into a FSIS Directive. Furthermore, FSIS IPP often perform verification activities in response to the issuance of a FSIS Directive or FSIS Notice to verify the regulatory requirements (described in the issuance) are met. These are typically \u201cdirected\u201d PHIS verification activities, which are in addition to the routine verification activities generated by PHIS. In addition, FSIS provides administrative and technical support on meeting FSIS requirements to FSIS IPP and establishments through various resources, including askFSIS, and various education and training materials. AskFSIS is a web-based application that allows customers to submit policy-related and technical questions to specific policy staffs (e.g., labeling, sampling, import\export). Furthermore, FSIS publishes compliance guidelines to aid industry in understanding and complying with FSIS policies. The compliance guidelines are intended to be guidance documents and are not regulatory requirements. These guidelines can be found under the Compliance Guides Index on the FSIS

website.", "FSIS Responses to the SRT (v2019-001) 9 For information on exports, FSIS provides an export certification checklist on the FSIS website, which offers an overview of the steps necessary when an establishment wants to export meat, poultry, or processed egg products from the U.S. FSIS also offers an electronic mail subscription service, which allows interested parties to sign up to receive notifications on any information or policy changes regarding exports. 5. How does the CCA ensure that government inspection personnel assigned to certified establishments exporting meat, poultry, or egg products to the U.S. are employees of and paid by the government? FSIS IPP are employed directly by the U.S. government on a permanent or intermittent basis, and are eligible to perform all applicable inspection duties, including: the ante-mortem inspection of livestock and poultry; the post-mortem inspection of each and every livestock carcass, head, and viscera and poultry carcass and viscera<sup>1</sup>; sanitation and HACCP verification activities in all meat and poultry establishments; the continuous inspection of egg products; and the official government verification sample collection activities in meat, poultry, and egg products establishments. The FMIA (21 U.S.C.) affords the Secretary of Agriculture the authority to \u201cappoint\u201d inspectors to examine and inspect all meat food products prepared for commerce in any slaughtering, meat-canning, salting, packing, rendering, or similar establishment (\u00a7 606). This includes inspectors examining and inspecting all amenable species (e.g., cattle, sheep, swine, and goats) before slaughter (\u00a7 603), performing post-mortem examination on each and every carcass and its parts (\u00a7 604), and assessing sanitary conditions (\u00a7 608). The PPIA (21 U.S.C. 453(k)) defines an inspector as an employee or official of the U.S. Government authorized by the Secretary of Agriculture to inspect poultry and poultry products. Authorized inspectors shall perform ante-mortem inspection (\u00a7455(a)), post-mortem inspection of each carcass (\u00a7455(b)), and inspect the sanitary practices of the premises, facilities, and equipment (\u00a7456(a)). The EPIA (21 U.S.C. 1033(k)) defines an inspector as any employee or official of the U.S. Government authorized to inspect eggs or egg products. FSIS\u2019s regulatory definition for an inspector is found in 9 CFR 300.4. Further, all FSIS employees are paid directly by the national government through payments deposited directly into their bank accounts (Public Law 104-134). Lastly, to avoid conflict of interest, FSIS maintains prescriptive requirements in 9 CFR 306.4. These requirements include prohibiting FSIS IPP (including supervisory personnel) from working at an establishment where a member of his or her family is employed by the operator of the establishment; and prohibiting FSIS IPP from acquiring product from any establishment unless the product is purchased from a store or outlet open to the general public, and at a price paid by the general public. 6. How does the CCA ensure that government inspection occurs continuously during slaughter operations, and at least once per production shift during the processing of meat or poultry intended for export to the U.S.? The Acts require that FSIS provide government inspection in all meat and poultry slaughter and processing (i.e., non-slaughter) establishments, and egg products establishments. Both the FMIA and 1 Under FSIS\u2019s New Poultry Inspection System (NPIS), the government inspector\u2019s visual inspection of each carcass also serves as the inspection of the viscera if the inspector\u2019s condemnation of a carcass also requires condemnation of the corresponding viscera.", "FSIS Responses to the SRT (v2019-001) 10 PPIA require that government inspection personnel conduct ante-mortem and post-mortem inspection in meat and poultry slaughter establishments (21 U.S.C. 455, 603, and 604). The regulatory requirements for government

inspection during ante-mortem inspection are provided in 9 CFR 309 (meat) and 9 CFR 381.70 (poultry). The regulatory requirements for government inspection during post-mortem inspection are provided in 9 CFR 310 (meat) and 381.76 (poultry). Furthermore, the regulations require that post-mortem inspection be conducted on each and every carcass, or bird, and its parts. In addition, FSIS requires that FSIS IPP in all meat and poultry processing establishments conduct inspection activities at least once per shift (21 U.S.C. 455 and 606). These provisions are codified in 9 CFR 307.4, which requires that any operation requiring inspection be conducted under the supervision of a FSIS employee, meaning a government inspector conducts verification activities at least once per shift, during meat and poultry processing operations. FSIS identifies a \u201cshift\u201d as eight (8) consecutive hours (9 CFR 307.4). To ensure that all establishments receive and maintain adequate inspection coverage, establishments are required to submit work schedules to FSIS for review and approval prior to being granted Federal inspection. If an establishment wishes to operate outside of its approved work schedule, including during overtime periods, the proposed change must be submitted for FSIS approval (9 CFR 307.4). Furthermore, FSIS IPP must receive supervisory approval prior to scheduled absences to ensure adequate inspection coverage. In the case of an unscheduled absence, FSIS supervisory personnel will assign IPP to provide inspection coverage at the establishment.

7. How does the CCA ensure that government inspection personnel have appropriate educational credentials, disciplinary backgrounds, and training to carry out their inspection tasks? FSIS hires FSIS IPP through the Federal Government\u2019s official employment site, USAJOBS. Each job posting on this site contains basic qualifications, such as specific experience or education requirements, that must be demonstrated in the applicant\u2019s submission for an FSIS IPP position. Further, all FSIS veterinarians are required to possess a Doctor of Veterinary Medicine professional degree. All FSIS employees are also subject to a background investigation and screening assessment prior to being hired. Additional information on the requirements for FSIS IPP positions can be found under Careers on the FSIS website. In addition, FSIS conducts classroom training and on-the-job training to ensure that inspection personnel have the appropriate training to carry out their inspection tasks. All FSIS IPP responsible for conducting government verification activities in establishments attend a month long training session on essential FSIS verification activities prior to beginning their assignments. Topics discussed during this initial training session include, but are not limited to, HACCP verification, Sanitation SOP and SPS verification, and labeling verification. At the completion of the month long training session, FSIS IPP must demonstrate a competent knowledge of all course material by passing a written examination. Other training sessions include Slaughter Inspection, Public Health Veterinarian (PHV) training, and Egg Products training. In addition to classroom training, FSIS IPP also take courses on various topics, such as export verification, through an online system called AgLearn. Additional information on the various training opportunities available to FSIS IPP can be found under Workforce Training on the FSIS website.

8. How does the CCA ensure continuous government inspection during the processing of egg products designated for export to the U.S.? Continuous government inspection during the processing of egg products is mandated in the EPIA (21 U.S.C. 1034) and implemented through the regulatory requirement in 9 CFR 590.24. In addition, "FSIS Responses to the SRT (v2019-001) 11 \u201cprocessing\u201d is defined in 9 CFR 590.5 as the \u201cmanufacturing of egg products, including breaking eggs or filtering, mixing, blending,

pasteurizing, stabilizing, cooling, freezing or drying, or packaging egg products at official plants.\u201d The labeling of egg products and final product examinations are also considered processing activities. FSIS IPP are on the premises during operations, and conduct inspection activities (both observations and records review) that include, but are not limited to, sanitation verification, food safety and operational verification, review of monitoring records, and verification of time\temperature at critical points in the operation. Furthermore, FSIS has determined that continuous inspection is not required during the entirety of the stabilization processing step and the heat treatment of dried egg whites. In these situations, the inspector is required to be present at the beginning and end of these processing steps.

9. How does the CCA ensure adequate oversight of laboratories that perform analyses for official government sampling and testing programs for meat, poultry, or egg products that are exported to the U.S., including oversight to ensure that laboratories conducting official government analyses comply with the general quality assurance and control criteria provided in International Organization for Standardization (ISO)\International Electrotechnical Commission (IEC) Guide 17025? FSIS ensures that every establishment producing products for domestic commerce or for export is included in official government chemical residue and microbiological sampling and testing programs by assigning official government verification sampling activities to FSIS IPP through PHIS. FSIS ensures that every product for which there is a pathogen performance standard is considered for official government microbiological verification testing. In addition, official government verification testing for chemical residues is assigned to FSIS IPP in establishments producing product eligible for residue testing. The frequency of official government verification sampling and testing is typically determined by the amount of eligible product type (e.g., beef manufacturing trimmings tested for STEC) being produced (production volume). FSIS collects product volume information through PHIS. In all establishments, FSIS IPP routinely verify that establishment profiles in PHIS are up-to-date and accurately reflect which product groups the establishment is producing, and the average daily volumes of the product groups being produced. Instructions to FSIS IPP on how to maintain accurate establishment profiles in PHIS, including instructions on how to enter accurate production volume information, are provided in FSIS Directive 5300.1 Managing the Establishment Profile in the Public Health Information System (meat and poultry) and FSIS Directive 5030.2 Managing the Establishment Profile in the Public Health Information System (PHIS) for Egg Products Inspection. For imported products, the type of inspection verification PHIS assigns to the imported product informs IPP when samples are to be collected and sent for laboratory analysis. Additional information on the laboratory types of inspections assigned to FSIS IPP in import establishments can be found in FSIS Directive 9900.6 Laboratory Sampling Program for Imported Meat, Poultry, and Egg Products. FSIS oversees three (3) national FSIS Field Service Laboratories, which are responsible for coordinating and conducting laboratory analytical services for official microbiological and chemical samples. FSIS\u2019s Office of Public Health Science (OPHS) maintains direct oversight over all three national laboratories, and provides scientific technical support to other FSIS program areas. In addition, FSIS administers the Accredited Laboratory Program (ALP), which accredits nonfederal analytical chemistry laboratories to analyze official government samples of meat and poultry food products for moisture, protein, fat, and salt content and\or certain classes of chemical residues. Currently, the specific chemical residues included in analyses conducted by ALP laboratories are chlorinated hydrocarbons, polychlorinated

biphenyls, sulfonamides, nitrosamines, and arsenic.", "FSIS Responses to the SRT (v2019-001) 12 All FSIS Field Service laboratories that conduct analyses for official government samples of meat, poultry, or egg products are ISO 17025 accredited, and have established and implemented quality control procedures. The ISO 17025 accreditation certificates for FSIS\u2019s three Field Service laboratories are available via the following links: FSIS Western Laboratory, FSIS Eastern Laboratory, and FSIS Midwestern Laboratory. Within OPHS, the Laboratory Quality Assurance Staff (LQAS) is responsible for laboratory quality management system oversight, and maintaining and distributing system policy and procedures. LQAS managers within each of the three laboratories verify that quality control procedures for laboratories are established, effective, and followed by conducting internal audits of each Field Service Laboratory at least three times per year to verify compliance with ISO 17025 requirements, accreditation body requirements (i.e., American Association for Laboratory Accreditation (A2LA) Food Testing Program Requirements), and quality management system requirements. Regarding external laboratory audits, the A2LA evaluates and assesses each FSIS Field Service laboratory for on-going compliance with ISO\IEC 17025:2005 requirements by performing annual audits of the laboratory system. In addition to the annual A2LA audit, OPHS LQAS auditors also conduct external audits. FSIS\u2019s national laboratories maintain quality control procedures that are consistent with the requirements in ISO 17025 including: monitoring the validity of tests and calibrations, implementing and documenting quality control procedures for each batch of samples; verifying that testing, calibration, and sampling methods are fit for purpose; requiring non-standard methods to be validated; ensuring that samples tested meet the acceptance criteria for releasing batches; and taking corrective actions for all samples outside the acceptance criteria. In addition, FSIS laboratories participate in proficiency testing for all accredited test methods. FSIS laboratories also perform duplicate analysis, and calibration of instruments and media. Furthermore, quality control samples are tracked to ensure the validity of the results. To ensure sample integrity, reliability, and chain of custody is maintained in all official samples collected and tested under FSIS\u2019s sampling programs, samples remain under direct FSIS control while in the establishment and in the FSIS laboratories, and under FSIS seal during transport from the establishment to the laboratory. Instructions to FSIS IPP on how to use sample seals and identity labels to ensure sample integrity and identity are provided in FSIS Directive 7355.1 Use of Sample Seals for Laboratory Samples and Other Applications. In addition, sample status and sample analysis result information are reported electronically to FSIS personnel and establishments through the Laboratory Information System-Direct (LIMS-Direct), which updates data every 15 minutes. Instructions to FSIS IPP on how to access the LIMS-Direct system are provided in FSIS Directive 10,210.5 FSIS Sampling Data Reporting Through Laboratory Information Management System - Direct. Furthermore, FSIS provides quarterly letters to establishments to summarize official government sampling results covering a 12-month window. Lastly, in the event of a positive or violative result for an official government sample, FSIS does not re-test the sample. Component 2 Government Verification of Food Safety and Other Consumer Protection Requirements 10. How does the CCA ensure that animals are handled and slaughtered humanely? The FMIA (21 U.S.C. 603b, 610) and the Humane Methods of Livestock Slaughter Act (7 U.S.C. 1901, 1902, and 1906) both mandate that the handling and slaughter of livestock be carried out by humane methods. Further, 7 U.S.C. 1902 provides the two acceptable livestock slaughter methods that

FSIS", "FSIS Responses to the SRT (v2019-001) 13 considers to be humane. These methods include rendering the livestock insensible to pain by a single blow or gunshot, or electrical, chemical, or other means that is rapid and effective, prior to shackling, hoisting, and cutting the animal; or the simultaneous and instantaneous severance of the carotid arteries causing a loss of consciousness. For livestock, the statutory provisions are implemented through FSIS IPP enforcing and verifying compliance with 9 CFR 313. These prescriptive requirements include, but are not limited to, maintaining pens, driveways, and ramps in good repair and free from sharp or protruding objects; slip resistant or waffled flooring; providing water in all holding pens and, if held longer than 24 hours, access to feed; and the prohibition against dragging disabled animals while conscious. 9 CFR 313 also prescribes the requirements for using carbon dioxide, captive bolt, gunshot, and electric current during livestock slaughter. FSIS IPP perform verification of the establishment's humane handling activities for livestock during each shift that animals are slaughtered, or when animals are on site, and record the results in PHIS. Furthermore, 9 CFR 313.50 lists the regulatory control actions that IPP can take if they observe an incident of inhumane slaughter or handling. Examples of noncompliance with humane handling requirements include, vehicles or ramps not properly positioned leading to the injury of animals, animals slipping and falling because of poor footing or lack of slip resistant flooring, holding pens lacking access to water, or animals regaining consciousness after stunning.

Instructions to FSIS IPP, including how and when to document noncompliance and take enforcement actions, are provided in FSIS Directive 6900.2 Humane Handling and Slaughter of Livestock. Instructions to District Veterinary Medical Specialists conducting humane handling verification visits are provided in FSIS Directive 6910.1 District Veterinary Medical Specialist (DVMS) Work Methods. Furthermore, establishments in violation of the statutory provisions and regulatory requirements, requiring the handling and slaughter of livestock to be carried out through humane methods, are subject to the enforcement actions in 9 CFR 500, such as suspension and withdrawal of inspection. Regarding poultry establishments, 9 CFR 381.65(b) requires that poultry be slaughtered in accordance with good commercial practices in a manner that will result in thorough bleeding of the carcasses and ensure that breathing has stopped prior to scalding. Also, any poultry carcass showing evidence of having died from causes other than slaughter is considered adulterated and must be condemned (21 U.S.C. 453(g)(5), 9 CFR 381.90). FSIS IPP perform verification activities during each shift that poultry is slaughtered to verify compliance with good commercial practices. Examples of noncompliance with the requirement for good commercial practices include, establishment employees mistreating birds or handling them in a way that will cause death or injury, prevent thorough bleeding, or result in excessive bruising; stunning or bleeding equipment that is not functioning properly; or an increased number of bruised wings or legs. Instructions to FSIS IPP on how to verify good commercial practices in poultry establishments, including how and when to document noncompliance, are provided in FSIS Directive 6110.1 Verification of Poultry Good Commercial Practices. 11. How does the CCA ensure that government inspection personnel perform ante-mortem inspection of livestock and poultry prior to slaughter? The FMIA and PPIA both mandate that government inspectors perform ante-mortem inspection of all livestock (21 U.S.C. 603) and poultry (21 U.S.C. 455(a)) in establishments. These statutory provisions are codified in 9 CFR 309.1(livestock) and 9 CFR 381.70 (poultry). 9 CFR 309.1 requires that all livestock receive ante-mortem inspection on the

day of slaughter, prior to entering an establishment. Therefore, if an establishment does not present animals for ante-mortem inspection in accordance with 21 U.S.C. 603 and 9 CFR 309.1, FSIS IPP are not able to determine that carcasses are not adulterated and, therefore, cannot permit the carcasses to be marked as \u201cinspected and passed.\u201d Carcasses from animals that did not receive ante-mortem inspection are condemned in", "FSIS Responses to the SRT (v2019-001) 14 accordance with procedures in 9 CFR 314. Furthermore, FSIS does not allow for the emergency slaughter of cattle that did not receive ante-mortem inspection (9 CFR 309.12). 9 CFR 309.2-309.18 provide the requirements for the proper disposition of certain conditions. For example, 9 CFR 309.2 provides the conditions under which livestock would be determined to be \u201cU.S. Suspect\u201d (e.g., livestock that reacted to a tuberculin test). \u201cU.S. Suspect\u201d livestock are set apart and slaughtered separately from other livestock, and identified with a \u201cU.S. Suspect\u201d metal ear tag that can only be removed by FSIS personnel. In addition, any livestock found to be dead, dying, or diseased (per the conditions listed in 9 CFR 311) are identified with a metal ear tag as \u201cU.S.

Condemned\u201d and disposed of per the requirements in 9 CFR 309.13 and 314. Other conditions requiring a disposition of \u201cU.S. Condemned\u201d include, but are not limited to, all non-ambulatory disabled cattle, including nonambulatory veal calves; and livestock showing symptoms of certain metabolic, toxic, nervous or circulatory disturbances, nutritional imbalances, or infectious or parasitic diseases. After determining that livestock is \u201cU.S. Condemned,\u201d FSIS Public Health Veterinarians (PHVs) verify that the establishment disposes the condemned livestock in accordance with 9 CFR 314 and maintains the required records (9 CFR 320). During ante-mortem livestock inspection, FSIS IPP observe the animals at rest and in motion (from both sides) to assess the overall condition of each animal; the degree of alertness, mobility, and breathing; and whether there are any unusual swellings or any other abnormalities. In addition, FSIS IPP routinely verify that only livestock that have passed ante-mortem inspection are moved to slaughter, and that the number of livestock receiving ante-mortem inspection is equal to the number of livestock slaughtered. FSIS IPP then enter ante-mortem disposition data into PHIS. Instructions to FSIS IPP on conducting ante-mortem livestock inspection are provided in FSIS Directive 6100.1 Antemortem Livestock Inspection. Regarding poultry establishments, 9 CFR 381.70(a) requires that poultry receive ante-mortem inspection on the day of slaughter. 9 CFR 381.71-381.75 lists the conditions under which a bird would be condemned, segregated, or quarantined and identified as either \u201cU.S. Suspect\u201d or \u201cU.S. Condemned.\u201d \u201cU.S. Suspect\u201d birds are set apart and slaughtered separately from other birds, and all birds found to be \u201cU.S.

\u201cU.S. Suspect\u201d or \u201cU.S. Condemned\u201d are identified with a tag that can only be removed by FSIS personnel. Further, the list of diseases or conditions that would render a bird \u201cU.S. Condemned\u201d are provided in 9 CFR 381.80-381.93 and include, but are not limited to, avian leucosis, septicemia or toxemia, and cadavers. Condemned birds are disposed of in accordance with procedures in 9 CFR 381.95. During ante-mortem poultry inspection, FSIS IPP observe the overall condition of the birds, and determine whether there are any unusual swellings or any other abnormalities on the birds, such as edema of the wattles, gasping and sneezing, off-colored feces, diarrhea, skin lesions, lameness, torticollis (e.g., wry neck), or bone or joint enlargement. After completing ante-mortem inspection, FSIS IPP enter ante-mortem disposition data into PHIS. Instructions to FSIS IPP on how to perform ante-mortem poultry

inspection are provided in FSIS Directive 6100.3 Ante-mortem and Post- mortem Poultry Inspection. Instructions to FSIS IPP on how to perform ante-mortem inspection of ratites (e.g., ostrich, emu) are provided in FSIS Directive 6170.1. 12. How does the CCA ensure that government inspection personnel perform post-mortem inspection of each and every livestock carcass, head, and viscera and each and every poultry carcass and viscera during and after the slaughter of livestock and poultry? NOTE: In this SRT answer, the term \u201conline\u201d FSIS IPP refers to government inspectors working on the production line and performing post-mortem inspection procedures on each and every livestock carcass," "FSIS Responses to the SRT (v2019-001) 15 head, and viscera and each and every poultry carcass and viscera2. The term \u201coffline\u201d FSIS IPP refers to government inspectors performing verification activities throughout the establishment (e.g., HACCP, sanitation, zero tolerance). Offline FSIS IPP do not remain on the production line performing inspection activities throughout the day. Offline FSIS IPP are also referenced in SRT question #22. Post-mortem inspection of each and every livestock carcass, head, and viscera and poultry carcass and viscera3 by government inspectors during and after slaughter is provided for in the FMIA (21 U.S.C. 604) and PPIA (21 U.S.C. 455(b)). These statutory provisions are codified in 9 CFR 310.1(livestock) and 9 CFR 381.76 (poultry). Livestock establishments are required to use an identifying device (e.g., ear tag, back tag) identifying all carcass parts (e.g., head, tongue, viscera) to the rest of the carcass (9 CFR 310.2) until post-mortem inspection by FSIS IPP is complete. Further, any carcass or part identified as either unfit for food purposes or adulterated, and requiring subsequent inspection, is marked with a \u201cU.S. Retained\u201d tag and retained by FSIS IPP pending final inspection by a FSIS PHV. If, at final inspection, the FSIS PHV then determines that the carcass or part is unsound, unhealthful, unwholesome, or otherwise adulterated, the carcass or part is marked as \u201cU.S. Inspected and Condemned\u201d and disposed of in accordance with the requirements in 9 CFR 314. 9 CFR 310.1 prescribes livestock government inspection staffing standards detailing how many inspectors must be present at each station dependent on maximum slaughter line speed. 9 CFR 310 also contains the requirements for presentation (9 CFR 310.12); the procedures for the disposition of thyroid glands, laryngeal muscle tissue, and lungs; and the procedures for the inspection of kidneys and mammary glands. The requirements for identifying and handling carcasses or components with certain disease conditions (e.g., tuberculosis, actinomycosis, melanosis) are provided in 9 CFR 311. In addition, FSIS recognizes fecal material, ingesta, and milk on livestock carcasses or carcass parts as common vehicles for microbial pathogens that cause foodborne illness and requires adequate removal of the contamination prior to passing inspection (9 CFR 310.17-310.18). Online FSIS IPP perform post-mortem inspection procedures on each and every livestock carcass, head, and viscera to verify that the carcasses and parts are wholesome and not adulterated, including inspection procedures to ensure that each and every livestock carcass, head, and viscera are free of visible fecal material, ingesta, and milk. FSIS Directive 6100.2 Post-mortem Livestock Inspection provides instructions to online FSIS IPP on how to perform livestock post-mortem inspection on each and every carcass and carcass part (e.g., procedures for examining the head, carcass, and viscera of cattle, calves, swine, sheep, and lamb), and instructions to offline FSIS IPP on how and when to document noncompliance. For example, when examining cattle heads presented with the tongue inside the head, online FSIS IPP are instructed to observe the head's surfaces and eyes, and incise and observe the mandibular, parotid, medial, and lateral

retropharyngeal lymph nodes. Further, FSIS Directive 6100.2 Post-mortem Livestock Inspection provides instructions to online FSIS IPP on the procedures to take if they observe fecal, ingesta, or milk contamination on a livestock carcass, head, or viscera during post-mortem inspection procedures. For example, when online FSIS IPP observe fecal, ingesta, or milk contamination at the final carcass inspection, they are to stop the slaughter line (unless the establishment has a rail-out loop) to allow establishment personnel to trim the contaminated carcass. Online FSIS IPP then re-inspect the trimmed carcass to verify that the contamination was removed in a sanitary manner (9 CFR 310.18(a)). If online FSIS IPP at the final carcass station believe that the establishment's rail-out procedure is inadequate to prevent carcass accumulation or cross-contamination of other carcasses; or the establishment's slaughter or dressing processes are not under control based on repeated presentation of contaminated carcasses for post-mortem inspection, the online FSIS IPP notify 2 Under FSIS' New Poultry Inspection System (NPIS), the government inspector's visual inspection of each carcass also serves as the inspection of the viscera if the inspector's condemnation of a carcass also requires condemnation of the corresponding viscera. 3 See Footnote 2,"FSIS Responses to the SRT (v2019-001) 16 the FSIS inspector-in-charge (IIC). The IIC will perform additional verification activities, such as a livestock zero tolerance verification activity, to verify the adequacy of the establishment's procedures. Instructions to offline FSIS IPP on how to perform livestock verification activities are provided in FSIS Directive 6420.2 Verification of Procedures for Controlling Fecal Material, Ingesta and Milk in Slaughter Operations. Instructions to FSIS PHVs on how to make post-mortem livestock dispositions for select diseases and conditions are provided in FSIS Directive 6100.6 Post-mortem Dispositions for Public Health Veterinarians. After completing post-mortem livestock inspection, FSIS IPP record their inspection findings, along with daily slaughter data, in PHIS. Regarding poultry establishments, 9 CFR 381.76(a) requires post-mortem inspection for each and every poultry carcass and viscera4. The specific post-mortem inspection procedures depend on the type of post-mortem inspection system used by the establishment. 9 CFR 381.76 lists the six (6) types of postmortem inspection systems and the requirements for each system (i.e., Traditional Inspection, Streamlined Inspection System (SIS), New Line Speed (NELS) Inspection System, New Poultry Inspection System (NPIS), New Turkey Inspection System (NTI), and Ratite Inspection). Maximum line speeds for each inspection system are provided in 9 CFR 381.67 (traditional), 381.68 (NTI), 381.69 (NPIS), and 381.76 (NELS and SIS). Under all poultry post-mortem inspection systems, FSIS IPP conduct post-mortem inspection for each and every poultry carcass and look for condemnable conditions (e.g., septicemia, toxemia), as specified in 9 CFR 381.80-381.94. Under every poultry postmortem inspection system except NPIS, FSIS IPP conduct post-mortem inspection for each and every poultry viscera and look for condemnable conditions (e.g., tumor, inflammatory process). Adulterated product that cannot be reprocessed or reconditioned (i.e., by means of online antimicrobial intervention; offline vacuuming, washing, or trimming) is condemned under the supervision of a government inspector and disposed of in accordance with the requirements in 9 CFR 381.95. Examples of condemnable conditions in poultry carcasses include, but are not limited to, tuberculosis (9 CFR 381.81), septicemia or toxemia (9 CFR 381.83), and cadavers (9 CFR 381.90). In establishments operating under NPIS, offline FSIS government inspectors perform hourly verification checks to verify that carcasses are free of visible fecal material and septicemia or toxemia before the carcasses are presented to the

online FSIS government inspector for inspection. In addition, online FSIS government inspectors performing verification activities at establishments operating under NPIS continually verify that the establishment has properly trimmed, sorted (i.e., identified and disposed of poultry carcasses or parts exhibiting condemnable conditions), and reprocessed all carcasses; and carcasses are free from visible fecal material (as required per 381.65(f)) and septicemia or toxemia, before the carcasses enter the chiller. Furthermore, FSIS requires NPIS establishments slaughtering young chicken to notify FSIS IPP prior to the slaughter of each new flock to allow the government inspection of viscera for avian visceral leukosis (9 CFR 381.76(b)(6)(iv)). Instructions to online FSIS IPP on how to perform post-mortem poultry inspection, including dispositions for certain diseases, are provided in FSIS Directive 6100.3 Ante-mortem and Post-mortem Poultry Inspection. For example, when performing online post-mortem inspection, FSIS IPP are instructed to observe the inner surfaces of the carcass for yellow scabbed areas between the skin and subcutaneous tissue of the flaps that could indicate inflammatory process. Instructions to FSIS IPP on how to perform online and offline post-mortem inspection procedures at poultry slaughter establishments operating under NPIS are provided in FSIS Directive 6500.1 New Poultry Inspection System: Post-Mortem Inspection and Verification of Ready-To-Cook Requirement. Instructions to FSIS IPP on how to perform post-mortem inspection of ratites are provided in FSIS Directive 6170.1. After completing post-mortem poultry inspection, FSIS IPP record their inspection findings, along with daily slaughter data, in PHIS.

4 See Footnote 2", "FSIS Responses to the SRT (v2019-001) 17 13. How does the CCA ensure that a representative of the government inspection system makes periodic supervisory visits to each certified establishment to evaluate the performance of inspection personnel? FSIS ensures that FSIS supervisory personnel make periodic supervisory visits to each establishment for the purpose of evaluating the performance of FSIS IPP by requiring that FSIS supervisors conduct at least two (2) in-plant performance reviews for each and every inspector per year. These reviews consist of firsthand, onsite observations to assess FSIS IPP's demonstrated knowledge of job requirements, appropriate regulatory decision making, and ability to execute inspection and verification procedures. Specifically, FSIS supervisory personnel assess FSIS IPP performance in the following areas: antemortem inspection; post-mortem inspection; humane handling and good commercial practices; Sanitation SOPs and Sanitation Performance Standards (SPS) verification; HACCP verification; food defense; economic adulteration and labeling verification; sampling methodology and collection procedures; export certification; import inspection; complete separation of official establishments; and official control over condemned material. Furthermore, supervisory IPP (i.e., PHVs) receive at least one in-plant performance review per year from the FSIS area supervisor to evaluate their performance in conducting and overseeing the performance of FSIS IPP in establishments. FSIS EIAOs also receive at least one in-person assessment per year from FSIS supervisory personnel to evaluate their performance in conducting food safety assessments, public health risk evaluations, recall effectiveness checks, and outreach activities. In addition to the in-plant performance reviews of FSIS IPP, FSIS also maintains a performance management system, as required in 5 U.S.C. 43, which identifies and sets performance expectations and monitors performance. All FSIS IPP receive a midyear progress review and an annual performance rating. FSIS IPP who do not receive an acceptable rating are put on a Performance Improvement Plan with clearly defined expectations and a timeline, and failure to improve can lead to reassignment or removal.

Instructions to FSIS supervisory personnel on how to conduct in-plant performance reviews are provided in FSIS Directive 4430.3 In-Plant Performance System (IPPS) and FSIS Directive 4430.5 Supervisory Tool for Assessment Results. Instructions to FSIS supervisory personnel on how to conduct in-person performance reviews for FSIS EIAOs are provided in FSIS Directive 4440.1 Enforcement Investigation and Analysis Officer Assessments.

14. How does the CCA ensure complete separation of certified meat, poultry, or eggs products from non-certified meat, poultry, or egg products? FSIS ensures complete separation of official from unofficial establishments by verifying compliance, during routine government verification activities and supervisory visits, with 9 CFR 305.2 (meat), 381.26 (poultry), and 533.1 (Siluriformes). These regulations require that official establishments be \u201cseparate and distinct\u201d from other establishments. When official establishments produce non-FSIS amenable product (e.g., product produced under the jurisdiction of the U.S. Food and Drug Administration (FDA)), FSIS IPP routinely verify that the FSIS amenable product is produced separately, by time or space, from the non-FSIS amenable product. In addition, FSIS IPP consult the Export Library to verify that establishments producing product for export are meeting the specific requirements of the importing country, including any requirements necessitating producing product for export separately from domestic product (e.g., product produced without antimicrobial rinses).

15. How does the CCA ensure that meat, poultry, and egg products intended for export to the U.S. meet U.S. labeling requirements?", "FSIS Responses to the SRT (v2019-001) 18 FSIS ensures that meat, poultry, and egg products produced for domestic commerce or export comply with the labeling requirements in 9 CFR 317 and 319 (livestock), 9 CFR 541 (Siluriformes), 9 CFR 381 subpart N (poultry), and 9 CFR 590.410- 590.419 (egg products). These regulations implement the statutory provisions in 21 U.S.C. 607 (meat), 457 (poultry), and 1036 (egg products). The FMIA and PPIA both require establishments to obtain prior approval for labels of meat and poultry products before the products enter commerce. Prior approval is granted in one of two ways: sketch approval which is approved by the FSIS Labeling and Program Delivery Staff (LPDS), or generic approval which is approved by FSIS IPP verifying compliance with 9 CFR 412.2. In addition, FSIS requires that establishments maintain records of all labeling (9 CFR 320.1(b)(11), 381.175(b)(6), 412.1, and 550), to include: the final label applied to the product; product formulation; processing procedures; and supporting documentation, including prior sketch approval from LPDS (if applicable). The labeling requirements for imported meat and poultry products are provided in 9 CFR 327.14 - 327.15 (meat), 381.204 - 381.206 (poultry), and 557.14 \u2013 557.15 (Siluriformes). For egg products establishments, 9 CFR 590.411 requires prior label approval for all egg products before the products enter commerce. Further, 9 CFR 590.950 and 590.955 list the labeling requirements for imported egg products. FSIS IPP perform routine labeling verification activities (i.e., no less than two labeling verification activities per week in meat and poultry establishments, and no less than one labeling verification activity per week in egg products establishments) to verify that all regulatory labeling requirements are being met and followed, and all labels are accurate and truthful. When performing the general labeling verification activity, FSIS IPP verify that the label contains all required information; the ingredients statement is accurate, (i.e., that all ingredients are listed in descending order of predominance); the label declares any proteinaceous substances used in the ingredients statement; the establishment used restricted ingredients as per regulatory requirements (e.g., sodium nitrite in bacon) the label is used on appropriate product; and a label approval is on file.

Further, during general labeling verification, FSIS IPP review a sample of labels generically approved by the establishment to determine compliance with generic labeling requirements (9 CFR 412.2). Instructions to FSIS IPP for performing the general labeling verification activity, including how and when to document noncompliance, are provided in FSIS Directive 7221.1 Prior Labeling Approval. Instructions to FSIS IPP for performing labeling verification activities on imported products are provided in FSIS Directive 9900.5 Label Verification of Imported Meat, Poultry, and Egg Products. In addition to verifying general labeling requirements, FSIS IPP also routinely verify that products are labeled with accurate net weights and not economically adulterated (9 CFR 442); and that labeled products meet regulatory standards through reviewing formulation records, or observing the preparation of products and comparing the findings to the appropriate regulatory standards (e.g., verifying that labeled products meet the standards of identity in 9 CFR 319 (meat) and 9 CFR 381 Subpart P (poultry)). Instructions to FSIS IPP on how to verify that products are labeled accurately and not economically adulterated (e.g., inaccurate net weight), including how and when to document noncompliance, are provided in FSIS Directive 7000.1, Verification of Non-Food Safety Consumer Protection Regulatory Requirements. FSIS IPP also verify that ingredients used in the production of meat, poultry, and egg products are safe and suitable and approved per 21 CFR. These approved ingredients are listed in FSIS Directive 7120.1 Safe and Suitable Ingredients used in the Production of Meat, Poultry, and Egg Products, and 9 CFR 424.21. In addition to routine labeling verification activities, FSIS IPP also perform a monthly verification activity to verify that establishments are accurately controlling and labeling the eight most common food allergens (i.e., wheat; crustacean shellfish (e.g., crab, lobster, shrimp); eggs; fish; peanuts; milk;,"FSIS Responses to the SRT (v2019-001) 19 tree nuts (e.g., almonds, pecans, walnuts); and soybeans). Instructions to FSIS IPP on how to perform this allergen verification activity, including how and when to document noncompliance, are provided in FSIS Directive 7230.1. If an establishment ships product into commerce containing an undeclared allergen, the product is considered adulterated and misbranded (as defined in 21 U.S.C. 601 (meat), 453 (poultry), or 1033 (egg products)), and the establishment is subject to enforcement actions per 9 CFR 500 (meat and poultry) or 9 CFR 590.160 (egg products). Instructions to FSIS personnel, such as FSIS OIEA compliance officers and FSIS OFO District Managers, on the methodology to use when deciding whether to implement administrative enforcement actions are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. Instructions to FSIS OIEA compliance officers on the procedures to follow when taking enforcement actions are provided in FSIS Directive 8010.5 Case Referral and Disposition. Lastly, FSIS conducts \u201cfor cause\u201d species verification testing on both domestic and imported product. Instructions to FSIS IPP on how to collect samples for species verification testing are provided in FSIS Directives 7000.1. Instructions to FSIS IPP on how to collect samples for species verification testing in domestic establishments producing Siluriformes products are provided in FSIS Directive 14,010.1 Speciation, Residue, and Salmonella Testing of Fish of the Order Siluriformes from Domestic Establishments, and instructions for collecting samples for species verification testing on imported Siluriformes products are provided in FSIS Directive 14,100.1 Speciation, Residue, and Salmonella Testing of Fish of the Order Siluriformes at Official Import Inspection Establishments.

16. How does the CCA ensure that meat and poultry products designated for export to the U.S. are not restricted by the USDA Animal and Plant Health Inspection Service

(APHIS)? FSIS ensures that its imported meat and poultry originate from regions not currently restricted by APHIS by only importing meat, poultry, and egg products from countries where FSIS has determined, through documentation review and an on-site audit that the country\u2019s food safety inspection system provides a level of sanitary protection equivalent to the level achieved by FSIS. Part of the equivalency process involves determining that the foreign country and establishments are not using source material from a currently restricted region (as identified on the APHIS website) to produce product for export to the U.S. Countries that fail to demonstrate that its source material is from an unrestricted region are deemed not equivalent and, thus, ineligible to export that commodity to the U.S. Furthermore, CBP verifies that the imported products are permitted entry into the U.S. and comply with USDA APHIS regulations prior to the products being received for FSIS reinspection. In addition, APHIS restrictions are programmed into PHIS and alert FSIS IPP if a shipment intended for importation is restricted by APHIS. During import reinspection, FSIS IPP verify that imported product originates from an eligible country with no current APHIS restrictions for that product, and if a violation or defect is observed upon reinspection, FSIS IPP document the finding in PHIS and refuse entry of the product. Instructions to FSIS IPP on how to identify, control, document, and dispose of imported meat, poultry, or egg products that are refused entry into the U.S. are provided in FSIS Directive 9900.8 Meat, Poultry, and Egg Products Refused Entry Into The United States (U.S.). Furthermore, FSIS IPP verify during ante-mortem inspection that animals presented for slaughter do not display symptoms of foreign animal diseases and reportable conditions. Instructions to FSIS IPP on the conditions to look for when suspecting an animal may have a foreign animal disease or reportable condition, including the actions to take when a condition is suspected (i.e., contact APHIS), are provided in FSIS Directive 6000.1

#### Responsibilities Related to Foreign Animal Diseases (FADs) and Reportable Conditions.

Jurisdiction over imported shell eggs is shared by FDA, APHIS, and USDA Agricultural Marketing Service (AMS). Each individual farm that produces shell eggs for export to the U.S. must register with FDA and comply with the regulatory requirements in 21 CFR 118. In addition, APHIS verifies that all", "FSIS Responses to the SRT (v2019-001) 20 imported agricultural products shipped to the U.S. from abroad, including shell eggs and egg products, meet APHIS entry requirements to exclude pests and diseases of agriculture. (Note: APHIS will allow for the importation of shell eggs from regions with Newcastle disease or Highly Pathogenic Avian influenza provided that the requirements in 9 CFR 94.6 are met (i.e., the shipment is accompanied by a certificate signed by an official veterinarian from that region, the eggs are moved under USDA seal directly from the port of arrival to an official breaking and pasteurization establishment)). Furthermore, AMS is responsible for checking imported shell eggs and ensuring that imported eggs originate from foreign farms registered with FDA. Further information can be found on the FSIS website under Sourcing Egg Products and Shell Eggs from Foreign Countries. 17. How does the CCA ensure that all beef products are free of infectious materials associated with bovine spongiform encephalopathy (BSE), and all small ruminants (i.e., sheep and goats) are free of infectious materials associated with transmissible spongiform encephalopathy (TSE)? FSIS ensures that all beef products are free of infectious materials associated with BSE by requiring and verifying that specified risk materials (SRMs) be removed from the carcasses of cattle, segregated from edible materials, and disposed of in accordance with the provisions in 9 CFR 314.1 or 9 CFR 314.3. 9 CFR 310.22 identifies the following

materials from cattle 30 months of age and older as SRMs: brain, skull, eyes, trigeminal ganglia, spinal cord, vertebral column (excluding the vertebrae of the tail, the transverse processes of the thoracic and lumbar vertebrae, and the wings of the sacrum), and dorsal root ganglia. In addition, the distal ileum of the small intestine and the tonsils are recognized as SRMs in cattle of all ages. Further, 9 CFR 310.22(d)(1) lists the conditions under which the small intestine from all cattle may be used for human food. 9 CFR 310.22 also identifies prescriptive procedures for the removal, segregation, and disposition of SRMs. Establishments that slaughter cattle and establishments that process the carcasses or parts of cattle are required to develop, implement, and maintain written procedures for the removal, segregation, and disposition of SRMs. Furthermore, these procedures must address potential contamination of edible materials with SRMs before, during, and after entry into the establishment, and be incorporated into the establishment\u2019s HACCP plan, Sanitation SOPs, or other prerequisite program. If either the establishment or FSIS determines that the establishment\u2019s SRM procedures failed to effectively remove, segregate, or dispose of SRM material, the establishment is required to take corrective actions. In addition, the establishment must maintain daily records sufficient to demonstrate adequate implementation and monitoring of the SRM procedures and any corrective actions taken. Lastly, 9 CFR 310.22 describes the sanitation requirements for equipment used to cut through SRMs. Instructions to FSIS IPP on how to verify the adequate removal, segregation, and disposition of SRMs, including instructions on documenting noncompliance and enforcement actions, are provided in FSIS Directive 6100.3 Ante-mortem and Post- mortem Poultry Inspection. In addition to FSIS IPP verifying the adequate removal, segregation, and disposition of SRMs through routine government in-plant verification activities, USDA APHIS administers a national BSE surveillance program where FSIS IPP collect and submit brain tissue samples from cattle condemned on ante-mortem inspection for central nervous system conditions. Instructions to FSIS IPP on how to collect and submit samples for this program are provided in FSIS Directive 10,400.1 Sample Collection from Cattle under the Bovine Spongiform Encephalopathy (BSE) Ongoing Surveillance Program. Lastly, FSIS does not require or verify the removal of SRMs from small ruminants because TSE has not been determined to be a public health risk in the U.S. USDA APHIS conducts a Scrapie Flock Certification Program to certify scrapie-free herds and a Scrapie Eradication Program to accelerate the eradication of scrapie from the U.S." , "FSIS Responses to the SRT (v2019-001) 21 18. How does the CCA ensure control over condemned animals, which can include portions of inspected carcasses and parts, and inedible material, until destroyed or otherwise denatured? The FMIA (21 U.S.C. 603, 604, 606, 641), PPIA (21 U.S.C. 455, 460), and EPIA (21 U.S.C. 1034(c), 1039) all contain provisions requiring control over condemned animals or inedible material until destroyed for food purposes in the presence of an inspector, or otherwise denatured. These statutory provisions are codified in 9 CFR 311 and 314 (meat), 381.95 (poultry), 540 (Siluriformes), and 590.422 (egg products). In addition, the requirements for denaturing products and acceptable denaturing procedures are provided in 9 CFR 325.11, 325.13 (meat), 381.95 (poultry), and 540.3 (Siluriformes). During both ante-mortem and post-mortem livestock and poultry inspection activities, FSIS IPP verify that adulterated and condemned materials are properly identified and controlled. FSIS IPP verify that any carcass or part affected with a disease or condition listed in 9 CFR 311 (meat) or 9 CFR 381.80381.94 (poultry) is disposed of in accordance with the requirements in 9 CFR 314 (meat) or 9 CFR

381.95 (poultry). Furthermore, FSIS IPP verify that SRM and inedible materials are properly identified, controlled, and disposed of, and that all inedible materials are denatured prior to leaving the establishment. During routine inspector verification of SPS requirements, FSIS IPP verify that establishments comply with 9 CFR 416.3(c), which requires that containers used for storing inedible material be clearly marked for that purpose and cannot be used for storing edible product. Additionally, FSIS maintains the authority and ability to suspend any establishment that fails to destroy a condemned meat or poultry carcass or its components (9 CFR 500.3). Regarding egg product establishments, FSIS IPP verify that eggs ineligible for breaking and adulterated egg products are condemned and destroyed for human food purposes under the supervision of an inspector (9 CFR 590.422); and that all loss or inedible eggs or egg products are placed in a container clearly labeled \u201cinedible,\u201d and sufficiently denatured per the requirement in 9 CFR 590.504(c). 19. How does the CCA ensure the implementation and maintenance of an egg products food safety inspection system that prevents food safety hazards that arise before, during, and after the intake of shell eggs for processing; and that only shell eggs determined to be fit for human food are used to produce processed egg products designated for export to the U.S.? FSIS\u2019s regulatory oversight of egg products establishments ensures that food safety hazards are being prevented before, during, and after receiving shell eggs for processing by providing continuous government inspection to verify compliance with the statutory provisions in the EPIA and all regulatory requirements in 9 CFR 590. Examples of regulatory requirements that FSIS IPP verify compliance with include operating requirements for the following: candling and transfer room facilities and equipment (9 CFR 590.506, 590.508); proper sorting and identification of shell eggs to ensure that ineligible eggs as listed in 590.510 are not used to produce FSIS-inspected egg products; washing shell eggs with a continuous cleaning method (9 CFR 590.515); sanitizing (with potable water containing 100-200 ppm of available chlorine) and drying prior to breaking ( 9 CFR 590.516); and breaking rooms, freezing rooms, defrosting tanks or vats, spray process and albumen flake process dryers, blending and packaging equipment, air flow filtration, and heat treatment rooms (9 CFR 590.520-590.548). In addition, FSIS IPP verify that liquid egg products are properly pasteurized per the minimum temperature and holding time requirements in 9 CFR 590.570, or are heat-treated per the methods in 9 CFR 590.575; and meet the minimum cooling and freezing temperature requirements listed in 9 CFR 590.530 and 590.536. FSIS IPP verify that only shell eggs determined to be fit for human food are used to produce FSIS-inspected egg products by verifying that shell eggs are properly classified and sorted so only eligible","FSIS Responses to the SRT (v2019-001) 22 eggs are presented for breaking (9 CFR 590.510). FSIS IPP follow instructions in FSIS Directive 5030.1 Inspection Methodology Utilizing the Public Health Information System (PHIS) for the Verification of Regulatory Compliance in Egg Products Plants to verify that egg products establishments are meeting all food safety regulatory requirements in 9 CFR 590, including the requirement that shell eggs, when presented for breaking, be of edible interior quality and the shell be sound and free of adhering dirt and foreign material (9 CFR 590.510(c)). Instructions to FSIS IPP on how to verify that egg products establishments meet all applicable regulatory requirements, including how and when to document noncompliance and take additional enforcement actions, are provided in FSIS Directive 5030.1 Inspection Methodology Utilizing the Public Health Information System (PHIS) for the Verification of Regulatory Compliance in Egg Products Plants . Additional instructions to

FSIS IPP on performing egg products verification activities are provided in FSIS Directives 5020.1 Verification Activities for the Use of New Technology in Meat and Poultry Establishments and Egg Products Plants, 5030.5 Review of Egg Products Plants Drawings and Specifications, and 5040.1 Uses of FSIS Form PY-200 Egg Products Inspection Certificate. Component 3

Government Sanitation Verification 20. How does the CCA ensure that Siluriformes fish and fish products are raised and transported under sanitary conditions? FSIS IPP verify that Siluriformes fish and fish products are raised and transported under sanitary conditions by verifying compliance with the regulatory requirements in 9 CFR 534. These requirements include, but are not limited to, ensuring that Siluriformes fish harvested for use as human food have grown and lived under conditions that will not render the Siluriformes fish or their products unsound, unwholesome, unhealthful, or otherwise unfit for human food (9 CFR 534.1); and vats or containers used to transport the Siluriformes fish from the producer to the processor are maintained in a sanitary condition (9 CFR 534.4). FSIS IPP verify compliance with the regulatory requirements in 9 CFR 534 during a weekly verification activity by reviewing establishment records pertaining to pre-harvest standards and transportation to the processing establishment, such as water quality records for ponds and other waters where the Siluriformes fish are harvested. After reviewing the establishment records, if FSIS IPP have concerns that the Siluriformes fish may have been raised under insanitary conditions that may lead to adulterated or unwholesome product (e.g., evidence of heavy metals, pesticides, fertilizers, industrial chemicals, or drugs), FSIS IPP perform a HACCP verification activity to verify whether the establishment took appropriate corrective actions according to its HACCP system, adequately addressed chemical hazards in its hazard analysis, and implemented controls for the identified chemical hazards. In addition, Siluriformes fish arriving at the establishment that are dead, dying, diseased, or contaminated with substances that may adulterate fish products, are condemned (NOTE: FSIS does not require that wildcaught Siluriformes fish that die on the way to the establishment be condemned unless they are in a diseased or spoiled state). Instructions to FSIS IPP on how to verify compliance with 9 CFR 534 are provided in FSIS Directive 14,000.1 Consumer Safety Inspector Responsibilities at Fish Establishments. Instructions to FSIS IPP on how to verify HACCP regulatory requirements are provided in FSIS Directive 5000.1 Verifying an Establishment\u2019s Food Safety System. Instructions to FSIS IPP on how to verify that establishments adequately address hazards in their HACCP system are provided in FSIS Directive 5000.6 Performance of the Hazard Analysis Verification (HAV) Task. Furthermore, if FSIS suspects that Siluriformes fish are being raised under insanitary conditions, 9 CFR 534.2 provides FSIS with the authority to collect samples of feed, fish, and water from producers for the purpose of verifying that the Siluriformes fish are being raised under conditions that will yield safe, wholesome products.", "FSIS Responses to the SRT (v2019-001) 23 Lastly, if an establishment produces and ships adulterated Siluriformes products, FSIS has the authority and ability to suspend or withdraw inspection per 9 CFR 500. Instructions to FSIS personnel, such as FSIS OIEA compliance officers and FSIS OFO District Managers, on the methodology to use when deciding whether to implement administrative enforcement actions are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. Instructions to FSIS OIEA compliance officers on the procedures to follow when taking enforcement actions are provided in FSIS Directive 8010.5 Case Referral and Disposition. 21. How does the CCA ensure that Siluriformes fish that have died from circumstances other than

under the controlled circumstances of commercial fishing are separated from eligible Siluriformes fish and fish products? FSIS IPP verify that Siluriformes fish that have died from circumstances other than under the controlled circumstances of commercial fishing are separated from eligible Siluriformes fish and fish products by verifying compliance with the regulatory requirements in 9 CFR 539.1 and 540.1. The types of conditions that would preclude a fish or fish part from being eligible for further processing include, but are not limited to, abscesses; lesions; parasites; flukes; spoilage or decomposition; and gross deformities caused by disease or chemical contamination. FSIS IPP verify compliance with the regulatory requirements in 9 CFR 539.1 and 540.1 during a monthly verification task by observing points in the process where the establishment examines whole fish and fish products for quality or acceptability (e.g., initial sorting of live fish; after evisceration of whole fish; or after the fillet, trim, and cutup processes). In addition, FSIS IPP verify establishment control for various conditions including, but not limited to, abscesses; sores; ulcers; evidence of spoilage or decomposition in whole fish or processed product; unusual gross deformities caused by disease or chemical contamination; and disease, spoilage or decomposition of dead fish arriving at the establishment. (NOTE: FSIS does not require that wildcaught Siluriformes fish that die on the way to the establishment be condemned unless they are in a diseased or spoiled state).

Instructions to FSIS IPP on how to verify compliance with the regulatory requirements in 9 CFR 539.1 and 540.1, including how and when to document noncompliance, are provided in FSIS Directive 14,000.1 Consumer Safety Inspector Responsibilities at Fish Establishments. Further, if an establishment produces and ships adulterated Siluriformes products, FSIS has the authority and ability to suspend or withdraw inspection per 9 CFR 500. Instructions to FSIS personnel, such as FSIS OIEA compliance officers and FSIS OFO District Managers, on the methodology to use when deciding whether to implement administrative enforcement actions are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. Instructions to FSIS OIEA compliance officers on the procedures to follow when taking enforcement actions are provided in FSIS Directive 8010.5 Case Referral and Disposition.

How does the CCA ensure that livestock and poultry are slaughtered and processed in a sanitary manner? FSIS ensures that livestock are slaughtered and processed in a sanitary manner by verifying that establishments implement adequate sanitary dressing and process control procedures to prevent carcass contamination and comply with the regulatory requirements in 9 CFR 310.3, 310.17(a), 310.18(a), 318.2(b) and (d), 318.4(b), 416, and 417. Furthermore, the presence of visible fecal material, ingesta, or milk on livestock carcasses or carcass parts is considered an adulterant by FSIS per 21 U.S.C. 601(m)(3). "FSIS Responses to the SRT (v2019-001) 24 FSIS utilizes a system wide approach and verifies that the design of the establishment\u2019s slaughter operation includes a means to measure how well the sanitary dressing and process control procedures accomplish this purpose, and that the establishment responds if the measure shows that carcasses are adulterated and exposed to food safety hazards. The requirements concerning sanitary dressing include, but are not limited to, the removal of lactating and diseased mammary glands in livestock (9 CFR 310.17(a)); handling livestock in a sanitary manner to prevent contamination with fecal material, urine, hair, bile, dirt, or foreign material (9 CFR 310.18(a)); and ensuring that all livestock products are available for government reinspection as often as necessary for FSIS IPP to verify that products are not adulterated or misbranded at the time they enter or leave establishments (9 CFR 318.2(b)). In

beef slaughter establishments , FSIS IPP perform a sanitary dressing verification activity at least once per month to verify that establishments are implementing effective sanitary dressing and process control procedures to prevent contamination of carcasses (as required per 310.18(a)), and properly applying decontamination and antimicrobial intervention treatments to carcasses and parts to address any contamination that may occur. FSIS IPP perform this monthly sanitary dressing verification activity prior to the carcass receiving final inspection. Furthermore, FSIS IPP verify that establishments are properly assessing any microbial testing results, including results for indicators of process control, at any point during slaughter and at subsequent trim fabrication and grinding operations. Examples of microorganisms used as indicators of process control in raw beef operations include Enterobacteriaceae, generic Escherichia coli (E. coli), E. coli O157:H7, non-O157 STECs, and Salmonella. Instructions to FSIS IPP on how to verify sanitary dressing and process control procedures in beef slaughter establishments, including how and when to document noncompliance, are provided in FSIS Directive 6410.1 Verifying Sanitary Dressing and Process Control Procedures in Slaughter Operations of Cattle of Any Age. In addition to the monthly sanitary dressing verification activity in beef slaughter establishments, FSIS IPP also perform weekly SPS verification activities to verify that establishments maintain sanitary conditions in compliance with 9 CFR 416.1-416.5. Furthermore, in livestock establishments that incorporate written sanitary dressing and process control procedures as part of their HACCP Plan, Sanitation SOP, Good Manufacturing Practices (GMP), or other pre-requisite programs, FSIS IPP perform routine HACCP and sanitation verification activities to verify that establishments are implementing and following their procedures as written. Instructions to FSIS IPP on how to verify compliance with HACCP, Sanitation SOP, and SPS requirements, including how and when to document noncompliance, are provided in FSIS Directive 5000.1 Verifying an Establishment\u2019s Food Safety System. Furthermore, offline FSIS IPP perform livestock zero tolerance verification activities at least once per shift in livestock slaughter establishments. This activity includes verifying that livestock carcasses are free of visible fecal material, ingesta, and milk at or immediately after the final rail and before the final wash; and head, cheek, and weasand meat are free of visible fecal material, ingesta, and milk at the end of the harvesting process (e.g., at the packaging step or when the product is placed into a container for storage). Additionally, FSIS IPP verify that establishments implement controls (i.e., Critical Control Points) to prevent contamination of carcasses with fecal contamination, ingesta, and milk. Instructions to FSIS IPP on how to perform the livestock zero tolerance verification activity, including how and when to document noncompliance, verify appropriate corrective actions (as required per 9 CFR 417.3), and take enforcement measures, are provided in FSIS Directive 6420.2 Verification of Procedures for Controlling Fecal Material, Ingesta, and Milk in Livestock Slaughter Operations and FSIS Directive 5000.1 Verifying an Establishment\u2019s Food Safety System. Regarding poultry establishments, 9 CFR 381.65(f) requires all establishments that slaughter poultry (other than ratites) to develop, implement, and maintain written procedures to ensure that poultry", "FSIS Responses to the SRT (v2019-001) 25 carcasses contaminated with visible fecal material do not enter the chiller (as fecal material on poultry carcasses entering the chiller is considered by FSIS to be an adulterant per 21 USC 453(g)(3)). 9 CFR 381.65(g) requires establishments that slaughter poultry (other than ratites) to develop, implement, and maintain written procedures to prevent contamination with enteric pathogens and feces throughout the slaughter process. 9

CFR 381.65(g) also requires poultry slaughter establishments to determine which microbial organisms will be effective in monitoring process control and implement their own sampling plans, specifically for enteric pathogens and indicators of fecal contamination (e.g., generic E. coli). Further, 9 CFR 381.65 (f) and 381.65(g) require poultry slaughter establishments to incorporate the above written procedures into their HACCP plan, Sanitation SOP, or other prerequisite program. Lastly, 9 CFR 381.145(b) requires that all poultry products be available for government reinspection as often as necessary for FSIS IPP to verify that the products are not adulterated or misbranded at the time they enter or leave official establishments (9 CFR 381.145(b)). In establishments operating under poultry inspection systems other than NPIS (e.g., traditional, streamlined inspection system (SIS), new line speed (NELS) inspection system), offline FSIS IPP perform zero tolerance verification activities to verify that establishments are preventing carcasses with fecal material from entering the chiller. This activity is performed at least two times per production line on each shift that poultry is slaughtered, and consists of selecting and examining 10 poultry carcasses after the final wash and before the chilling tank, to verify that the establishment complies with 9 CFR 381.65(f). In establishments operating under NPIS, the zero tolerance verification activity is performed at an increased frequency of at least 8 times per production line on each shift that poultry is slaughtered (i.e., at least once per hour, offline FSIS IPP select and examine 10 carcass samples prior to the chiller to verify compliance with 9 CFR 381.65(f)). FSIS IPP perform routine HACCP and sanitation verification activities to verify that poultry establishments are maintaining and implementing written procedures for preventing contamination with feces throughout the slaughter process. For example, if a poultry slaughter establishment produces giblets (i.e., edible livers, hearts, or gizzards) and maintains a procedure in its Sanitation SOP plan to prevent fecal contamination on giblets, FSIS IPP perform a sanitation verification activity to verify that the establishment is following its written procedures and giblets are free from fecal contamination. Instructions to offline FSIS IPP on how to verify poultry slaughter establishments maintain adequate procedures for preventing contamination with feces and enteric pathogens throughout the slaughter process, including how and when to document noncompliance, verify appropriate corrective actions (as required per 9 CFR 417.3), and take enforcement measures, are provided in FSIS Directive 6420.5 Verifying Poultry Slaughter Establishments Maintain Adequate Procedures for Preventing Contamination with Feces and Enteric Pathogens. Additional instructions to FSIS IPP on how to perform verification activities in establishments operating under NPIS, including how and when to document noncompliance, verify appropriate corrective actions (as required per 9 CFR 417.3), and take enforcement measures, are provided in FSIS Directive 6500.1 New Poultry Inspection System: Postmortem Inspection and Verification of Ready-To-Cook Requirement. Instructions to FSIS IPP on how to verify compliance with HACCP, Sanitation SOP, and SPS requirements, including how and when to document noncompliance, are provided in FSIS Directive 5000.1 Verifying an Establishment's Food Safety System. Lastly, FSIS has the authority under 9 CFR 500 to implement enforcement measures including, but not limited to, suspension of inspection if sanitary conditions are such that products in the establishment are or would be rendered adulterated (9 CFR 500.3), and withdrawal of inspection for failure to maintain sanitary conditions (9 CFR 500.6(d)). Instructions to FSIS personnel, such as FSIS OIEA compliance officers and FSIS OFO District Managers, on the methodology to use when deciding whether to implement administrative enforcement actions

are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. Instructions to FSIS OIEA compliance officers on the procedures to follow when taking enforcement actions are provided in FSIS Directive", "FSIS Responses to the SRT (v2019-001) 26 8010.5 Case Referral and Disposition. 23. How does the CCA ensure that the condition of certified establishments\u2019 construction, facilities, and equipment is adequate to prevent the contamination or adulteration of meat, poultry, or egg products designated for export to the U.S.? FSIS ensures that establishments\u2019 construction, facilities, and equipment are maintained in a sanitary manner to prevent the contamination or adulteration of meat, poultry, or egg products by FSIS IPP verifying compliance with the SPS requirements in 9 CFR 416.1-416.6 (meat and poultry), and the sanitation requirements in 9 CFR 590.500-590.575 (egg products) at least once per week. These regulations implement the statutory provisions in 21 U.S.C. 608 (meat), 456 (poultry), and 1035 (egg products), which require that all establishments maintain sanitary conditions in their premises, facilities, and equipment, or FSIS will refuse to provide inspection. Prior to granting a meat or poultry establishment Federal inspection, FSIS surveys each establishment to determine whether the construction and facilities of the establishment are in accordance with the SPS regulations (9 CFR 304.2 (meat), 381.20 (poultry), and 532.2 (Siluriformes). Once an establishment is granted Federal inspection, FSIS verifies ongoing compliance with these regulations through routine verification activities and on-site supervisory reviews. If FSIS determines that a meat or poultry establishment\u2019s construction and facilities are creating insanitary conditions, FSIS can take an enforcement action, such as a regulatory control action or suspension, per 9 CFR 500. Instructions to FSIS personnel on granting, refusing, suspending or withdrawing inspection are provided in FSIS Directive 5220.1 Granting or Refusing Inspection; Voluntary Suspending or Withdrawing Inspection; and Reinstating Inspection under PHIS. Instructions to FSIS personnel, such as FSIS OIEA compliance officers and FSIS OFO District Managers, on the methodology to use when deciding whether to implement administrative enforcement actions are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. Instructions to FSIS OIEA compliance officers on the procedures to follow when taking enforcement actions are provided in FSIS Directive 8010.5 Case Referral and Disposition. Examples of the SPS regulatory requirements that FSIS IPP verify compliance with include, but are not limited to, maintaining a pest management program; separate and distinct rooms for the handling and processing of edible and inedible products; adequate lighting and ventilation; a potable water supply with adequate pressure; and cleaning and sanitizing both food contact surfaces and non-food contact surfaces, as frequently as necessary, to prevent the creation of insanitary conditions and the adulteration of product (9 CFR 416.2-416.4). Instructions to FSIS IPP on how to verify compliance with the SPS regulatory requirements, including how and when to document noncompliance and how to verify appropriate establishment corrective actions after instances of noncompliance, are provided in FSIS Directive 5000.1 Verifying an Establishment's Food Safety System. Prior to receiving continuous government inspection in egg product establishments, the establishment must demonstrate compliance with the sanitation requirements in 9 CFR 590, including requirements for equipment and facilities (9 CFR 590.146). The regulatory requirements for facilities\u2019/sanitation in egg products establishments are provided in 9 CFR 590.500-590.575. Examples of these requirements include, but are not limited to, maintaining buildings in sound construction and good repair to

prevent the entrance of vermin; efficient drainage and plumbing; a potable water supply with adequate pressure; and separate and enclosed refuse rooms (9 CFR 590.500). Instructions to FSIS IPP on how to verify construction, facility, and equipment requirements in egg processing establishments, including how and when to document noncompliance, are provided in FSIS Directive 5030.1 Inspection Methodology Utilizing the Public Health Information System (PHIS) for the Verification of Regulatory Compliance in Egg Products Plants. Furthermore, FSIS maintains the authority and ability to suspend inspection at egg product establishments that fail to maintain their premises, facilities, and equipment in a "FSIS Responses to the SRT (v2019-001) 27 satisfactory state of repair (9 CFR 590.160). 24. How does the CCA ensure that certified establishments develop, implement, and maintain daily pre-operational and operational sanitation procedures sufficient to prevent the direct contamination or adulteration of meat, poultry, and egg products designated for export to the U.S.? FSIS ensures that each establishment develops, implements, and maintains daily pre-operational and operational sanitation procedures sufficient to prevent the direct contamination or adulteration of meat, poultry, and egg products by verifying compliance with the Sanitation SOP requirements in 9 CFR 416.11-416.17 (meat and poultry) and 9 CFR 537.1 (Siluriformes), and the sanitation requirements in 9 CFR 590.500-590.575 (egg products). These regulations implement the statutory provisions in 21 U.S.C. 608 (meat), 456 (poultry), 1035 (egg products), which require that all establishments comply with the sanitation regulations to prevent adulterated product from entering commerce, or FSIS will refuse to render inspection. Furthermore, these regulations were created with the enactment of the Pathogen Reduction; Hazard Analysis and Critical Control Point (PR/HACCP) Systems Final Rule (61 FR 38806) in 1996 which requires that each meat and poultry establishment develop and implement written Sanitation SOPs. As previously mentioned, meat and poultry establishments are required to develop written Sanitation SOPs prior to receiving Federal inspection (9 CFR 304.3 (meat), 381.22 (poultry), and 532.2 (Siluriformes)). Instructions to FSIS personnel on how to verify these regulatory requirements are met prior to granting Federal inspection, and how to refuse, suspend or withdraw inspection when the requirements are not met, are provided in FSIS Directive 5220.1 Granting or Refusing Inspection; Voluntary Suspending or Withdrawing Inspection; and Reinstating Inspection under PHIS. In addition, the regulatory requirement to develop, implement, and maintain written Sanitation SOPs is verified through both routine in-plant verification activities and on-site supervisory visits. During Sanitation SOP verification activities, FSIS IPP routinely perform both observational and recordkeeping verification activities (i.e., at least twice per week) to verify that establishments meet all the regulatory requirements in 9 CFR 416.11-416.17, such as, describing the procedures and frequencies of all Sanitation SOPs; identifying the establishment personnel responsible for the implementation and maintenance of the procedures; identifying pre-operational cleaning procedures to include the cleaning of food contact surfaces; performing corrective actions when the Sanitation SOPs failed to prevent direct contamination or adulteration of product; and maintaining daily records documenting the implementation and monitoring of the Sanitation SOPs, and any corrective actions taken. Instructions to FSIS IPP on how to perform both operational and pre-operational sanitation verification activities, including enforcement measures and how and when to document noncompliance, are provided in FSIS Directives 5000.1 Verifying an Establishment's

Food Safety System and 5000.4 Performing The PreOperational Sanitation Standard Operating Procedures Verification Task. FSIS Directive 5000.1 also provides instructions to FSIS IPP on how to verify that establishments meet all the requirements in 9 CFR 416.15 when taking corrective actions, including how and when to take a regulatory control action when the establishment does not comply with the corrective action requirements in 9 CFR 416.15. Furthermore, if a meat or poultry establishment fails to implement or maintain written Sanitation SOP\u2019s, FSIS has the authority and ability to suspend or withdraw inspection per 9 CFR 500. Instructions to FSIS personnel, such as FSIS OIEA compliance officers and FSIS OFO District Managers, on the methodology to use when deciding whether to implement administrative enforcement actions are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. Instructions to FSIS OIEA compliance officers on the procedures to follow when taking enforcement actions are provided in FSIS Directive 8010.5 Case Referral and Disposition. In addition to verification during routine in-plant sanitation verification activities, FSIS supervisory personnel conduct on-site visits to verify that FSIS IPP are adequately performing sanitation", "FSIS Responses to the SRT (v2019-001) 28 verification activities and the establishment in meeting the requirements in 9 CFR 416. Furthermore, FSIS EIAOs verify compliance with sanitation regulatory requirements during food safety assessments. During these assessments, EIAOs verify that the design and implementation of the establishment\u2019s Sanitation SOPs is adequate to prevent insanitary conditions and product adulteration. Instructions to FSIS EIAOs on how to perform this activity are described in FSIS Directive 5100.1 Enforcement, Investigations, and Analysis Officer (EIAO) Comprehensive Food Safety Assessment Methodology. Egg products establishments must also demonstrate compliance with sanitation requirements prior to receiving continuous government inspection (9 CFR 590.146). On-going compliance with the egg products sanitation regulations (9 CFR 590.500-590.575) is verified through both in-plant verification activities and on-site supervisory reviews. During government verification activities, FSIS IPP routinely perform both observational and recordkeeping verification activities to verify that the establishment is meeting all sanitation requirements. These requirements include cleaning and sanitizing utensils and equipment prior to operations, and maintaining equipment and utensils in clean and sanitary conditions during all processing operations (9 CFR 590.504(n)). Instructions to FSIS IPP on how to perform sanitation verification activities in egg products establishments, including how and when to document noncompliance and take enforcement measures, are provided in FSIS Directive 5030.1 Inspection Methodology Utilizing the Public Health Information System (PHIS) for the Verification of Regulatory Compliance in Egg Products Plants. In addition, if an egg products establishment fails to maintain sanitary conditions, FSIS has the authority and ability to refuse, suspend, or withdraw inspection per 9 CFR 590.160. Component 4 Government HACCP System Verification 25. How does the CCA ensure that certified establishments develop, implement, and maintain a HACCP system to ensure that food safety hazards are identified, and prevented or controlled when producing meat or poultry products for export to the U.S.? FSIS ensures that meat and poultry establishments identify food safety hazards and control identified food safety hazards by verifying compliance with all HACCP regulatory requirements in 9 CFR 417. These regulations were created with the enactment of the \u201cPathogen Reduction; Hazard Analysis and Critical Control Point (PR)\u201c/HACCP) Systems\u201d Final Rule (61 FR 38806) in 1996 which requires that all meat and poultry

establishments develop and implement a HACCP system for the purpose of reducing the occurrence and numbers of pathogenic microorganisms on meat and poultry products, and reducing the incidence of foodborne illness associated with the consumption of those products. Prior to receiving a grant of Federal inspection, or producing a new product for distribution in commerce, meat and poultry establishments are required to conduct a hazard analysis, and develop and validate a HACCP plan (if it is determined in the hazard analysis that one or more food safety hazards are likely to occur in the production process) as required by 9 CFR 304.3 (meat), 381.22 (poultry), and 532.2 (Siluriformes). In order to validate their HACCP plan under actual processing conditions, FSIS provides establishments seeking a grant of Federal inspection, or establishments producing new product, a 90-day conditional grant. Further, any establishment that produces product without a HACCP plan is subject to enforcement actions, such as suspension or withdrawal of inspection, per 9 CFR 500. Instructions to FSIS personnel on how to verify these regulatory requirements are met prior to granting Federal inspection, and how to refuse, suspend or withdraw inspection when the requirements are not met, are provided in FSIS Directive 5220.1 Granting or Refusing Inspection; Voluntary Suspending or Withdrawing Inspection; and Reinstating Inspection under PHIS. To verify regulatory compliance with all 9 CFR 417 requirements (and 9 CFR 537 requirements in establishments producing Siluriformes products), FSIS IPP routinely perform both observational and recordkeeping verification activities (i.e., at least twice per week per process category). During the "FSIS Responses to the SRT (v2019-001)" 29 observational and recordkeeping components of the HACCP verification activity, FSIS IPP verify that the establishment meets all HACCP regulatory requirements for all critical control points (CCP\u2019s), including monitoring, verification, recordkeeping, and corrective actions. These requirements include, but are not limited to, establishing critical limits; listing the procedures and frequencies used to monitor CCP\u2019s; performing and documenting on-going verification activities (i.e., the calibration of process monitoring instruments, direct observations of monitoring activities and corrective actions, and records review); maintaining CCP monitoring records that record the actual time, temperature, or other quantifiable value; reassessing the HACCP plan at least annually, or whenever any changes occur (e.g., a change in raw or source material, a change in product formulation); performing pre-shipment review; and developing and implementing corrective actions that will ensure that the cause of the deviation is identified and eliminated, the CCP will be under control after the corrective action is taken, measures to prevent recurrence are established, and no product that is injurious to health or otherwise adulterated as a result of the deviation enters commerce (9 CFR 417.2-417.5). Furthermore, when performing routine HACCP verification activities, FSIS IPP verify that establishments review all records associated with the HACCP system and tied to the specific production lot being shipped prior to signing the preshipment review record. This includes verifying that establishments receive acceptable establishment testing results (for establishment testing performed to support a decision made in the hazard analysis) and perform adequate corrective actions (9 CFR 417.3); and verifying that establishments receive and confirm acceptable official government testing results (from all official government samples taken from the specific production lot being shipped) prior to completing and signing the preshipment review record. As outlined in 76 FR 19955 \u201cNot Applying the Mark of Inspection Pending Certain Test Results\u201d, \u201cthe pre-shipment review of records associated with the production lot will not be complete without the pending

[official government] test results.\u201d This applies to confirmation of acceptable government verification testing results for the following sampled products: raw non-intact beef product or raw intact beef product intended for raw non-intact use that is tested for STEC; RTE products tested for Lm, Salmonella, or STEC (RTE beef products); RTE product that passed over food contact surfaces that have been tested for the presence of Lm and Salmonella; and livestock carcasses subject to FSIS testing for veterinary drugs (e.g., antibiotics, sulfonamides, avermectins). In addition to verification during routine in-plant HACCP verification activities, FSIS supervisory personnel also verify compliance with the HACCP requirements during supervisory visits. FSIS supervisory personnel conduct on-site visits to verify that FSIS IPP are adequately performing HACCP verification activities and the establishment in meeting the requirements in 9 CFR 417. Furthermore, FSIS EIAOs verify compliance with HACCP regulatory requirements during food safety assessments. During these assessments, EIAOs analyze and document whether the establishment\u2019s HACCP system has identified and prevented or controlled all hazards that are reasonable likely to occur in the production process, and whether the establishment maintains adequate supporting documentation to support its decisions regarding the identified hazards. Instructions to FSIS EIAOs on how to perform this analysis are described in FSIS Directive 5100.1 Enforcement, Investigations, and Analysis Officer (EIAO) Comprehensive Food Safety Assessment Methodology. Lastly, FSIS IPP perform quarterly hazard analysis verification activities in all establishments to verify that establishments have conducted a hazard analysis identifying all food safety hazards in their process, and implemented preventive measures to control these hazards. When performing the hazard analysis verification activity, FSIS IPP refer to the FSIS Meat and Poultry Hazards and Controls Guide, which lists potential biological, physical, and chemical hazards and frequently used controls and preventive measures for each step. FSIS IPP also verify that establishments maintain adequate support for all decisions made in their hazard analyses, including support for both CCPs and prerequisite programs. This also includes verifying that establishments maintain both components for HACCP validation: scientific and technical data, and in-plant (implementation) data." "FSIS Responses to the SRT (v2019-001) 30 Instructions to FSIS IPP on how to verify that an establishment is meeting all HACCP regulatory requirements and effectively implementing its HACCP plan, including how and when to document noncompliance and take enforcement measures, are provided in FSIS Directive 5000.1 Verifying an Establishment's Food Safety System. Instructions to FSIS IPP on how to verify that an establishment\u2019s hazard analysis meets all 9 CFR 417 regulatory requirements, including how and when to document noncompliance and take enforcement measures, are provided in FSIS Directives 5000.1 and 5000.6 Performance of the Hazard Analysis Verification (HAV) Task. Instructions to FSIS personnel, such as FSIS OIEA compliance officers and FSIS OFO District Managers, on the methodology to use when deciding whether to implement administrative enforcement actions are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. Instructions to FSIS OIEA compliance officers on the procedures to follow when taking enforcement actions are provided in FSIS Directive 8010.5 Case Referral and Disposition. Component 5 Government Chemical Residue Program 26. How does the CCA ensure the implementation and maintenance of an official government chemical residue control program that prevents and controls all specific compounds of concern in the foreign country and in the U.S.? FSIS considers meat, poultry, and egg products to be

adulterated under the FMIA (21 U.S.C. 601(m)(1)), PPIA (21 USC 453(g)(1)), and EPIA (21 USC 1033(a)(1)) if the product contains a chemical compound at a level in excess of an established tolerance or action level, or if the residue detected has no approved tolerance. Under the authority of the FMIA, PPIA, and EPIA, FSIS administers the U.S. National Residue Program (NRP) for Meat, Poultry, and Egg Products, which is an interagency program designed to identify, rank, and analyze for chemical contaminants in meat, poultry, and egg products. FSIS publishes the NRP Residue Sampling Plans (known as the Blue Book) each year to provide information on the process of sampling meat, poultry, and egg products for chemical contaminants of public health concern. The Blue Book includes information on FSIS\u2019s chemical residue sampling plans, a summary of changes from the previous year\u2019s NRP, and a list of chemical residues by class\method. The NRP is developed in consultation with the Surveillance Advisory Team (SAT) which is comprised of technical experts from the following three principal U.S. government agencies: FSIS, FDA, and the Environmental Protection Agency (EPA). The SAT meets annually to decide which compounds represent a public health concern and warrant inclusion in the NRP scheduled sampling plans. In addition, the SAT may propose, based on professional judgment and reliable field information, the initiation of exploratory assessments for directed sampling on a production class or region of the country. These agencies work together to create the annual sampling plan, based on the following: prior NRP findings of chemical residues in meat, poultry, and egg products; FDA veterinary drug inventories completed during on-farm visits and investigation information; and pesticides and environmental contaminants of current importance to EPA. FSIS\u2019s 2018 NRP includes an overview of domestic and import reinspection sampling plans, as well as the policy and procedures for holding or controlling product under the NRP. Chemical compounds analyzed in the program include approved and unapproved veterinary drugs, pesticides, and environmental compounds. The NRP is designed to: (1) provide a structured process for identifying and evaluating chemical compounds used in animal foods, (2) analyze chemical compounds of concern, (3) collect, analyze, and report results, and (4) identify the need for regulatory follow-up subsequent to the identification of violative levels of chemical residues.", "FSIS Responses to the SRT (v2019-001) 31 FSIS uses novel multi-residue methods for the detection and confirmation of veterinary drugs, pesticides, and environmental contaminants. Appendix I of the NRP lists the names of the chemical residues by class\method. The analytical methods used for screening and confirmation are provided in the FSIS Chemistry Laboratory Guidebook. Furthermore, the tolerances for veterinary drugs and action levels for environmental contaminants are established by FDA, and listed under Title 21 CFR. Tolerances for registered pesticides are established by the EPA, and listed under Title 40 CFR. The NRP consists of three separate, but interrelated, chemical residue testing programs: scheduled sampling (Tier 1), targeted sampling at the production or compound class level (Tier 2), and targeted sampling at the herd\flock or compound class level. The NRP also contains the number of analyses per production class by compound class, and the statistical basis for the sampling number (about 800 samples for each of the nine major production classes tested under Tier 1). Furthermore, FSIS laboratory personnel enter detailed residue violation information into an FSIS\FDA interagency database, and post a weekly Residue Repeat Violator\u2019s List on the FSIS website. When a violative result is identified, FSIS notifies the establishment, FSIS IPP, and the producer, of the analysis results. In addition, FSIS shares the violation data with EPA and FDA.

FDA has on-farm jurisdiction and works with cooperating State agencies to investigate producers linked to residue violations and, if conditions leading to residue violations are not corrected, can enforce legal action. FSIS IPP collect and submit official government chemical residue samples through either the scheduled (directed) sampling program or inspector generated sampling. Inspector generated sampling is conducted whenever FSIS IPP suspect, through either herd history or ante-mortem or post-mortem inspection findings, that a carcass may contain a violative residue finding (e.g., FSIS IPP observe mastitis or an injection site when performing ante-mortem inspection) or on any carcass exhibiting signs of systemic conditions (e.g., septicemia, peritonitis, pyemia). Inspector generated sampling is performed through an in-plant screening test known as the Kidney Inhibition Swab (KIS\u2122), which is an antibiotic screen test for kidney tissue; and through the collection and submission of tissue samples. Other examples of when inspector generated sampling is performed include, but are not limited to, when FSIS PHVs suspect nonsteroidal anti-inflammatory drugs (NSAID) or beta-agonist use in livestock. In addition, FSIS IPP also collect and submit samples for laboratory analyses on imported meat and poultry products. When a KIS\u2122 test and any other inspector-generated sampling is performed, FSIS IPP maintain control of the carcass and its parts pending non-violative test results. If a KIS\u2122 test is positive, FSIS IPP send liver, muscle, and kidney tissue to the laboratory for further analysis. Under the directed sampling program, FSIS IPP send kidney, liver, and muscle tissues to the laboratory for analysis; and verify the appropriate disposition of the livestock carcass pending violative test results.

Directed samples are assigned to FSIS IPP through PHIS based on the frequency noted in the NRP. Instructions to FSIS IPP on how and when to collect and submit residue samples; retain livestock carcasses pending non-violative test results (for samples taken under the inspector generated sampling program) or verify establishments are retaining carcasses pending nonviolative test results (for samples taken under the inspector generated sampling program); verify corrective actions; document noncompliance; and take enforcement actions are provided in FSIS Directive 10,800.1, Residue Sampling, Testing and Other Verification Procedures under the National Residue Program for Meat and Poultry Products and FSIS Directive 14,010.1 Speciation, Residue, and Salmonella Testing of Fish of the Order Siluriformes from Domestic Establishments. Instructions to FSIS IPP on how to collect KIS\u2122 samples are provided in KISTM Test Instructions. Lastly, instructions to FSIS IPP on how to collect and submit residue samples for imported meat, poultry, and egg products are provided in FSIS Directive 9900.6 and FSIS Directive 14,100.1 Speciation, Residue, and Salmonella Testing of Fish of the Order Siluriformes at Official Import Inspection Establishments. In addition, FSIS IPP withhold the mark of inspection on all livestock carcasses subject to FSIS testing (e.g., veterinary drugs, such as antibiotics, sulfonamides, or avermectins or the feed additive carbadox) pending non-violative testing results (77 FR 73401); and verify that establishments maintain control of "FSIS Responses to the SRT (v2019-001) 32 the livestock carcasses and parts and not allow those carcasses and parts to enter commerce until receipt and confirmation of non-violative official government testing results (76 FR 19955). If an establishment does not maintain control of a livestock carcass tested by FSIS for chemical residues (under the directed sampling program) and found to be violative, and the product enters commerce, FSIS has the authority and ability to take additional enforcement measures per 9 CFR 500. Accompanying the NRP is a detailed spreadsheet of the previous year\u2019s residue sampling results (known as the Red Book).

This sheet provides detailed information regarding samples taken by FSIS for both the domestic scheduled and inspector-generated sampling programs, in addition to the import sampling program results. The detailed results include sample collection and review dates, the project code, the animal class, tissue type, chemical residue name, concentration value, sample results (whether positive non-violative or positive violative), chemical concentration values (if any) and the CFR reference per chemical listed in the data sheet. Further information on FSIS\u2019s NRP, including a link to the Residue Repeat Violator\u2019s List and Residue Quarterly Reports, can be found under Residue Chemistry on the FSIS website. Component 6 Government Microbiological Pathogen and Process Control Programs 27. How does the CCA ensure that a slaughter establishment\u2019s microbiological sampling and testing program for meat and poultry verifies process control using microbiological analyses for indicators of intestinal and fecal contamination? Under \u201cPathogen Reduction; Hazard Analysis and Critical Control Point (PR)\u201c(HACCP) Systems\u201d (61 FR 38806), FSIS requires that slaughter establishments conduct routine microbiological testing to verify the adequacy of their slaughter and sanitary dressing process controls for the prevention of contamination with fecal material and other intestinal contents and associated bacteria. In livestock and ratite slaughter establishments, establishment testing for generic E.coli as an indicator organism allows the establishment to assess process capability and process control. More recently, FSIS implemented \u201cModernization of Poultry Slaughter Inspection\u201d (79 FR 49566) which specifies the requirements for how poultry slaughter establishments (excluding ratites) are to monitor process control through analyses for microbiological organisms, including sampling location and sampling frequency requirements. Requirements for process control verification criteria and testing can be found in 9 CFR 310.25 (meat), 381.65(g) (poultry) and 381.94 (ratites). 9 CFR 310.25 requires that all livestock slaughter establishments test for generic E.coli, and provides the sampling techniques, methodology, and frequency requirements for testing. These requirements include, developing and maintaining written specimen collection procedures that identify the employees designated to collect samples, the locations of sampling, how randomness is achieved, and measures to ensure sample integrity. Sample collection procedures include sponging or excising tissue from the flank, brisket, and rump for cattle (excluding hide-on calves); and sponging or excising tissue from the ham, belly, and jowl areas for swine. Further, this regulation requires that establishments analyze results using an Association of Official Analytical Chemists (AOAC) approved quantitative method or equivalent method, and maintain records of the analytic results (to be made available for FSIS review). FSIS IPP perform a weekly verification activity to verify that establishments implement effective control measures for relevant pathogens by reviewing establishment records for trend analysis of testing results and for responses to deviations resulting in food safety hazards. In addition, FSIS IPP perform routine verification activities to verify that establishments are implementing adequate control measures through either their HACCP system, Sanitation SOP\u2019s, or other prerequisite programs to control pathogens (e.g., antimicrobial intervention, sanitary dressing). Furthermore, FSIS IPP supervisory personnel verify that establishments maintain adequate control measures for relevant microbiological pathogens during supervisory reviews. Instructions to FSIS IPP on how to verify compliance with the "FSIS Responses to the SRT (v2019-001) 33 regulatory requirements in 9 CFR 310.25, including how and when to document noncompliance and how to identify trends of noncompliance, are provided in FSIS Directive

5000.1 Verifying an Establishment\u2019s Food Safety System. Instructions to FSIS IPP on how to review establishment testing data are provided in FSIS Directive 5000.2 Review of Establishment Data by Inspection Personnel. Additionally, 9 CFR 381.65(g) requires that all official poultry establishments (except those that slaughter ratites) develop, implement, and maintain written procedures to prevent contamination of carcasses and parts by enteric pathogens (e.g., *Salmonella* and *Campylobacter*) and fecal material throughout the entire slaughter and dressing operation. At a minimum, these procedures must include sampling and analysis for microbial organisms. Further, each establishment must incorporate these written procedures, including their microbiological sampling plans, into their HACCP plan, Sanitation SOPs, or other prerequisite programs; and maintain daily records documenting the implementation and monitoring of these procedures (also required to be made available for FSIS review). This regulation also specifies that samples are to be collected and analyzed for microbial organisms at the pre-chill and post-chill points in the process (unless a very small or very low volume establishment operating under Traditional Inspection), and that the required sampling frequency is proportional to the establishment\u2019s production volume (e.g., once per 22,000 carcasses for chicken, once per 3,000 carcasses for turkeys, ducks, geese, guineas, and squabs). Instructions to FSIS IPP on how to verify compliance with the regulatory requirements in 9 CFR 381.65(g), including how and when to document noncompliance, are provided in FSIS Directives 5000.1 Verifying an Establishment\u2019s Food Safety System and 6420.5 Verifying Poultry Slaughter Establishments Maintain Adequate Procedures for Preventing Contamination with Feces and Enteric Pathogens. Official establishments that slaughter ratites must also test for generic *E. coli* (9 CFR 381.94). These requirements mirror the requirements for generic *E. coli* testing in livestock establishments. Lastly, if a meat, poultry, or ratite establishment fails to meet the regulatory requirements in 9 CFR 310.25, 381.65(g), or 381.94, FSIS can take enforcement actions per 9 CFR 500, including suspension or withdrawal of inspection.

28. How does the CCA ensure the reduction of *Salmonella* in raw meat and poultry products, and *Campylobacter* in raw poultry products through sampling and other verification activities? FSIS ensures that raw meat and poultry products are produced safely and that pathogen levels are reduced or eliminated during slaughter and processing operations by implementing official government sampling and testing programs (i.e., routine, follow-up, and import sampling) for *Salmonella* and *Campylobacter* and performing non-sampling government verification activities (i.e., HACCP, Sanitation SOP, sanitary dressing verification) in establishments. FSIS IPP perform routine HACCP, Sanitation SOP, and sanitary dressing verification activities in all raw meat and poultry establishments to determine whether an establishment has procedures in place designed to address the control or monitoring of *Salmonella* or *Campylobacter* (e.g., interventions to reduce or eliminate *Salmonella* or *Campylobacter*, pre-harvest practices or purchase specification programs intended to reduce *Salmonella* or *Campylobacter* in live animals or raw materials received at the establishment). FSIS IPP also perform quarterly hazard analysis verification activities to verify that establishments are identifying and adequately addressing *Salmonella* and *Campylobacter* in their hazard analyses. In addition, FSIS IPP review establishment testing data and results at least once per production week for trend analysis. When reviewing establishment testing data, FSIS IPP verify that establishments perform adequate corrective actions in response to positive establishment testing results. Further, FSIS IPP in official poultry establishments verify that

establishments meet the chilling performance standards in 9 CFR 381.66(b) for poultry (excluding ratites) which include, chilling all poultry carcasses, parts, and giblets immediately after slaughter operations to prevent pathogen outgrowth (9 CFR 381.66(b)(1)(i)); and developing, implementing, and maintaining written procedures", "FSIS Responses to the SRT (v2019-001) 34 for chilling that addresses the potential for pathogen outgrowth, the conditions affecting carcass chilling, and the length of time necessary for adequate chilling (9 CFR 381.66(b)(3)). These procedures are required to be incorporated into the establishment\u2019s HACCP plan, Sanitation SOPs, or other prerequisite programs. In addition, 9 CFR 381.91(b)(1) and 381.91(b)(2) contain requirements for online and offline poultry reprocessing and require official establishments to incorporate procedures for the use of approved online antimicrobial intervention systems or offline reprocessing into their HACCP plans, Sanitation SOPs, or other prerequisite programs (see List of Approved On Line Reprocessing (OLR) and Off Line Reprocessing (OFLR) List of Approved On Line Reprocessing (OLR) and Off Line Reprocessing (OFLR) Antimicrobial Systems for Poultry). Instructions to FSIS IPP on how to verify establishment Salmonella and Campylobacter control programs are provided in FSIS Directive 10,250.1 Salmonella and Campylobacter Verification Program for Raw Meat and Poultry Products. Instructions to FSIS IPP on how to verify compliance with HACCP and sanitation regulatory requirements, including how and when to document noncompliance and take enforcement measures, are provided in FSIS Directive 5000.1 Verifying an Establishment\u2019s Food Safety System. Instructions to FSIS IPP on how to review establishment testing data are provided in FSIS Directive 5000.2 Review of Establishment Data by Inspection Personnel. The FSIS Salmonella sampling verification program formally began with the issuance of FSIS\u2019s final rule, \u201cPathogen Reduction; Hazard Analysis and Critical Control Point (PR)\u201c/HACCP) Systems\u201d (61 FR 38805-38989), published on July 25, 2006. Among other things, the PR\u201c/HACCP rule set Salmonella performance standards for establishments producing selected classes of raw meat and poultry products. As stated in the PR\u201c/HACCP rule (at 61 FR 38835), FSIS selected Salmonella for the performance standard because it is the most common cause of foodborne illness associated with meat and poultry products; it is present to varying degrees in all major species; and the interventions targeted at reducing Salmonella may help reduce contamination by other enteric pathogens. FSIS continues to use pathogen reduction performance standards to ensure that eligible establishments are consistently controlling or reducing harmful bacteria on raw meat and poultry products. FSIS has pathogen reduction performance standards listed in 9 CFR for the following products and is currently enforcing compliance with these performance standards: \u2022 Raw chicken and turkey o Carcasses (76 FR 15282) o Chicken parts (81 FR 7285)5 o Comminated products (81 FR 7285)6 FSIS has pathogen reduction performance standards listed in 9 CFR for the following products; however, these performance standards are not currently enforced by FSIS (see additional information below for information on why FSIS suspended its official government sampling verification program for these products): \u2022 Raw bovine products (9 CFR 310.25) o Steer and heifer carcasses o Cow and bull carcasses o Ground beef, bulk or patties \u2022 Market hog carcasses (9 CFR 310.25) To that end, FSIS has implemented official government sampling verification programs for Salmonella and Campylobacter in the following raw poultry products: chicken carcasses, turkey carcasses, chicken 5 On November 9, 2018, FSIS published Federal Register Notice \u201cChanges to the Salmonella and Campylobacter Verification

Testing Program: Revised Categorization and Follow-Up Sampling Procedure\u201d (83 FR 56046) 6 See Footnote 5","FSIS Responses to the SRT (v2019-001) 35 parts (e.g., legs, breasts, wings), comminuted chicken (i.e., product that has been ground, or hand- or mechanically deboned and further chopped, flaked, minced or otherwise processed to reduce particle size), and comminuted turkey. For clarification, \u201ccominuted\u201d means product that is ground, flaked, minced, or otherwise significantly reduced in particle size to less than \u00be inch (1.9 cm)). FSIS also tests the following raw beef products for Salmonella: raw ground beef, bench trim (purchased) and manufacturing trimmings, and other raw ground beef components such as head meat, cheek meat, weasand meat, heart meat, and product from advanced meat recovery systems (AMR). The methods for developing the pathogen reduction performance standards and predictions for the public health effect of those standards are described in the 2015 Public Health Effects of Raw Chicken Parts and Comminuted Chicken and Turkey Performance Standards. FSIS used the same methodology to estimate the public health effects for the chicken and turkey carcass performance standards in 2011. FSIS used a common analytical framework to estimate the improvements in public health (illnesses averted) associated with six separate pathogen reduction performance standards discussed as options. Based on the risk assessment predictions, FSIS estimated the reductions in salmonellosis and campylobacteriosis cases that would result if establishments made changes in their processes. Do note, in August 2018, FSIS began using an enrichment-based method to analyze poultry samples for Campylobacter due to the low sensitivity of the direct plating analytical method. Therefore, at this time, FSIS is not currently assessing Campylobacter performance in poultry establishments and is currently revising the Campylobacter performance standards based on the enrichment method. Regarding official government verification sampling for Salmonella in raw beef and swine, FSIS suspended official government verification of compliance with the Salmonella performance standards in beef (steers\heifers and cows\bulls) and swine (market hog) carcasses (2011), as well as in raw ground beef (2014), because the percentage of positive findings was very low. However, regulatory requirements in 9 CFR 310.25 remain in place for cow\bull\steer\heifer and market swine, and establishments that slaughter these livestock are expected to meet these criteria. Although these official government sampling verifications programs were suspended, FSIS continues to monitor the reduction of Salmonella by co-analyzing official government samples of raw ground beef, beef manufacturing trimmings, bench trim, and other raw ground beef components collected for STEC analysis for the presence of Salmonella (see 79 FR 32436, \u201cChanges to Salmonella Verification Sampling Program: Analysis of Raw Beef for Shiga Toxin-Producing Escherichia coli and Salmonella\u201d). In addition, FSIS samples raw ground beef products at retail stores, and imported ground beef, trim, and other raw ground beef components for Salmonella. For raw pork products, FSIS has initiated sampling and analysis of raw pork cuts and raw comminuted pork to determine the prevalence of Salmonella in these products (Raw Pork Products Exploratory Sampling Program). FSIS will use the data collected from these raw beef and pork products sampling programs to support future policy development, which could include new or updated Salmonella performance standards. In addition, FSIS has initiated sampling and analysis of raw Siluriformes fish products to determine the prevalence of Salmonella in these products to inform future policy development. The frequency of routine government verification sample assignment is dependent on slaughter volume data (e.g., higher volume-

producing establishments are sampled more frequently (maximum 4-5 samples per month per product type) than lower volume-producing establishments (minimum 1 sample\month per product type)). Additional information can be found in FSIS Establishment Eligibility Criteria for the Salmonella and Campylobacter Verification Sampling Program and FSIS Scheduling Algorithm for the Salmonella and Campylobacter Verification Sampling Programs for Raw Poultry. Instructions to FSIS IPP on how to choose and collect carcass\parts rinses (chicken) and carcass sponge (turkey) samples for Salmonella and Campylobacter testing, and the actions to take in the event an establishment fails to meet FSIS performance standard criteria (i.e., follow-up sampling) are provided in FSIS Directive 10,250.1 Salmonella and Campylobacter Verification Program for Raw", "FSIS Responses to the SRT (v2019-001) 36 Meat and Poultry Products. Additional information and instructions to FSIS IPP can be found under the Raw Chicken Parts Sampling Program and Raw Chicken Parts Sampling Supplies and \u201cHow to\u201d Guidance; and the Not Ready-to-Eat Commminated Poultry Sampling Program and Commminated Poultry Sampling Supplies and \u201cHow-to\u201d Guidance. In addition, FSIS monitors relevant databases (e.g., those maintained by the Centers for Disease Control and Prevention and the National Institutes of Health) for clinical isolates that match food isolates obtained by FSIS in its sampling of products produced by official establishments. When not ready-to-eat (NRTE) poultry or meat products are associated with an illness outbreak and contain pathogens that are not considered adulterants, FSIS likely will consider the product linked to the illness outbreak to be adulterated under 21 U.S.C. 453(g)(3) or 21 U.S.C. 601(m)(3) because the product is \u2018unsound, unhealthful, unwholesome, or otherwise unfit for human food.\u2019 In such cases, FSIS would request that the establishment recall the product if it is still in commerce. FSIS may also perform follow-up sampling and conduct a public health risk evaluation, to analyze the establishment\u2019s food safety system and determine if a food safety assessment is necessary. If deemed necessary, FSIS will schedule a food safety assessment (FSA) and verify whether the establishment is able to produce safe and wholesome poultry products in accordance with FSIS statutory and regulatory requirements. During the FSA, FSIS EIAOs review the establishment\u2019s food safety system as a whole, including the design of the establishment\u2019s HACCP system, supporting documentation for decisions made in the hazard analysis (e.g., validation documents), the design and implementation of the establishment\u2019s sampling and testing programs, and the establishment\u2019s reaction to sampling results. Instructions to FSIS EIAOs on how to conduct public health risk evaluations and perform food safety assessments are provided in FSIS Directive 5100.4 Enforcement, Investigations and Analysis Officer (EIAO) Public Health Risk Evaluation (PHRE) Methodology and FSIS Directive 5100.1 Enforcement, Investigations, and Analysis Officer (EIAO) Comprehensive Food Safety Assessment Methodology. FSIS\u2019s methods of analysis for official government Salmonella and Campylobacter verification testing programs are included in the MLG (Chapter 4 and Chapter 41, respectively). The proposed number of Salmonella (and Campylobacter in poultry) official government verification samples for raw beef and raw poultry products for the 2017 fiscal year (FY17), the actual number of samples for FY17, and the proposed number of samples for the FY18 can be found in the FSIS Annual Sampling Program Plan. Information on FSIS\u2019s Salmonella and Campylobacter sampling program for imported products can also be found in the FSIS Annual Sampling Program Plan. Lastly, additional information on FSIS\u2019s Salmonella and Campylobacter

verification testing program for raw meat and poultry, including monthly, quarterly, and annual reports, can be found under Microbiology on the FSIS website.

29. How does the CCA ensure through sampling and other verification activities that raw beef products are free of STEC at the end of the production process? FSIS considers all raw non-intact beef and raw intact beef intended for use in raw non-intact product to be adulterated under the FMIA (21 U.S.C. 601(m)(1)) if contaminated with E. coli O157:H7 or one of six non-O157 STEC (O26, O45, O103, O111, O121, and O145). To ensure that raw beef products are free of STEC, FSIS implements official government verification sampling and testing programs (i.e., routine, follow-up, and import sampling) and performs routine non-sampling government verification activities (i.e., HACCP, Sanitation SOP, sanitary dressing verification). FSIS IPP conduct routine HACCP verification activities, through review of records and observations, and a quarterly hazard analysis verification activity to verify that the establishment is meeting all 9 CFR 417 PR\HACCP regulatory requirements including, identifying STEC as a hazard in the hazard analysis; maintaining support for decisions made in the hazard analysis and HACCP plan, including prerequisite programs; adequately validating their HACCP plan; reassessment; and conducting monitoring, "FSIS Responses to the SRT (v2019-001) 37 verification, recordkeeping, corrective actions, and preshipment review per the regulatory requirements. FSIS IPP also verify that establishments identify the product\u2019s intended use (e.g., intact beef primal and subprimal cuts are intended for intact use) per the requirement in 9 CFR 417.2(a)(2) and have supporting documentation to support the product\u2019s intended use per 9 CFR 417.5(a)(1). FSIS IPP verify that establishments and retail stores that grind raw beef for sale in commerce maintain specific information about their grinding activities as required per 9 CFR 320.1(b)(4). Furthermore, FSIS IPP verify that establishments perform ongoing verification activities to ensure their food safety system is functioning as intended and continues to support decisions made in their hazard analysis, such as conducting establishment testing for STEC on an ongoing basis to demonstrate that their HACCP systems are working effectively to eliminate or reduce STEC to a non-detectable level. FSIS IPP review establishment testing data and results at least once per production week for trend analysis. When reviewing establishment testing data, FSIS IPP verify that establishments that received positive STEC results from their establishment testing program identify the sampled lot as adulterated per 21 USC 601(m)(1) and perform adequate corrective actions per 9 CFR 417.3. If an establishment fails to perform adequate corrective actions on product that tested positive for STEC (through establishment testing), and the product is shipped into commerce, FSIS can take enforcement actions per 9 CFR 500. Instructions to FSIS IPP on how to perform inspection verification activities other than official government verification sampling (e.g., HACCP verification), including how and when to document noncompliance and take enforcement measures, are provided in FSIS Directive 10,010.2 Verification Activities for Shiga Toxin-Producing Escherichia Coli (STEC) in Raw Beef Products. Instructions to FSIS IPP on how to review establishment testing data are provided in FSIS Directive 5000.2 Review of Establishment Data by Inspection Personnel. Instructions to FSIS IPP on how to verify whether official establishments are maintaining required records concerning suppliers and source materials for raw beef ground at the establishment are provided in FSIS Directive 5000.10 Verifying that Records are Kept by Official Establishments that Grind Beef. In addition to inspection verification activities, FSIS conducts official government verification sampling of raw ground beef products and raw intact beef products

intended for non-intact use, or when the intended use is unclear as described in FSIS Directive 10.010.1 Sampling Verification Activities for Shiga Toxin-Producing Escherichia Coli (STEC) in Raw Beef Products. FSIS collects and analyzes raw beef samples for both E. coli O157:H7 and Salmonella under four routine sampling programs which are categorized based on the product group (i.e., beef manufacturing trimmings; bench trim; other raw ground beef components, such as head meat, cheek meat, weasand meat, heart meat and product from advanced meat recovery systems (AMR); and raw ground beef products in establishments that grind or form patties). Beef manufacturing trimmings are also analyzed for presence of the six non-O157 STECs (i.e., O26, O45, O103, O111, O121, and O145), in addition to E. coli O157:H7 and Salmonella. These product samples are collected and submitted by FSIS IPP under the STEC sampling program. FSIS bases the frequency of its domestic sampling program primarily on production volume for each product group. The proposed number of official government verification samples for STEC in raw non-intact beef and raw intact beef intended for use in raw non-intact product for the 2017 fiscal year (FY17), the actual number of samples collected and analyzed for FY17, and the proposed number of samples for the FY18 can be found in the FSIS Annual Sampling Program Plan. Information on FSIS\u2019s STEC sampling program for imported beef products can also be found in the FSIS Annual Sampling Program Plan.

FSIS\u2019s methods of analysis for official Salmonella and STEC verification testing programs are included in the MLG (Chapter 4 and Chapter 5C respectively). Instructions to FSIS IPP on how to collect and submit official government STEC samples, including the actions to take when a test result is positive for STEC, are provided in FSIS Directive 10.010.1 Sampling Verification Activities for Shiga ToxinProducing Escherichia Coli (STEC) in Raw Beef Products . FSIS requires establishments to hold or maintain control of raw beef products that FSIS has tested for STEC pending negative FSIS results (76 FR 19955). In addition, FSIS IPP verify that establishments maintain a supportable basis for their lotting definition. For sampling purposes, lots should be defined","FSIS Responses to the SRT (v2019-001) 38 so that they are microbiologically independent; meaning that if a positive result is found in one lot, the product from the other lot would not be implicated. Factors that FSIS IPP look for when determining if the lot is microbiologically independent include, scientific, statistically-based sampling programs for STEC used to distinguish between segments of production; Sanitation SOP\u2019s or other prerequisite programs used to control the spread of STEC cross-contamination between raw beef components during production; co-mingling of products; and processing interventions that limit or control STEC contamination. Product that is implicated with a positive official government test result (i.e., product that is not microbiologically independent from the sample) and was not held would be subject to voluntary recall. 76 FR 19955 stipulates that if the establishment has completed preshipment review prior to receiving official government test results, and the official government test results are positive, the establishment has produced and shipped adulterated product into commerce (21 USC 601(m)(1)). Under these circumstances, FSIS will take an appropriate enforcement action per 9 CFR 500 (e.g., immediately suspending inspection or issuing a Notice of Intended Enforcement Action). In addition, FSIS will request a voluntary recall of product, detain the product in commerce, or institute other product control actions if necessary. Instructions to FSIS IPP on how to verify that establishments hold or retain control of product pending negative FSIS test results for STEC, and maintain support for lot definitions are provided in FSIS Directive 10,010.1 Sampling

Verification Activities for Shiga ToxinProducing Escherichia Coli (STEC) in Raw Beef Products.

When a routine official government verification sample tests positive for STEC, the sampled lot is considered adulterated as per the statutory definition in 21 U.S.C. 601(m)(1). FSIS IPP conduct followup sampling and perform HACCP, Sanitation SOP, and sanitary dressing verification activities, in both the producing and supplying establishments, to determine whether the establishments effectively address control of STEC and implement corrective actions per 9 CFR 417.3. Instructions to FSIS IPP on how to perform follow-up sampling when an official government test result is positive for STEC are provided in FSIS Directive 10,010.1 Sampling Verification Activities for Shiga Toxin-Producing Escherichia Coli (STEC) in Raw Beef Products. In addition, when a routine official government sample tests positive for STEC, FSIS EIAOs perform traceback investigations to verify all source materials and potential suppliers of source materials were identified, and any products not microbiologically independent from the adulterated lot are removed from commerce (when applicable). As part of traceback investigations, FSIS IPP review slaughter establishment test results to determine whether the establishment has experienced a high-event period. A high-event period is a high rate of positive STEC sample results over a relatively short period of time, indicating the establishment did not maintain adequate process control over STEC. FSIS IPP use this information to determine whether the establishment has a supportable basis for microbiological independence and can support its decision concerning which products are held from entering commerce. Instructions to FSIS personnel on how to perform traceback investigations, and determine whether the establishment has experienced a high-event period, are provided in FSIS Directive 10,010.3 Traceback Methodology for Escherichia Coli (E. coli) O157:H7 in Raw Ground Beef Products and Bench Trim. Furthermore, if an official government test result is confirmed positive for STEC, FSIS will conduct a public health risk evaluation to assess and analyze the establishment\u2019s food safety system and determine if an immediate enforcement action or food safety assessment is necessary. If necessary, FSIS will schedule a food safety assessment and verify whether the establishment is able to produce safe and wholesome beef products in accordance with FSIS statutory and regulatory requirements.

During the food safety assessment, FSIS EIAOs review the establishment\u2019s food safety system as a whole, including the design of the establishment\u2019s HACCP system, supporting documentation for decisions made in the hazard analysis (e.g., validation documents), the design and implementation of the establishment\u2019s sampling and testing programs, and the establishment\u2019s reaction to sampling results. Instructions to FSIS EIAOs on how to conduct public health risk evaluations and perform food safety assessments are provided in FSIS Directive 5100.4 Enforcement, Investigations and Analysis Officer", "FSIS Responses to the SRT (v2019-001) 39 (EIAO) Public Health Risk Evaluation (PHRE) Methodology and FSIS Directive 5100.1 Enforcement, Investigations, and Analysis Officer (EIAO) Comprehensive Food Safety Assessment Methodology. Lastly, if an establishment ships STEC positive product into commerce (determined through either establishment testing or official government verification testing), FSIS can take enforcement actions per 9 CFR 500. Instructions to FSIS personnel, such as FSIS OIEA compliance officers and FSIS OFO District Managers, on the methodology to use when deciding whether to implement administrative enforcement actions are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. Instructions to FSIS OIEA compliance officers on the procedures to follow when taking

enforcement actions are provided in FSIS Directive 8010.5 Case Referral and Disposition. 30. How does the CCA ensure through sampling and other verification activities that RTE meat and poultry products and all lots of pasteurized egg products are not contaminated with microbiological pathogens or their toxins, including Lm and Salmonella? FSIS considers all RTE meat, poultry products, and pasteurized egg products to be adulterated under the FMIA (21 U.S.C. 601(m)(1)), PPIA (21 U.S.C. 453(g)(1)), and EPIA (21 U.S.C. 1033(a)(1)) if contaminated with any level of Lm or Salmonella. Further, FSIS identifies RTE product as adulterated if it passes over a food contact surface that has tested positive for Lm or Salmonella. To ensure that RTE products are free of Lm and Salmonella, FSIS implements official government verification sampling and testing programs (i.e., routine, follow-up, and import sampling) and performs routine nonsampling government verification activities (e.g., HACCP, sanitation, labeling). The regulations requiring control of Lm in post-lethality exposed RTE products are contained in 9 CFR 430.4 (also known as the Listeria Rule), and state that Lm is a hazard that establishments producing post-lethality exposed RTE meat or poultry products must control through their HACCP plans, or prevent in their processing environment through the implementation of Sanitation SOP\u2019s or other prerequisite programs. (NOTE: Establishments producing RTE Siluriformes products are subject to the requirements of the Listeria rule as specified in 9 CFR 548.5.) In order to maintain the sanitary conditions necessary to meet this requirement, establishments are required to comply with the requirements of one of three Listeria alternatives listed in 9 CFR 430.4. For example, Alternative 1 uses a post-lethality treatment (PLT) and an antimicrobial agent or process (AMAP) to control Lm and requires that the PLT be included in the HACCP plan. Alternative 2b (AMAP alone) and Alternative 3 (sanitation alone) both require establishment testing of food contact surfaces in the post-lethality processing environment for Lm or an appropriate indicator organism. Establishments with processes falling in Alternatives 2b or 3 are also required to identify the size, site location, frequency of testing, and conditions under which the establishment will hold and test the product following a positive test for Listeria spp. on a food contact surface. FSIS IPP perform routine verification activities (i.e., HACCP, sanitation, and labeling) to verify that the design and execution of the establishment\u2019s programs meet the requirements of 9 CFR 430.4. For example, FSIS IPP perform sanitation verification activities at least twice per production week in RTE establishments to verify that establishments design and execute their Sanitation SOPs to prevent contamination of food contact surfaces or adulteration of RTE products with Lm and other pathogens prior to and during operations in the post-lethality environment. FSIS IPP also perform routine HACCP verification activities at least twice per production week to verify that establishments design and execute their HACCP plan effectively to control contamination of food contact surfaces or adulteration of RTE products with Lm and other pathogens. This includes verifying that establishments that use post-lethality treatments to reduce or eliminate microorganisms on the product include the post-lethality treatment in their HACCP plan (as required per 9 CFR 430.4). FSIS IPP also perform quarterly hazard analysis verification activities to verify that establishments producing RTE products are identifying and", "FSIS Responses to the SRT (v2019-001) 40 adequately addressing Lm and other pathogens in their hazard analyses. In addition, FSIS IPP perform at least one general labeling verification activity per production week to verify that product that is labeled as RTE product meets the requirements in 9 CFR 318.17, 318.23, or 381.150. Additional information on the routine verification activities

used by FSIS IPP to verify establishment compliance with 9 CFR 430.4, including instructions to FSIS IPP on how and when to document noncompliance and take enforcement actions, can be found in FSIS Directive 10,240.4 Verification Activities for the Listeria monocytogenes (Lm) Regulation and the Ready-to-Eat (RTE) Sampling Program. Instructions to FSIS IPP on how to review establishment testing data are provided in FSIS Directive 5000.2 Review of Establishment Data by Inspection Personnel. Furthermore, as part of these routine HACCP verification activities, FSIS IPP verify that establishments perform ongoing verification activities to ensure their food safety inspection system is functioning as intended and continues to support decisions made in their hazard analysis, such as conducting ongoing establishment testing for Lm (or an indicator organism) on food contact surfaces in the post-lethality processing environment (as required by certain Listeria alternatives) to demonstrate that their HACCP and sanitation systems are working effectively to eliminate or reduce Lm to a non-detectable level. FSIS IPP review establishment testing data and results at least once per production week for trend analysis. When reviewing establishment testing data, FSIS IPP verify that establishments that received positive Lm (or an indicator organism) results from their establishment testing program for food contact surfaces perform corrective actions per 9 CFR 416.15 or 9 CFR 417.3. For example, in establishments producing RTE products under Alternative 3, FSIS IPP verify that establishments perform follow-up sampling on food contact surfaces for Lm or an indicator organism in accordance with 9 CFR 430.4(b)(3)(ii)(A). FSIS considers post-lethality exposed RTE product that passed over the food contact surface that tested positive for Lm through establishment testing, or the product that tested positive for Lm through establishment testing, to be adulterated per 21 USC 601(m)(1). If the establishment fails to perform adequate corrective actions in response to positive Lm establishment test results, and the product is shipped into commerce, FSIS can take enforcement actions per (9 CFR 500). Instructions to FSIS IPP on how to review establishment testing data are provided in FSIS Directive 5000.2 Review of Establishment Data by Inspection Personnel. Instructions to FSIS IPP on how to verify adequate corrective actions in the event of positive establishment test results are provided in FSIS Directive 10,240.4 Verification Activities for the Listeria monocytogenes (Lm) Regulation and the Ready-to-Eat (RTE) Sampling Program. In addition to verifying compliance with the Lm requirements in 9 CFR 430.4 for RTE products, FSIS IPP perform HACCP verification activities to verify that establishments employ adequate lethality and stabilization procedures to meet the lethality performance standards for Salmonella in 9 CFR 318.17(a)(1) (meat) and 9 CFR 381.150(a)(1) (poultry). FSIS IPP also verify that establishments comply with the stabilization requirements (to prevent the growth of Clostridium botulinum (C. botulinum) and limit the growth of Clostridium perfringens (C. perfringens) in RTE products) in 9 CFR 318.17(a)(2) and 318.23(c)(1)(meat), and 9 CFR 381.150(a)(2)(poultry). Additionally, FSIS recommends a 5.0-log<sub>10</sub> reduction of E. coli O157:H7 in RTE fermented products containing beef. Instructions to FSIS IPP on how to verify that an establishment's lethality and stabilization procedures meet regulatory requirements, including the actions to take in the event of a heating or cooling deviation, are provided in FSIS Directive 7111.1 Verification Procedures for Lethality and Stabilization. Furthermore, if FSIS determines that an establishment produced and shipped adulterated RTE products containing pathogens that are injurious to health due to inadequate lethality or stabilization procedures (21 USC 601(m)(1) and 453(g)(1)), or that an establishment has shipped products that were

prepared, packed, or held under insanitary conditions (21 U.S.C. 601(m)(4) and 453(g)(4)), FSIS can take enforcement actions per 9 CFR 500. Instructions to FSIS personnel, such as FSIS OIEA compliance officers and FSIS OFO District Managers, on the methodology to use when deciding whether to implement administrative enforcement actions are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. Instructions to FSIS OIEA compliance officers on the procedures to follow when taking enforcement actions are provided in "FSIS Responses to the SRT (v2019-001) 41 FSIS Directive 8010.5 Case Referral and Disposition. FSIS performs government verification testing for Lm and Salmonella in both post-lethality exposed and non-post-lethality exposed RTE products. These product samples are collected and submitted by FSIS IPP under the RTE routine sampling program. Additional information on the scheduling criteria FSIS uses to assign samples under the RTE routine sampling program can be found under Updates to Random and Risk-based Scheduling Criteria for the Ready-to-Eat (RTE) Product Routine Sampling Program. In addition, FSIS performs verification testing for Lm in product, and on food contact surfaces and environmental (non-food contact) surfaces under its routine risk-based Lm (RLm) sampling program; and verification testing for Lm and Salmonella on product, food contact surfaces, and environmental surfaces, in response to positive government verification results or a documented change in an establishment's production process that may impact public health, under its Intensified Verification Testing (IVT) program. Further, when performing government verification testing for Lm and Salmonella in RTE products, FSIS considers the sampled lot to be the product produced from clean-up to clean-up (i.e., a product lot separated by complete cleaning and sanitizing), unless the establishment has another supportable lot definition. Additionally, FSIS requires establishments to hold or control RTE product tested by FSIS for Lm or Salmonella, and RTE product that has passed over food contact surfaces tested by FSIS for Lm or Salmonella, pending acceptable FSIS test results (76 FRN 19955). (NOTE: FSIS discontinued testing RTE samples for the presence of E. coli O157:H7 in dried/semi-dried, fermented sausages and cooked meat patties after an analysis showed that testing over 10,000 such products over a nine-year period yielded no E. coli O157:H7 positive samples.) Instructions to FSIS IPP on how to collect and submit official government verification samples for Lm and Salmonella in RTE products, including verifying that the establishment holds or retains control of the RTE product pending acceptable FSIS test results, can be found in FSIS Directive 10,240.4 Verification Activities for the Listeria monocytogenes (Lm) Regulation and the Ready-to-Eat (RTE) Sampling Program. Furthermore, if an official government verification test result is confirmed positive for Lm or Salmonella in RTE product, FSIS IPP verify that establishments take adequate corrective actions per 9 CFR 416.15 or 417.3. In addition, FSIS will conduct a public health risk evaluation, to assess and analyze the establishment's food safety system and determine if an immediate enforcement action or food safety assessment (including sampling under the IVT testing program) is necessary. If necessary, FSIS will schedule a food safety assessment and verify whether the establishment is able to produce safe and wholesome RTE meat or poultry products in accordance with FSIS statutory and regulatory requirements. During the food safety assessment, FSIS EIAOs review the establishment's food safety system as a whole, including the design of the establishment's HACCP system, supporting documentation for decisions made in the hazard analysis (e.g., validation documents), the design and implementation of the establishment's sampling and testing programs, and

the establishment's reaction to sampling results. Further, during food safety assessments, FSIS EIAOs conduct routine RLm sampling and IVT sampling (in response to a positive government verification results for Lm or Salmonella or a documented change in an establishment's production process that may impact public health). FSIS EIAOs also verify that establishments take adequate corrective actions in the event of a positive official government test result for Lm and Salmonella (either food contact surface or product). If an establishment does not perform adequate corrective actions in the event of a positive official government test result for Lm or Salmonella on food contact surfaces or in product, and the postlethality exposed RTE product that passed over the food contact surface that tested positive for Lm or Salmonella enters commerce, or the product that tested positive for Lm or Salmonella enters commerce, FSIS can take enforcement actions (9 CFR 500). Instructions to FSIS EIAOs on how to conduct public health risk evaluations and perform food safety assessments are provided in FSIS Directive 5100.4 Enforcement, Investigations and Analysis Officer (EIAO) Public Health Risk Evaluation (PHRE) Methodology and FSIS Directive 5100.1 Enforcement, Investigations, and Analysis Officer (EIAO) Comprehensive Food Safety Assessment Methodology. Instructions to FSIS EIAOs on how to collect and submit samples under the RLm testing program are provided under FSIS Directive 10,240.5", "FSIS Responses to the SRT (v2019-001) 42 Verification Procedures for Enforcement, Investigations and Analysis Officers (EIAOs) for the Listeria monocytogenes (Lm) Regulation and Routine Risk-Based Listeria monocytogenes (RLm) Sampling Program. Instructions to FSIS EIAOs on how to collect and submit samples under the IVT testing program are provided under FSIS Directive 10,300.1 Intensified Verification Testing (IVT) Protocol for Sampling of Product, Food Contact Surfaces and Environmental Surfaces for Listeria Monocytogenes. In egg products establishments, FSIS collects and tests dried, frozen, and liquid pasteurized egg products for Lm and Salmonella under its egg monitoring (EM) sampling program as described in FSIS Directive 10,210.1 Unified Sampling Form. In addition, egg products establishments are required to submit pasteurized egg products and all lots of dried egg products to an FSIS approved laboratory for Salmonella testing and analysis. Any product found to be Salmonella positive is required to either be reprocessed, pasteurized, and analyzed for the presence of Salmonella, or denatured (9 CFR 590.420(c), 590.422, 590.504(o)(1), and 590.580). Instructions to FSIS IPP on how to verify that establishments are complying with their Salmonella surveillance program are provided in FSIS Directive 10,230.4 Salmonella Surveillance Program for Liquid and Frozen Egg Products. Instructions to FSIS IPP on how to perform routine verification activities (e.g., sanitation, labeling) in egg products establishments can be found in FSIS Directive 5030.1 Inspection Methodology Utilizing the Public Health Information System (PHIS) for the Verification of Regulatory Compliance in Egg Products Plants. Information on the proposed number of Lm and Salmonella official government verification samples for FY17 for RTE meat and poultry products and egg products, food contact surfaces, and environmental surfaces, the actual number of samples collected and analyzed for FY17, and the proposed number of samples for FY18 can be found in the FSIS Annual Sampling Program Plan. Information on FSIS's Lm and Salmonella sampling program for imported RTE meat and poultry products and egg products can also be found in the FSIS Annual Sampling Program Plan. FSIS's validated analytical methods for isolating and identifying Lm (Chapter 8) and Salmonella (Chapter 4) in RTE meat and poultry products and egg products are contained in the MLG. Lastly, further information on

FSIS's sampling program for Lm and Salmonella in RTE meat and poultry products, including results for 2017, can be found under Testing Program for RTE Meat and Poultry on the FSIS website; and further information on FSIS's EM sampling program for egg products, including results for 2017, can be found under Testing Program for Pasteurized Egg Products on the FSIS website.

31. How does the CCA ensure that RTE shelf-stable meat and poultry products that do not rely on cooking alone to achieve lethality, such as fermented, acidified, salt-cured or dried meat and poultry products, achieve adequate lethality and shelf-stability to prevent contamination with microbiological pathogens or their toxins (e.g., Salmonella, Lm and STEC (in beef products), C. perfringens, C. botulinum, and Staphylococcus aureus (S. aureus))? FSIS maintains lethality performance standards for Salmonella in RTE products in 9 CFR 318.17(a)(1) (meat) and 9 CFR 381.150(a)(1) (poultry); and stabilization performance standards to prevent the growth of C. botulinum and limit the growth of C. perfringens in RTE products in 9 CFR 318.17(a)(2) and 318.23(c)(1)(meat), and 9 CFR 381.150(a)(2)(poultry). In RTE shelf-stable meat and poultry products, FSIS considers achieving at least a 5-log reduction in Salmonella and STEC (in beef products) to be a sufficient pathogen reduction target in protecting public health.

Further, FSIS requires all establishments to conduct a hazard analysis to identify any food safety hazards that are reasonably likely to occur during the production process (9 CFR 417.2). In establishments producing RTE shelf-stable meat and poultry products that do not rely on cooking alone to achieve lethality, such as fermented, acidified, salt-cured or dried meat and poultry products, FSIS IPP perform routine HACCP verification activities (both recordkeeping and observation) and quarterly hazard analysis verification activities to verify that establishments are effectively implementing their HACCP system to control pathogens during the lethality and stabilization processes.", "FSIS Responses to the SRT (v2019-001) 43 In particular, FSIS IPP verify during routine HACCP verification activities that establishments have included in their HACCP plan the overall performance standard or pathogen reduction target in the multiple processing steps (e.g., a 2-log reduction of Salmonella on source materials through antimicrobial intervention, 2-log reduction of Salmonella by marinating product in a low pH marinade, and 2-log reduction of Salmonella through drying achieve the pathogen reduction target of at least a 5log reduction in Salmonella in shelf-stable meat and poultry products). FSIS IPP also verify during the quarterly hazard analysis verification activity that establishments maintain adequate scientific support that the lethality steps combined achieve the performance standard or target. For stabilization, FSIS IPP verify during the quarterly hazard analysis verification activity that establishments have identified and maintain supporting documentation for the amount of growth of S. aureus they will allow during processing (e.g., during fermentation\acidification, salt-curing, or drying) and during storage under ambient conditions (e.g., up to 2-logs growth during processing and no growth during storage). In addition, FSIS IPP verify during routine HACCP verification activities that establishments continue to meet the critical operational parameters identified in their HACCP plans to prevent the growth of spore-formers during the stabilization process (e.g., a pH \u2264 4.6 before cooling or water activity (aw) <0.93 before cooling to prevent the growth of C. perfringens and C. botulinum). Instructions to FSIS IPP on how to perform HACCP verification activities in establishments that achieve lethality and stabilization by processes, such as fermentation\acidification, salt-curing, and drying, including how and when to document noncompliance and take enforcement measures, can be found in FSIS Directive 7111.1

Verification Procedures for Lethality and Stabilization. 32. How does the CCA ensure that heat-treated not ready-to-eat (NRTE) meat and poultry products are properly stabilized to prevent outgrowth of microbiological pathogens or their toxins (i.e., *C. perfringens* and *C. botulinum*), and properly labeled to ensure adequate cooking by the consumer? FSIS maintains stabilization performance standards for NRTE partially cooked and char-marked meat patties in 9 CFR 318.23(c)(1) and partially cooked poultry breakfast strips (e.g. turkey bacon) in 9 CFR 381.150(b). In establishments producing other NRTE, heat-treated, not fully-cooked products, FSIS verifies that establishments consider the food safety hazards that are reasonably likely to occur in their stabilization processes and establish steps to prevent, eliminate, or reduce those hazards to an acceptable level (9 CFR 417.2). In establishments producing heat-treated NRTE meat and poultry products, FSIS IPP perform routine HACCP verification activities (both recordkeeping and observation) and quarterly hazard analysis verification activities to verify that establishments are effectively implementing their HACCP system to control pathogens during the stabilization processes. Instructions to FSIS IPP on how to verify that establishments are preventing the outgrowth of microbiological pathogens or their toxins during the stabilization of NRTE meat and poultry products, including how to verify adequate corrective actions in the event of a cooling deviation and how and when to document noncompliance, can be found in FSIS Directive 7111.1 Verification Procedures for Lethality and Stabilization. If FSIS determines that the establishment did not take adequate corrective actions and shipped heat-treated NRTE products that were prepared, packed, or held under insanitary conditions (21 U.S.C. 601(m)(4) and 453(g)(4)), FSIS can take enforcement actions per 9 CFR 500. Furthermore, FSIS IPP perform routine labeling verification activities to verify the following: NRTE products are labeled with safe handling instructions as required per 9 CFR 317.2(l) (meat) and 9 CFR 381.125(b) (poultry); and NRTE products that are not shelf-stable are labeled with special handling statements, such as keep refrigerated or keep frozen as required per 9 CFR 317.2(k) (meat) and 381.125(b) (poultry). Instructions to FSIS IPP on how to perform labeling verification activities for NRTE meat and poultry products, including how and when to document noncompliance and take", "FSIS Responses to the SRT (v2019-001) 44 enforcement measures, are provided in FSIS Directive 7221.1 Prior Labeling Approval. 33. How does the CCA ensure that the processing of canned meat and poultry products addresses *C. botulinum* and the finished products are commercially sterile? FSIS ensures that thermally processed\commercially sterile meat and poultry products are free of microorganisms capable of growing in non-refrigerated conditions in storage and distribution (over 50\u00b0F or 10\u00b0C) by verifying that establishments employ either HACCP to control microbiological food safety hazards (9 CFR 417), or follow the regulatory \u201ccanning\u201d requirements in 9 CFR 431 to prevent microbiological contamination from occurring during the thermal process. (NOTE: FSIS recently consolidated its canning regulations for meat (9 CFR 318, Subpart G) and poultry (9 CFR 381, Subpart X) into one section in 9 CFR. These regulations are now located in 9 CFR 431 as outlined in 83 FR 25302 \u201cElimination of Trichinae Control Regulations and Consolidation of Thermally Processed, Commercially Sterile Regulations\u201d.) In establishments that choose to address the microbiological food safety hazards in the thermal process through their HACCP system, FSIS IPP perform routine HACCP verification activities to verify compliance with all 9 CFR 417 regulatory requirements. Instructions to FSIS IPP on how to verify HACCP regulatory compliance, including how and when to document noncompliance and take enforcement

measures, are provided in FSIS Directive 5000.1 Verifying an Establishment's Food Safety System. 9 CFR 431.1 provides the regulatory definitions for thermal process, a canned product, and an abnormal container. Thermal process is defined as the heat treatment necessary to achieve shelf stability as determined by the establishment's processing authority. It is quantified in terms of time and temperature, or minimum product temperature. Canned product is defined as a meat or poultry product with a water activity above 0.85 that receives a thermal process either before or after being packed in a hermetically sealed container. An abnormal container is defined as a container with any sign of swelling or product leakage or any evidence that the contents of the unopened container may be spoiled. When establishments follow the regulatory requirements in 9 CFR 431, this can be used to support that a microbiological hazard is not reasonably likely to occur (9 CFR 417.5(a)(1)). Thus, establishments are not required to address microbiological hazards in their HACCP plan (9 CFR 417.2(b)(3)). However, establishments are still required to conduct a hazard analysis per 9 CFR 417.2 to address any chemical or physical food safety hazards that could occur during their process. FSIS IPP verify that establishments continue to support their decision in the hazard analysis that microbiological contamination is not reasonably likely to occur, by performing routine verification activities to verify compliance with all FSIS canning requirements, including, but not limited to, the following: posting the process schedules in a location visible to the operator and the government inspector; maintaining a process schedule appropriate for the product and type of container being used; no unauthorized change in product formulation, equipment, or treatment that was not already incorporated in the process schedule; initial temperature was measured and recorded by the establishment; all critical factors associated with the production lot were met; required processing and production information was correctly recorded; any process deviation was handled appropriately; only normal containers were selected for incubation (if applicable), and only normal appearing containers were shipped from the establishment, as determined by an appropriate finished product inspection program; and the establishment reviewed all processing and production records no later than one working day after the actual process, to verify the completeness of the records and to determine whether all products received the process schedule. All records including the temperature/time recorder charts and critical factor control records are signed or initialed and dated by the person conducting the review. The 9 CFR 431 regulations also specify the corrective actions to be taken whenever there is a deviation", "FSIS Responses to the SRT (v2019-001) 45 from the process schedule (9 CFR 431.9). Instructions to FSIS IPP on how to verify compliance with 9 CFR 431 canning regulations, including how and when to document noncompliance and verify appropriate corrective actions, are provided in FSIS Directive 7530.2 Verification Activities in Canning Operations that Choose to Follow the Canning Regulations. Instructions to IPP on how to handle a process deviation or abnormal container of thermally processed/ commercially sterile product are provided in FSIS Directive 7530.1 Handling a Process Deviation or Abnormal Container of Thermally Processed, Commercially Sterile Canned Product. Instructions to FSIS IPP on how to examine the condition of canned product containers are provided in FSIS Directive 7520.2 Procedures for Condition of Canned Product Container Examination. Lastly, if FSIS determines that an establishment has shipped adulterated thermally processed/commercially sterile products into commerce, FSIS can take enforcement actions per 9 CFR 500. Instructions to FSIS personnel, such as FSIS OIEA compliance officers and FSIS

OFO District Managers, on the methodology to use when deciding whether to implement administrative enforcement actions are provided in FSIS Directive 5100.3 Administrative Enforcement Action Decision-Making and Methodology. Instructions to FSIS OIEA compliance officers on the procedures to follow when taking enforcement actions are provided in FSIS Directive 8010.5 Case Referral and Disposition."]}, {"file\_name": "FSIS\_GD\_2019\_0018", "title": "FSIS Guidance for a Suggested Reporting Table for the Certified Establishment List", "num": "FSIS-GD-2019-0018", "id": "b4902b84b851946a1129e9a8bfb677d1b678137bbd3eba1d18f4b41fa8ca3c78", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/media\_file/2021-03/Suggested%20Reporting%20Table%20Certified%20Establishment%20List.pdf", "type": "pdf", "n\_pages": 2, "word\_count": 1290, "text\_by\_page": ["1 FSIS Guidance for a Suggested Reporting Table for the Certified Establishment List By May 18th of each year, the Central Competent Authorities (CCAs) of countries wishing to maintain on-going equivalence and continue actively exporting meat, poultry, or egg products to the United States (U.S.) are required to provide the United States Department of Agriculture (USDA), Food Safety and Inspection Service (FSIS) an up-to-date list of all certified establishments used in the production of products eligible for export to the U.S. Therefore, if the production chain involves more than one establishment (e.g., beef is slaughtered at one establishment, further processed at a different establishment, packaged and labeled at yet another establishment, and then exported to the U.S. from a different establishment), each establishment in the production chain, including the establishment providing the raw source material and the storage facility from where the product is exported, must be listed on the certified establishment list. Furthermore, countries that are not eligible to export raw product directly to the U.S. (e.g., due to USDA Animal and Plant Health Inspection Service (APHIS) animal disease requirements), but are eligible to use their own raw source materials to produce processed products are required to certify and list the establishments providing the raw source materials. Lastly, when listing an establishment that provides raw source material, please clearly identify the establishment as a source establishment on the certified establishment list. The reporting table below may be used to assist CCAs with providing the required information to FSIS by May 18th of each year. The format of the table is optional; however, the information noted with an asterisk (\*) is required to be sent to FSIS annually. For each certified establishment, CCAs should only include products that the country is currently eligible to export to the U.S., including raw source materials for further processing. In addition, if your country is prevented from exporting certain meat, poultry, or egg products to the U.S. due to an APHIS animal disease requirement, FSIS requests that the CCA clearly identify the product categories and product groups that each certified establishment intends to export to the U.S. To view which products your country is currently eligible to export to the U.S., refer to FSIS Import Library- Eligible Countries and Products. For a list of product categories and product groups, please refer to the FSIS Product Categorization Guide. Certified establishments that are no longer eligible to export products to the U.S. must be identified as delisted on the list provided to FSIS. Furthermore, FSIS requests that CCAs inform FSIS of any establishment delisting within 90 days. CCAs can submit the required information to FSIS by either uploading it into our Public Health Information System (PHIS) under question 4 of the 2019 self-reporting tool (SRT), or by submitting it to our International"]}]

Coordination Executive at: US Department of Agriculture Food Safety and Inspection Service, Office of International Coordination, Room 3143 South Building, 1400 Independence Ave SW, Washington D.C. 20250-3700 E-mail: InternationalCoordination@usda.gov Date \u00b9\*

Eligibility Status \u00b2\* Establishment Number\* Establishment Name\* Establishment Address\* Type(s) of Operation\u00b3\* Process Category\u2074\* Species\u2075 \* Product Category Product Group MMI\DD\YYYY 1. Date \u2013 The date of an establishment\u2019s initial certification, delisting, or relisting. 2. Eligibility Status \u2013 If an establishment listed on the previous year\u2019s certified establishment list remains eligible to export products to the U.S., please leave this field blank. \u2022 New - Establishments that are newly certified as eligible to export products to the U.S. that were not previously certified as eligible to export products to the U.S. \u2022 Delisted \u2013 Establishments that were previously certified as eligible to export products to the U.S. and are no longer eligible to export products to the U.S. \u2022 Relisted \u2013 Establishments that were previously delisted and have been relisted as certified as eligible to export products to the U.S. 3. Type(s) of Operation \u2013 Slaughterhouse, Non-Slaughter Processing, Egg Processing, Cold Storage, Exporting Warehouse, or Source Establishment. \u2022 Slaughterhouse \u2013 Establishments where healthy, live animals are humanely slaughtered under sanitary conditions to produce meat or poultry products for human consumption. \u2022 In slaughter operations, FSIS requires continuous government inspection during slaughter activities to ensure that each and every livestock carcass, head, and viscera and each and every poultry carcass and viscera are inspected. \u2022 Non-Slaughter Processing - Operations include all non-slaughter activities, including but not limited to, boning, cutting, slicing, grinding, injecting, pumping, filleting, breading, adding ingredients through other mechanical means, formulating, cooking, smoking, cooling, assembling, and packaging.", "FSIS Guidance for a Suggested Reporting Table for the Certified Establishment List 2 \u2022 In processing operations (i.e., non-slaughter), FSIS requires that a government inspector be on the premises and performing inspection activities at least once per production shift during processing operations. The requirement for government inspection once per production shift during processing operations is not the same as inspection once daily; therefore, if an establishment has more than one production shift per day during which it produces product for export to the U.S., a government inspector must be present at least once during each production shift. \u2022 Egg Processing - Manufacturing of egg products, including breaking eggs, filtering, mixing, blending, pasteurizing, stabilizing, cooling, freezing, drying, or packaging egg products at certified establishments. \u2022 Cold Storage \u2013 Facility that receives and stores meat, poultry, or egg products from certified establishments and maintains products under refrigeration until export to the U.S. \u2022 Exporting Warehouse \u2013 Facility that receives and stores meat, poultry, or egg products from certified establishments until export to the U.S. Additionally, the facility where export verification and certification services for exports are provided. \u2022 Source Establishment - Slaughter establishment that provides raw source materials to certified establishments for the production of processed products intended for export to the U.S. Source establishments are not eligible to export product directly to the U.S. due to disease restrictions, regionalization, product ineligibility, or other reasons. However, source establishments must meet all U.S. requirements, be certified by the CCA, and be identified as a source establishment on the certified establishment list. 4. Process Category \u2013 1. Raw \u2013 Non Intact 4. Not Heat Treated - Shelf Stable 7. Heat

Treated - Not Fully Cooked - Not Shelf Stable 2. Raw - Intact 5. Heat Treated - Shelf Stable 8. Product with Secondary Inhibitors - Not Shelf Stable 3. Thermally Processed - Commercially Sterile 6. Fully Cooked - Not Shelf Stable 9. Eggs\Egg Products For the purposes of this document the term \u201cprocessed\u201d refers to raw meat or poultry product that has been modified through an additional processing step. Methods of processing meat and poultry products include, but are not limited to, cooking, salting, curing, aging, fermentation, and smoking. Simple mechanical processes (sometimes referred to as further processing) such as cutting, grinding, or mixing of raw meat or poultry product are not included in this definition. \u2022 Raw meat and poultry products may be produced and certified under the following FSIS Process Categories: \u2022 Raw Product - Non-Intact and \u2022 Raw Product \u2013 Intact. \u2022 Processed meat and poultry products may be produced and certified under the following FSIS Process Categories: \u2022 Thermally Processed - Commercially Sterile, \u2022 Not Heat Treated - Shelf Stable, \u2022 Heat Treated - Shelf Stable, \u2022 Fully Cooked - Not Shelf Stable, \u2022 Heat Treated - Not Fully Cooked -Not Shelf Stable, and \u2022 Products with Secondary Inhibitors - Not Shelf Stable. The term \"egg products\" refers to eggs that are removed from their shells for processing. 5. Species \u2013 F: fish of the order Siluriformes O: lamb\mutton (ovine) SQ: squab B: beef (bovine) P: pork (porcine) EM: emu V: veal D: duck OS: ostrich CH: chicken GO: goose R: rhea C: goat (caprine) GU: guinea T: turkey

NOTE: This document is updated from the 2018 version but does not contain substantive changes to the suggested reporting format. FSIS requests that all eligible countries submit their 2019 Microbiological Sampling and Testing Program Plan and 2018 Microbiological Sampling and Testing Program Results. The tables included in this guidance are intended to assist Central Competent Authorities (CCAs) in providing FSIS with the information requested in FSIS\u2019s SelfReporting Tool (SRT) question, Government Microbiological Testing Programs. FSIS is providing suggested reporting table formats for the annual data submissions of the 2019 Microbiological Sampling and Testing Program Plan and 2018 Microbiological Sampling and Testing Program Results that are due to FSIS by May 18, 2019. The use of these reporting table formats is optional; FSIS will review information submitted in other formats that incorporate the necessary information. The information that should be submitted includes: \u2022 2019 Microbiological Sampling and Testing Program Plan (Tables 1 and 2 \u2013 suggested reporting format) 1) The types of products or production classes and the types of microbiological analyses that are included in government verification sampling programs for those products or production classes 2) The method\type of sample collection 3) The test portion that is

analyzed for each type of sample that is collected 4) The microbiological methodology used to analyze the sample, including the screening method used as part of detection, if applicable 5) Planned frequency of testing for eligible establishments for each of the products or process categories \u2022 2018 Microbiological Sampling and Testing Program Results (Table 3 \u2013 suggested reporting format) 1) The actual number of samples analyzed for each product type or production class for each pathogen 2) The established criteria by which the analysis result is evaluated for compliance (e.g., number of allowed positives) 3) Regarding follow-up to unacceptable test results from government testing, submit a list of eligible establishments with unacceptable sampling results, including the number of samples analyzed, the number of unacceptable results, and the CCA\u2019s enforcement strategy in response to unacceptable results. Regarding the 2019 Microbiological Sampling and Testing Program Plan, FSIS is including the attachment, FSIS Government Microbiological Sampling and Testing Program, as a reference. This attachment includes sampling and testing frequencies for FSIS government testing programs. The 2019 Microbiological Sampling and Testing Program Plan and the 2018 Microbiological Sampling and Testing Program Results can be submitted to FSIS by either uploading it into our Public Health Information System (PHIS) under SRT question, Government Microbiological Testing Programs, or by submitting it to our International Coordination Executive at: US Department of Agriculture Food Safety and Inspection Service Office of International Coordination Room 3143, South Building 1400 Independence Ave SW Washington D.C. 20250-3700 Fax: 1-202-690-3856 E-mail: InternationalCoordination@fsis.usda.gov", "FSIS Guidance on Suggested Reporting Tables for the Government Microbiological Sampling and Testing Program NOTE: This document is updated from the 2018 version but does not contain substantive changes to the suggested reporting format. Table 1: Suggested Reporting Table for the 2019 Government Microbiological Sampling and Testing Program Annual Plan. Please include the list of products or process categories for which the CCA is currently equivalent or seeking equivalence and include a description of the method of sample collection, the test portion of the collected sample that is analyzed by the laboratory, and the analytical methods that are used by the laboratory for analysis of the samples, including reference to the screening method, if applicable. Table 2: Suggested Reporting Table for the 2019 Government Microbiological Sampling and Testing Program Annual Plan. The data reported each year should include the number of samples planned for analysis for each product type\process category and for each of the different pathogen analyses that are conducted. Additionally, the information should include the number of eligible establishments (by production volume or by volume of products exported to the US) and the total number of samples planned for those establishments in each of those categories. (The information provided in the table is for illustrative purposes only) Product Type\Process Category Pathogen Target(s) 2019 Planned Microbiological Sampling Frequency6 Very Small Est (<1,000 lbs.\day) Small Est (1,001-50,000 lbs.\day) Medium Est (50,001-250,000 lbs.\day) Large Est (>250,000 lbs.\day) # establishments exporting to US # samples\yr Raw ground beef\veal E. coli O157:H7 10 120 10 240 10 360 10 480 Salmonella 10 120 10 240 10 360 10 480 Raw beef\veal (raw beef manufacturing trimmings) E. coli O157:H7 10 120 10

240 10 360 10 480 Salmonella 10 120 10 240 10 360 10 480 Non-O157 STEC, including O26, O45, O103, O111, O121, O145 10 120 10 240 10 360 10 480 6 The volume production ranges listed are based on pounds of a specific product type or process category produced per day by a single establishment. Alternatively, the CCA may choose to use the volume of products that are exported to the US to categorize establishments eligible to export in order to determine the appropriate frequency for testing. If the frequency of sampling is based on volume of products exported to the US, the corresponding volume ranges would be: Very Small Est (<20,000 lbs./month exported to the US), Small Est (20,001-100,000 lbs./month exported to the US), Medium Est (100,001-5,000,000 lbs./month exported to the US), Large Est (>5,000,000 lbs./month exported to the US)." , "FSIS Guidance on Suggested Reporting Tables for the Government Microbiological Sampling and Testing Program NOTE: This document is updated from the 2018 version but does not contain substantive changes to the suggested reporting format. Table 3: Suggested Reporting Table for the 2018 Government Microbiological Sampling and Testing Program Annual Results. This information can be formatted similarly to the current year\u2019s proposed sampling plan (Table 2) but should include actual sampling numbers for the previous year\u2019s Government Microbiological Sampling and Testing Program. The data reported each year should include the actual number of samples analyzed for each product type\process category and for each of the different pathogen analyses that are conducted. Additionally, the information should include the number of establishments that were sampled, preferably grouped by production volume, or by volume of products exported to the US, and the total number of samples collected and analyzed at each of those establishments in the previous year. If there were positives that exceeded the criteria as outlined in the Government Microbiological Sampling and Testing Program Annual Plan (Table 1), a list of eligible establishments that failed to meet the criteria and a description of the CCA\u2019s enforcement strategy in response to unacceptable results should also be included. (The information provided in the table is for illustrative purposes only) Product Type\Process Category Pathogen Target(s) 2018 Microbiological Sampling Results7 Very Small Est (<1,000 lbs./day) Small Est (1,001-50,000 lbs./day) Medium Est (50,001-250,000 lbs./day) Large Est (>250,000 lbs./day) # establishments exporting to US # samples\yr. # establishments exporting to US # samples\yr. # establishments exporting to US # samples\yr # establishments exporting to US # samples\yr Raw ground beef\veal E. coli O157:H7 9 105 4 96 10 360 7 335 Salmonella 9 105 4 96 10 360 7 335 Raw beef\veal (raw beef manufacturing trimmings) E. coli O157:H7 10 120 10 240 5 180 10 480 Salmonella 10 120 10 240 5 180 10 480 Non-O157 STEC, including O26, O45, O103, O111, O121, O145 10 120 10 240 5 180 10 480 7 The volume production ranges listed are based on pounds of a specific product type or process category produced per day by a single establishment. Alternatively, the CCA may choose to use the volume of products that are exported to the US to categorize establishments eligible to export in order to determine the appropriate frequency for testing. If the frequency of sampling is based on volume of products exported to the US, the corresponding volume ranges would be: Very Small Est (<20,000 lbs./month exported to the US), Small Est (20,001-100,000 lbs./month exported to the US), Medium Est (100,001-5,000,000 lbs./month exported to the US), Large Est (>5,000,000 lbs./month exported to the US)." ]}, {"file\_name": "FSIS\_GD\_2019\_0020", "title": "Modernization of Swine Slaughter Inspection Webinar", "num": "FSIS-GD-2019-

Preface This is a revised version of the FSIS Guideline for Small and Very Small Plants that Produce Ready-to-Eat (RTE) Egg Products. It has been updated in response to comments received on the previous version and renamed. In addition, the guideline now includes updates for hazards related to Listeria monocytogenes (Lm) and residues, updates concerning amendments to the regulations, former regulatory parameters for defrosting, and changes to improve its readability. This guideline represents FSIS's current thinking on these topics and should be considered usable when applicable provisions in the egg products rule becomes effective. The information in this guideline is provided to assist egg products plants in meeting the regulatory requirements. The contents of this document do not have the force and effect of law and are not meant to bind the public in any way. This document is intended only to provide clarity to industry regarding existing requirements under the regulations. Under the regulations, plants may choose to implement different procedures than those outlined in this guideline, but they would need to validate and support how those procedures are effective. This guideline is focused on small and very small plants in support of the Small Business Administration's initiative to provide small businesses with compliance assistance under the Small Business Regulatory Enforcement Fairness Act (SBREFA). However, all egg products plants may apply the recommendations in this guideline. It is important that small and very small plants have access to a full range of scientific and technical support, and the assistance needed to establish safe and effective HACCP systems. Although large plants can benefit from the information, focusing the guideline on the needs of small and very small plants provides them with assistance that may be otherwise unavailable to them. Under the final rule, (Egg Products Inspection Regulations) egg products plants will be required to meet HACCP and sanitation requirements consistent with meat and poultry product regulations. This rule removes the prescriptive time and temperature parameters for egg products pasteurization, heat treatment, freezing, and cooling procedures. Instead, FSIS requires that plants support and validate procedures for lethality treatments, cooling, and freezing in its HACCP system and develop written Sanitation Standard Operating Procedures (Sanitation SOPs). In addition, egg products are required to be edible without additional preparation to achieve food safety and

are, therefore, considered ready-to-eat (RTE). Purpose of this Guideline This guideline contains information to assist plants producing egg products that undergo pasteurization, heat treatment, cooling, and freezing in complying with the new regulatory requirements in the final rule. Under 9 Code of Federal Regulations (CFR) 591.1(a), all egg products plants have to comply with the requirements contained in 9 CFR 416, Sanitation (one year after the final rule issues), 9 CFR 417, "5 Hazards Analysis and Critical Control Point Systems (HACCP) (two years after the final rule issues), and 9 CFR 500, Rules of Practice (60 days after the final rule issues). This guideline includes information on: \u2022 Regulatory requirements associated with the safe production of egg products; \u2022 HACCP requirements; \u2022 Options to achieve lethality and/or safe cooling and freezing; and \u2022 Recommendations for meeting the sampling requirements for detection of *Salmonella* spp. in egg products. Plants can always seek guidance from State university extension service specialists and HACCP Coordinators on developing programs and plans not provided in this guideline to comply with new regulatory requirements. Plants that follow the recommendations in this guideline are likely to meet the regulatory requirements. Changes from the Previous Version This guideline, dated September 9, 2020, is final. FSIS will update this guideline as necessary should new information become available. FSIS made the following change to this guideline to reflect the comments received on the previous version during the comment period for the proposed rule and to include additional scientific information: \u2022 Revised the section Pasteurization of Liquid Egg Whites (9 CFR 590.570) to state why the former regulatory time and temperature requirements for pasteurization of liquid egg whites was not included in Table 1 and to explain under what circumstances these combinations could be used; \u2022 Added Lm as a potential hazard in egg products, such as 10% salted egg products, and FSIS time and temperature pasteurization recommendations to destroy Lm; \u2022 Added the section Defrosting Operations (9 CFR 590.539) for frozen egg products that need to be defrosted or tempered; \u2022 Included egg substitutes and freeze-dried egg products; \u2022 Added acceptable culture testing methods for *Salmonella*; \u2022 Reorganized the Food Safety Systems and the HACCP Framework, Microbiological Testing Method, and New Technologies sections to improve clarity and make it more streamlined.", "6 Questions Regarding Topics in this Guideline If the desired information cannot be found within the guideline, FSIS recommends that users search the publicly posted Questions & Answers (Q&As) in the askFSIS database or submit questions through askFSIS. Documenting these questions helps FSIS improve and refine present and future versions of the guidance and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter Egg Products Guideline. Question Field: Enter question with as much detail as possible. Product Field: Select General Inspection Policy from the drop-down menu. Category Field: Select Sampling from the drop-down menu. Policy Arena: Select Domestic (U.S.) Only from the drop-down menu. When all fields are complete, press Continue.", "7 FSIS Food Safety Guideline for Egg Products Background Bacteria and viruses are common causes of foodborne illness and may be present in the environment, in live animals and on raw food. Eggs have been identified as important reservoirs for pathogens. Pathogens can be transferred to eggs during formation inside the hen; laying; and egg breaking, handling, and other processing steps. Previous FSIS regulations included prescriptive requirements for egg products plants to address contamination and did not allow flexibility for egg products plants to innovate. Under this final

rule, FSIS has adopted HACCP as the organizing structure for its egg products food safety program, consistent with current requirements in the meat and poultry products inspection regulations. Egg Products Final Rule: Amendments to the Regulations In the final rule, FSIS amended the egg products inspection regulations to require all federallyinspected egg products plants to develop and implement HACCP systems, Sanitation SOPs, and Sanitation Performance Standards (SPS) to design and support the food safety system (9 CFR 416 and 9 CFR 417). Implementation of HACCP, Sanitation SOPs, and SPS provides greater flexibility and incentives for innovation. This final rule also aligns egg products regulations with the meat and poultry products regulations. The amendments include the following (this guideline addresses the items bolded below): \u2022 Eliminate the current regulations that are inconsistent with HACCP, Sanitation SOPs, and SPS requirements; \u2022 Specify that egg products are required to be edible without additional preparation to achieve food safety; \u2022 Assert FSIS jurisdiction over egg substitutes and freeze-dried egg products; \u2022 Allow for the use of irradiated shell eggs in the production of egg products, provided the egg product subsequently undergoes pasteurization or another lethality treatment; \u2022 Provide for generic approval as part of the prior label approval system for egg products under 9 CFR 412.2; \u2022 Make changes to labeling requirements for shell eggs that are consistent with the Food and Drug Administration (FDA) regulations; ", "8 \u2022 Require special handling instructions on egg products that require special handling to maintain their wholesome condition; \u2022 Eliminate the requirements for prior approval by FSIS of egg products plant drawings, specifications, and equipment; \u2022 Incorporate egg products plants under 9 CFR 500, Rules of Practice that the Agency follows when initiating administrative enforcement actions; \u2022 Change the Agency\u2019s interpretation of the requirement for continuous inspection. The information contained within this guideline is applicable to egg products, including egg substitutes and freezedried egg products. Egg substitutes are low-cholesterol egg products. They are characterized as egg whites with nonegg yolk replacers such as vegetable oil, nonfat dry milk, soy protein, gums, food coloring, artificial flavors, and vitamins and minerals (for nutritional fortification). Freeze-dried egg products consist of an egg product that is flash frozen and placed in a vacuum chamber to remove ice particles. Known Pathogens of Concern in Egg Products While egg products can be contaminated by several pathogens, the two most common pathogens are *Salmonella* and Lm. *SALMONELLA* *Salmonella* spp. are bacterial pathogens that cause foodborne illnesses. The most common symptoms of salmonellosis are diarrhea, abdominal cramps, and fever within 12 to 72 hours after eating the contaminated food. The illness usually lasts 4 to 7 days. Salmonellosis may result in *Salmonella*-induced chronic conditions such as aseptic reactive arthritis and Reiter\u2019s syndrome (a combination of urethritis, conjunctivitis, and arthritis). Older adults, infants, and persons with weakened immune systems are more likely to develop a severe illness. The Centers for Disease Control and Prevention (CDC) reported that nontyphoidal *Salmonella* spp. are one of the leading causes of foodborne illness, with an estimated 1 million illnesses, 19,300 hospitalizations, and 380 deaths annually in the United States (Scallan, et.al., 2011). *Salmonella* spp. contamination in the final egg products can be due to underprocessing by not meeting the time and temperature parameters to achieve full lethality. Contamination can also occur Egg substitutes Egg whites with added color, mineral, or vitamin, and sold as a low-cholesterol alternative to whole egg products. Freeze-dried egg products Egg product that is flash frozen

and placed in a vacuum chamber. Egg products Broken shell eggs that are processed into liquid, frozen, or dried egg white, egg yolk, or whole egg products. Full definition may be found in 9 CFR 590.5.,"9 in the post-processing environment through contact with contaminated food contact surfaces, improper handling, addition of ingredients, and insect or animal vectors. If plants do not address pathogen reduction in their HACCP systems or do not have a process that is validated to achieve the necessary level of pathogen reduction, adulterated products may be released into commerce. Egg products found positive for *Salmonella* spp. or other pathogens are adulterated. FSIS requires plants to maintain control of products until test results (either plant testing or FSIS testing) confirm the product does not contain pathogens, such as *Salmonella* spp. (9 CFR 590.504(e)). *LISTERIA MONOCYTOGENES* (Lm) Lm is a bacterium that is found in moist environments, soil, and decaying vegetation and can persist along the food continuum. Listeriosis is a serious infection usually caused by eating food contaminated with Lm. The CDC estimates that infection with Lm causes about 1,600 illnesses, 1,500 hospitalizations, and 260 deaths in the United States each year. Listeriosis is rare, but its fatality rate is very high (about 20 percent, compared with 0.5 percent for *Salmonella* or *Escherichia coli* (*E. coli*)). It primarily affects older adults, pregnant women, newborns, and people with weakened immune systems (Scallan, et.al., 2011). Transfer of Lm from the environment or employees is a hazard of concern in RTE foods, including egg products. Lm can survive and grow at cool temperatures (as low as just above freezing). Because of Lm growth and survival characteristics, Lm is usually persistent in the environment and is commonly referred to as a harborage organism (i.e., it can form biofilms, which is a community of organisms firmly attached to a surface, that allow Lm to grow to high numbers in the environment and protect it from sanitizers). Lm can cross-contaminate food contact surfaces and foods. Improper sanitation, improper equipment maintenance, product handling, and employee practices post-lethality can lead to the transfer of Lm to egg products, causing them to become adulterated. Egg products contaminated with Lm are considered adulterated. FSIS requires plants to maintain control of products until test results confirm the product does not contain pathogens, such as Lm (9 CFR 590.504(e)). While Lm is a hazard of concern in egg products, FSIS recommends that plants continue to use *Salmonella* as an indicator of effective pasteurization in egg products because the thermal destruction of *Salmonella* in cooked products would indicate the destruction of most other pathogens (64 FR 733). Refer to the section Liquid Egg Yolks for reprocessing recommendations of egg products that test positive for Lm. Food Safety Systems and the HACCP Framework The statutory provisions require that egg products are pasteurized and not adulterated before shipping into commerce (21 U.S.C. 1036(a)). Because egg products undergo a lethality step to destroy pathogens of concern in the finished product, they can be safely consumed \u201cas is,\u201d Key Point Plants are required to process egg products to be edible without additional preparation to achieve food safety.,"10 meaning without any additional cooking or food safety interventions. Consistent with HACCP, under the final rule, the former 9 CFR 590.570 regulation was replaced by a new regulation specifying that egg products must be produced to be edible without additional preparation to achieve food safety and may receive additional preparation for palatability or aesthetic, epicurean, gastronomic, or culinary purposes. Hazards such as *Salmonella* and Lm can be prevented, eliminated, or reduced through developing a food safety system. FSIS uses the HACCP framework as its food safety system. HACCP has multiple components that together form the

HACCP system. HACCP Requirements The HACCP system is defined as the food safety system in operation, including the HACCP plan. The HACCP plan includes the hazard analysis, supporting documentation, and all HACCP records. The first step in developing a HACCP plan is to conduct a hazard analysis (9 CFR 417.2(a)). The hazard analysis must include all biological, physical, and chemical food safety hazards that can occur before entry into the plant and throughout the processing and storage. The plant would then identify the points in each of its processes at which control is necessary to prevent, eliminate, or reduce each hazard (9 CFR 417.2(c)(2)). Plants implement measures to address those hazards identified in the hazard analysis into their HACCP system, such as at the lethality treatment, cooling, and freezing process steps. For each hazard identified in the hazard analysis, the plant determines if the hazard is reasonably likely to occur (RTLO) or not reasonably likely to occur (NRLTO). For any RLTO hazard, plants are required to develop a critical control point (CCP) in their HACCP plan. Plants may also determine that a prerequisite program effectively prevents the occurrence of certain food safety hazards, so they are NRLTO, for which a CCP is not required. Prerequisite programs to HACCP may include Sanitation SOPs (9 CFR 416.11-17), as well as other prerequisite programs, such as purchase specifications. Prerequisite programs to prevent hazards should be designed and monitored to ensure they are working as intended. Written validated HACCP plans (9 CFR 417.2(b)) may include, but are not limited to, items in the list below in order to meet the 9 CFR 417 regulatory requirements: \u2022 Identification of hazards RLTO in the production process, such as *Salmonella* spp. and Lm; \u2022 Identification and description of the CCP for each identified hazard in the HACCP plan; \u2022 Specification of the critical limit that must be met at each CCP, and, if appropriate, a target limit, such as identifying time and temperature parameters for the lethality, cooling, and Definition The HACCP system is defined as the food safety system in operation, including the HACCP plan, to prevent, eliminate, or reduce food safety hazards. The HACCP plan includes the hazard analysis, supporting documentation, including prerequisite programs and scientific documentation used to support decisions, and all HACCP records.", "11 freezing procedures; \u2022 Description of the monitoring procedure, frequency, and monitoring device to be used, such as a calibrated thermometer to monitor the temperature at lethality and cooling process steps; \u2022 Description of the corrective action to be taken if the critical limit has not been met; \u2022 Description of the records that would be generated and maintained at each CCP; and \u2022 Description of the verification activities (e.g., direct observation, records review, calibration) and the frequency at which they are to be conducted along with support for these procedures and frequencies. In addition to developing a hazard analysis and HACCP plan, processors are required to develop and maintain written Sanitation SOPs to minimize the risk of direct product contamination and adulteration (9 CFR 416.11-17). The regulations require that the plant\u2019s Sanitation SOPs specify the cleaning and sanitizing procedures for all equipment and facilities involved in the production of every egg product. As part of the Sanitation SOPs, a plant employee is required to record results of sanitation checks at the frequencies stated in the Sanitation SOPs. All the records generated from monitoring CCPs, Sanitation SOPs, and other prerequisite programs become part of the HACCP system records. When conducting a pre-shipment review, the HACCP records must be reviewed and signed by a plant employee. When practicable, the review should be conducted by an employee other than the one who produced the record before the product is distributed in commerce, and preferably by someone trained in HACCP or the responsible plant official (9

CFR 417.5(c)). Lastly, HACCP records must be retained in accordance with 9 CFR 417.5(e), for at least 1 year for refrigerated products and 2 years for frozen, preserved, or shelf-stable products. HACCP Plan to Control Hazards Pasteurized egg products must be free of detectable pathogens (*Salmonella* and *Lm*) and have no violative levels of residues (pesticides, heavy metals, persistent organic pollutants) or detectable toxins or levels of toxin-producing organisms that would be a public health concern. Egg products plants produce safe product by controlling, eliminating, and reducing microbiological, physical, and chemical hazards, where identified, throughout their HACCP system. During completion of the hazard analysis, plants are required to consider and account for hazards that could occur at the farm (*Salmonella*, residues), during transportation to the plant (checking seals on trucks, performing organoleptic examinations on incoming products), and during processing at the plant (lethality, cooling, and freezing procedures, storage conditions). Plants need to verify on an ongoing basis that they are addressing the hazards identified in the hazard analysis and that the HACCP plan is functioning to ensure food safety (9 CFR 417.4(a)). Consistent with the former regulations, the amended regulations require plant-performed microbiological sampling and testing to", "12 verify the absence of *Salmonella* spp. in the finished product. Plants are required to maintain control of the egg products until the testing results are received (9 CFR 590.504(e)). Egg products may be moved from a plant before the plant receives laboratory results only if the plant retains control of the product. In the hazard analysis, the plant determines if a hazard is RLTO (addressed through a CCP) or NRLTO (typically addressed through Sanitation SOPs or other prerequisite programs). Process deviations may occur despite the best efforts of a plant to maintain process control. Heating and cooling deviations occur when the plant fails to meet its heating (i.e., pasteurization, heat treatment) or cooling process schedule. Failure to meet the time and temperature combination is a common cause of heating deviations and can result in underprocessing. Common causes for cooling deviations include inadequate chilling due to large volumes, improper agitation of the product, power failures, or refrigeration equipment breakdowns. When processing deviations occur, a plant is required to take corrective action to bring the process back in control (9 CFR 417.3). \u2022 When the identified hazards are addressed through CCPs, plants are required to determine the cause of all critical limit deviations (9 CFR 417.3(a)(1)), regain control of the CCP (9 CFR 417.3(a)(2)), and ensure measures are established to prevent recurrence (9 CFR 417.3(a)(3)). Recurring deviations constitute an unacceptable risk within the HACCP system. In addition, the plant would be required to initiate measures to ensure that no product potentially injurious to health or otherwise adulterated because of the deviation enters commerce (9 CFR 417.3(a)(4)). \u2022 When the identified hazards are addressed through a prerequisite program, plants are required to reassess their HACCP plan to determine whether the newly identified deviation (i.e., unforeseen hazard) should be incorporated into the HACCP plan (9 CFR 417.3(b)(4)). In addition, the plant may not be able to continue to support the decisions in its hazard analysis that the identified hazard is NRLTO if it has continual or repetitive deviations from its prerequisite program (9 CFR 417.5(a)(1)). If a plant fails to support decisions made in the hazard analysis or demonstrates ongoing or repetitive CCP or prerequisite program deviations, there could be an imminent food safety concern that may have an impact on public health. Producing product with potential food safety concerns can result in a regulatory control action or an enforcement action by FSIS, according to the Rules of Practice (9 CFR 500). Validation,

Verification, Reassessment Validation is the process of demonstrating that the HACCP system as designed can adequately control potential hazards to produce a safe, unadulterated product. Validation is a key step to determine if a HACCP system is effective (9 CFR 417.4(a)(1)). Key Point FSIS recommends that egg product plants use the Compliance Guideline HACCP Systems Validation document to ensure that the HACCP systems are properly validated.", "13 Validation ensures that the HACCP system is designed and functioning appropriately. Validation has two elements as described in the Compliance Guideline HACCP Systems Validation. Element 1 involves supporting the decisions made in the hazard analysis (hazards as RLTO or NRLTO) and in the HACCP plan (critical operating parameters, such as time and temperature). Examples of support are provided in the section Scientific Support Availability for Lethality Requirements in Egg Products. Plants can meet the new requirements by implementing the former regulatory time and temperature parameters in 9 CFR 590.530, 9 CFR 590.536, 9 CFR 590.539, 9 CFR 590.570, and 9 CFR 590.575 or any of the other time and temperature parameters included in this guideline. FSIS considers these parameters to be safe harbors. Safe harbors are recognized procedures that can be employed without any further validation studies. Plants will not have to gather additional scientific support for their process if they choose to use these safe harbors. Plants that choose to use the former regulations must incorporate these procedures into their HACCP system (i.e., HACCP plan, prerequisite programs, Sanitation SOPs). Element 2 involves collecting 90 calendar days of in-plant data to demonstrate that the system is capable of meeting the critical operating parameters. The in-plant validation may include in-plant observations, measurements, microbiological test results, or other information demonstrating that the control measures (CCPs and prerequisite programs), as written into a HACCP system, can be executed within a particular plant to achieve the process\u2019s intended result. Plants using existing HACCP systems developed before the issuance of this document that do not have the documents from its initial validation on file would need to gather the necessary data. Plants using safe harbors to satisfy Element 1 are still required to meet Element 2 of the validation process. Once the HACCP system is validated, the plant will need to perform on-going verification and continue to monitor those operating parameters, review records generated by the HACCP system, and maintain documentation verifying that they are following these procedures (9 CFR 417.4(a)(2)). At least annually, and anytime a process is changed, the plant must reassess their HACCP system to ensure the decisions made in the hazard analysis and HACCP plan are still valid (9 CFR 417.4(a)(3)).

Scientific Support Available for Lethality Requirements for Egg Products There are generally six types of information that can be used to demonstrate compliance with the new scientific support regulatory requirements in the final rule on Egg Products Inspection Regulations: (1) published processing guidelines, (2) challenge studies, (3) peer-reviewed scientific or technical data or information, (4) pathogen modeling programs, (5) expert advice from processing authorities, and (6) former egg products regulations. Finished product sampling results alone cannot be used to validate lethality procedures because they do not provide information on the incoming pathogen load and, consequently, the level of pathogen reduction achieved. FSIS recommends that plants refer to the guidance provided in the FSIS Compliance Guideline HACCP Systems Validation to ensure that their HACCP systems are properly validated.", "14 (1) Published Processing Guidance This guideline, as well as other guidance available on FSIS\u2019s Guidance Website, are examples of Published Processing Guidance. This Egg Products Guideline contains safe harbors from

former egg products regulations, options from approved New Technology waivers, and the mathematical time and temperature combinations for pasteurization. Figure 1 illustrates the options that plants may use to comply with the new regulatory requirements in the final rule. Appendix II, New Technology Pasteurization and Freezing Time and Temperature Tables, provides tables of validated pasteurization and freezing time and temperature parameters from historical FSIS New Technology waivers and No Objection Letters (NOLs). These tables can be used as resources to meet the proposed regulations. Appendix III, Pasteurization Time and Temperature Tables, provides tables of pasteurization time and temperature combinations that are calculated to achieve the lethality performance standard for specific egg products based on data and models that are presently available to FSIS. FSIS considers these to be scientifically validated processes and safe harbors to meet regulatory requirements. Figure 1. Overview of Options Available to Meet the New Regulatory Requirements Options available to assist plants in meeting the Egg Product Regulations for: 9 CFR 590.570 for pasteurization; 9 CFR 590.530 for cooling; 9 CFR 590.536 for freezing; and 9 CFR 590.539 for defrosting Develop your own alternative time and temperature parameters for pasteurization, heat-treatment, cooling and\or freezing. Refer to HACCP Systems Validation Compliance Guidelineto ensure proper HACCP system validation. Use the Pasteurization Time and Temperatures Tables in Appendix III. Refer to Tables III.A-III.Cto determine which time and temperature combinations are suitable for your egg operation. Refer to Table III.C for Liquid Egg Yolk Products. Refer to Table III.B for Liquid Whole Egg Products. Refer to Table III.A for Liquid Egg Whites products. Use the New Technology Pasteurization and Freezing Time and Temperature Tables in Appendix II. Refer to Tables II.A -II.Dfor new technology waivers for pasteurization time and temperatures combinations for liquid egg products Refer to Table II.E for freezing temperature parameters. Use the safe harbor former prescriptive regulationsfor pasteurization, heat treatment, cooling, freezing, and defrosting to meet the new requirements. Refer to Table 1for pasteurization time and temperature parameters. Refer to Table 2for cooling parameters. Refer to Table 3 for defrosting parameters.", "15 (2) Challenge Studies One of the most definitive validation tools available is the inoculated pack or challenge study of the time and temperature used by the plant for egg products pasteurization. Challenge studies involve inoculating the product with a known amount of a pathogen and calculating the level of reduction or elimination that is achieved. Since challenge studies introduce hazards to the product, they should be conducted in a testing laboratory and not in the processing plant environment. Such studies should be undertaken by individuals who have a thorough knowledge of laboratory methods used in lethality research for *Salmonella* spp. in liquid or dried egg products. The challenge study design, including a description of the process and all critical operating parameters affecting the reduction or elimination, and the achieved level of pathogen reduction or elimination should be documented and maintained as part of the HACCP system. Challenge studies should be based on a sound statistical design that ensures confidence in the data and employs positive and negative controls. The statistical design should include the number of samples collected at each time interval and the number of study replicates needed to ensure the validity of the study. Quantitative methods such as power analysis may be used to assess the statistical quality of a study. For more information on conducting challenge studies, please review the article published by the National Advisory Committee on Microbiological Criteria for Foods in the Journal of Food Protection in 2010. (3) Peer-Reviewed Journal Articles Published studies, such

as peer-reviewed research studies on the pasteurization of egg products, can serve as initial validation of pasteurization time and temperature parameters. Published studies should include the time and temperature requirements to achieve a specific log reduction and type of product and formulation (e.g., whole egg; whole egg with citric acid). Additional parameters could include viscosity and pH of the egg product used. To be used as part of initial validation, the study selected should describe products and processes similar to those used by the plant. The plant should not use published studies whose study parameters do not represent the plant's process and products. For example, a study on the pasteurization time and temperature for liquid egg whites is not adequate supporting documentation for the pasteurization of whole eggs. (4) Pathogen Modeling Programs FSIS is not presently aware of any publicly available computerized software available on lethality models for the inactivation of *Salmonella* spp. in liquid or dried egg products. However, such models might be developed without FSIS awareness and could be used for demonstrating compliance if the model is applicable and validated for the plant's product. Individual plants can develop their own computer models using data from published literature, provided that the assumptions used for developing the models are scientifically sound. Predictive food microbiology uses models (i.e., mathematical equations) to describe the growth, survival, or inactivation of microbes in food systems. Listed below are peer-reviewed studies using various mathematical equations to determine inactivation of heat-resistant *Salmonella* spp. strains.", "16 \u2022 Jordan, S.S., Gurtler, J.B., Marks, H.M., Jones, D.R. and Shaw, W.K. 2011. A mathematical model of inactivation kinetics for a four-strain composite of *Salmonella Enteritidis* and *Oranienburg* in commercial liquid egg yolk. *Food Microbiology*. 28:67-75. \u2022 Gurtler, J.B., Marks, H.M., Bailey, R.B, Juneja, V. and Jones, D.R. 2013. Kinetics Model Comparison for the inactivation of *Salmonella Enteritidis* and *Oranienburg* in 10% salted liquid whole egg. *Foodborne Pathogens and Disease*. 10:492-499. \u2022 Gurtler, J.B., Marks, H.M., Jones, D.R, Bailey, R.B, and Bauer, N.E. 2011. Modeling the thermal inactivation kinetics of heat-resistant *Salmonella Enteritidis* and *Oranienburg* in 10 percent salted liquid egg yolk. *Journal of Food Protection*. 74:882-892. \u2022 Gurtler, J. B., V. K. Juneja, D. R. Jones, and A. Purohit. 2019. Thermal inactivation kinetics of three heat-resistant *Salmonella* strains in whole liquid egg. *Journal of Food Protection*. 82(9):1465-1471. (5) Expert Advice from Processing Authority Expert advice from processing authorities may be used as scientific or technical support. Such expert advice should include reference to established scientific principles as well as reference to peer-reviewed scientific data. Expert advice from processing authorities should not rely on expert opinion alone. The scientific principles and data should relate to the plant's product and process as well as the hazard identified in the hazard analysis. One example of how expert advice may be used is a processing authority's justification for why a different limit of a critical operational parameter from the one studied in the scientific support should not impact the effectiveness of an intervention. As part of the justification, in addition to their own expert opinion, the processing authority should cite one or more peer-reviewed scientific data sets or documents that provide a science-based rationale for why the different limit of the critical operational parameter should be at least equally as effective from the one in the scientific support. (6) Former Egg Products Regulations The former regulations for pasteurization, heat treatment of dried egg whites, cooling, freezing, and defrosting operations could be used by a plant to meet new regulatory requirements. The former regulations are recognized as safe

harbors and are considered validated processes. Pasteurization Operations (9 CFR 590.570) Table 1 provides the former pasteurization requirements for liquid egg products. It should be noted that the time and temperature parameter for the pasteurization of liquid egg whites under the former regulations are not included here as it does not achieve the same level of lethality as for other liquid egg products and can only be used under certain conditions. In general, FSIS considers a 5-log10 reduction of Salmonella to be safe in products that are edible without additional preparation to achieve food safety, including egg products. This will eliminate up to 100,000 Colony Forming Units", "17 per gram (CFU/g) pathogenic organisms before the number of bacteria overwhelms the lethality treatment. The conditions under which liquid egg whites may be processed using the former regulatory time and temperature pasteurization combination are described in the \u201cPasteurization of Liquid Egg Whites\u201d section. Table 1. Former Pasteurization Requirements for Liquid Egg Products That Could Be Used as Safe Harbors Liquid Egg Products Minimum Temperature Requirements (\u00b0F) Minimum Holding Time Requirements (Minutes) Whole egg 140 3.5 Whole egg blends (less than 2% added nonegg ingredients) 142 140 3.5 6.2 Fortified whole egg and blends (24\u201338% egg solids, 2\u201312 percent added nonegg ingredients) 144 142 3.5 6.2 Salt whole egg (with 2% or more salt added) 146 144 3.5 6.2 Sugar whole egg (2\u201312% sugar added) 142 140 3.5 6.2 Plain yolk 142 140 3.5 6.2 Sugar yolk (2% or more sugar added) 146 144 3.5 6.2 Salt yolk (2\u201312% salt added) 146 144 3.5 6.2 Pasteurization of Liquid Egg Whites (9 CFR 590.570) Based on the scientific literature, the former regulatory pasteurization time and temperature for liquid egg whites (134\u00b0F for 3.5 minutes) did not achieve a 5-log10 reduction (International Egg Pasteurization Manual, USDA FSIS 1998 Risk Assessment) of Salmonella. This time and temperature combination may be used as a safe harbor if the eggs did not originate from a farm that is positive for Salmonella Enteritidis. The time and temperature requirements of the former pasteurization regulations were based on a pH of about 9 for egg whites, as described in the USDA FSIS 1998 Risk Assessment. At the time the regulations were written, it would take eggs 3 to 5 days to arrive at the processing plant. During this time, the pH of the albumen would rise from about 7.8 to 9.4. However, current practice allows for the eggs to arrive at the processing plant much sooner, when the pH is closer to 7.8. The pH of albumen, or the egg white, has a significant effect on the reduction of Salmonella Enteritidis when liquid egg white is pasteurized. Salmonella Enteritidis is more sensitive to heat at higher pH levels, thus making egg pasteurization more effective. Egg whites have natural antimicrobial properties that limit Salmonella growth. These properties include lysozyme, ovotransferrin, vitamin chelating proteins, and proteinase inhibitors (Baron et. al., 2016). With these inherent properties, it is possible that egg whites may not require a process that achieves a 5-log10 reduction of Salmonella under certain conditions (refrigerated within 36 hours of lay; not originating from a farm that has Salmonella Enteritidis-positive eggs). These antimicrobial properties would limit the growth of Salmonella cells present in the egg white, thus allowing for", "18 greater effectiveness of the former pasteurization time and temperature combination before the lethality treatment is overwhelmed. Available studies examined Salmonella in eggs from chickens infected with Salmonella. Humphrey et. al., (1989, 1991) enumerated Salmonella from the egg, but also looked at Salmonella growth when inoculated into different parts of the egg (albumen versus yolk). Garibaldi et. al., (1969) enumerated Salmonella from whole egg and from the albumen while Gast and Beard (1992) enumerated the Salmonella from the whole

egg. Their studies demonstrated that most eggs had less than 1-log10 of Salmonella per egg while a few eggs had 2.1-log10 of Salmonella. Humphrey et. al., (1991) determined that Salmonella inoculated into the outer edge of the albumen was less likely to grow than when inoculated next to the yolk membrane, fresh eggs were less likely to support Salmonella growth regardless of its position in the albumen, and that Salmonella positive eggs contained less than 1.3log10 of Salmonella when stored at room temperature for less than three weeks. Gast and Beard (1992) studied the effect of storage temperature on frequency of isolation and concentration of Salmonella in eggs from experimentally infected hens and determined that eggs stored at 45\u00b0F for 7 days had 0.75-log10 of Salmonella. Since that time, the industry has continued to lower Salmonella levels in egg products. FSIS performed a Salmonella baseline survey from 2012 to 2013. Results of that baseline indicate that raw liquid whole egg samples had -0.60-log10 to -0.31-log10 (95% confidence interval) Salmonella, meaning that there was 1 Salmonella organism per 2 to 4 mL. Raw liquid egg whites had -0.92-log10 to -0.24-log10 Salmonella, meaning that there was 1 Salmonella organism per 2 to 8 mL. In addition, FSIS sampling indicated that pasteurized egg whites had a Salmonella prevalence of 0.61% from 1995 to 1999. That prevalence decreased to 0.19% from 2013 to 2018. However, the FDA Final Rule: Prevention of Salmonella Enteritidis in Shell Eggs During Production, Storage, and Transportation (74 FR 33030, July 9, 2009) requires all eggs diverted from a farm that has Salmonella Enteritidis be treated using a technology or process that achieves a 5-log10 destruction of Salmonella Enteritidis. Since the former regulatory pasteurization time and temperature for liquid egg whites does not achieve a 5-log10 reduction, it was not included in Table 1. Considering this, egg products plants could use the former regulatory pasteurization time and temperature of 134\u00b0F for 3.5 minutes as a safe harbor, provided that the eggs are not diverted from a farm that has Salmonella Enteritidis. If plants are using the former pasteurization time and temperature combination and receive multiple positive Salmonella results, then they will be required to reassess their hazard analysis and make appropriate corrective actions. Plants pasteurizing liquid egg whites that require a 5-log10 reduction of Salmonella may refer to the section Liquid Egg Whites for acceptable time and temperature combinations. Heat Treatment of Dried Egg Whites (9 CFR 590.575) Heat treatment of dried whites is an approved method of pasteurization. The product should be heated throughout for the necessary time and temperature that will result in a reduction of Salmonella spp. to undetectable levels. The product for heat treatment should be in closed containers to prevent post-lethality exposure. The containers should be placed in a heat treatment room with adequate spacing between the containers", "19 to assure heat penetration and air circulation so that all product reaches the desired time and temperature combination. Each container should include information on the product type (spray or pan dried) and the production lot number or production code. Former regulatory times and temperatures for heat treatment of spray or pan dried albumen are as follows: \u2022 Spray dried albumen should be heated throughout to a temperature not less than 130\u00b0F and held continuously at such temperature for a minimum of 7 days; or \u2022 Pan dried albumen should be heated throughout to a temperature of not less than 125\u00b0F and held continuously at such temperature for a minimum of 5 days. Cooling Operations (9 CFR 590.530) Table 2 provides the former cooling requirements for liquid egg products. Liquid egg products would be considered satisfactorily cooled only when the entire mass reaches the required temperature. The temperature of

previously cooled product may rise because of further processing operations such as blending, homogenizing, or reconstituting dried products. The temperature must be reduced again to meet the safe harbors. Prior to pasteurization, the liquid egg products listed in Table 2 would need to be brought to the respective temperature within two hours of breaking. Table 2.

Former Cooling and Temperature Requirements for Liquid Egg Products That Could Be Used as Safe Harbors Product Non-Salted Liquid Product to be held 8 hours or less Non-Salted Liquid Product to be held more than 8 hours Salted Liquid Product Temperatures within 2 hours after Pasteurization Temperatures within 3 hours after Stabilization White (not to be stabilized)

The storage of stabilized liquid whites should be limited to that necessary to provide a continuous operation. 2 The cooling process should be continued to assure that any salt product to be held more than 24 hours is cooled and maintained at 45\u00b0F or

lower. Freezing Operations (9 CFR 590.536) Freezing rooms should be kept clean and free from objectionable odors.", "20 \u2022 Non-pasteurized egg products intended for freezing should be solidly frozen or reduced to a temperature of 10\u00b0F or lower within 60 hours from time of breaking. Non-pasteurized frozen egg product would need to be defrosted or tempered (see Defrosting Operations) prior to pasteurization. \u2022 Pasteurized egg products intended for freezing should be solidly frozen or reduced to a temperature of 10\u00b0F or lower within 60 hours from time of pasteurization. The temperature of products not solidly frozen should be taken at the center of the container. Containers should be stacked to allow sufficient air circulation around the containers. The outside of liquid egg containers should be clean and free from evidence of liquid egg, shell, or debris. Frozen egg products should be examined

organoleptically after freezing to determine their fitness for human food. Defrosting Operations (9 CFR 590.539) Frozen egg products which are to be defrosted must be defrosted in a sanitary manner. Frozen egg products should be examined organoleptically prior to defrosting to determine their fitness for human food. Table 3 provides acceptable tempering and defrosting operations for frozen egg products. Table 3. Former Defrosting Requirements for Liquid Egg Products That Could Be Used as Safe Harbors Product Type Temper \u2219 Defrost Option

Temperature Time Special Considerations Dried Albumen Ambient - - For production of dried albumen Egg Products Ambient 40\u00b0F or lower 48 hours or less Liquid product maintained at 50\u00b0F or lower Egg Products Ambient Greater than 40\u00b0F 24 hours or less Egg Products Running Water 70\u00b0F or lower - Plastic or metal container Once the product has been defrosted, it should be maintained at 40\u00b0F or less, unless it is to be pasteurized or stabilized by glucose removal. Defrosted liquid product shall not be held more than 16 hours prior to processing or drying. Control of Pathogens in Egg Products The times and temperatures for destroying Salmonella spp. are dependent upon the type of egg product being produced: egg white, whole egg, or egg yolk, as well as product formulations such as added salt or sugar.

In addition to the former regulatory pasteurization time and temperatures already provided in Pasteurization Operations (9 CFR 590.570), Appendix II and Appendix III provide pasteurization time and temperature tables. Along with eliminating and reducing pathogens during the lethality step, plants also need to control for pathogens after the lethality step by limiting the cross-contamination potential. The subsequent sections provide detailed information for the control of pathogens in each specific product type as well as at the post-lethality step." , "21

Liquid Egg Products Liquid egg products include whites, yolks, whole eggs, blends of whole eggs and yolks, and egg substitutes. Some egg products, such as those containing salt and sugar, may require higher pasteurization times and temperatures. Appendix III includes Tables III.A through III.C that provide different combinations of times and temperatures for 14 different types of liquid egg products, including: plain egg white at four different pH values (7.8, 8.2, 8.8, and 9.3); plain whole egg and plain egg yolk; 10% added sugar or 10% added salt to liquid plain whole egg or to liquid plain egg yolk; and five formulated liquid egg products. Plants should select the option that will allow them to meet the requirements for their specific processes.

Liquid Egg Whites Pasteurization can adversely affect the functional properties of liquid egg whites depending on the time and temperature used. Egg white proteins are particularly susceptible to heat damage and, therefore, require lower heating temperatures (International Egg Pasteurization Manual) to preserve functionality. A 5-log<sub>10</sub> reduction of *Salmonella* spp. in liquid egg whites with lower pasteurization times and temperatures can be achieved by raising the pH. The higher pH values work to reduce the heat resistance of *Salmonella* spp. A recognized bactericidal agent can also be added to liquid egg whites to reduce microbial contamination. It allows for the pasteurization of egg whites at relatively low temperatures (Eskin and Shahidi, 2012). Appendix III, Table III.A provides different combinations of times and temperatures at four different pH values (7.8, 8.2, 8.8, and 9.3) that achieve a 5-log<sub>10</sub> reduction of *Salmonella* and, thus, may be used for egg whites originating from farms that have positive *Salmonella Enteritidis* eggs. Plants can select which time and temperature combination is suitable for their egg products processing operation. For example, a pH of 7.8 at a pasteurization temperature of 140°F and holding time of 21 seconds is needed to ensure adequate pasteurization and that pathogens are non-detectable in *Salmonella Enteritidis*-diverted eggs. For liquid egg products with a lower pH, additional ingredients may be added to improve lethality while preserving the functionality. Chemical reagents and metal ions are commonly added to stabilize the proteins that contribute to the egg white's functionality in cooking and baking. Hydrogen peroxide, a recognized bactericidal agent, can also be added to liquid egg whites to reduce microbial contamination. It allows for the pasteurization of egg whites at relatively low temperatures (Eskin and Shahidi, 2012).

Liquid Whole Eggs Liquid whole eggs often consist of blended non-egg ingredients, including salt, sugar, or corn syrup. These are added to whole eggs to prevent egg yolk gelation during freezing or impart functional properties to the liquid whole egg product. Liquid whole eggs that do not contain blended ingredients may be pasteurized at times and temperatures lower than egg yolks. To use the time and temperature combinations for liquid whole egg products without added ingredients, the plant should refer to Table III.B in Appendix III. For example, 10% salt whole egg at a pasteurization temperature of 150°F requires a holding time of 78 seconds to ensure adequate pasteurization and that pathogens are non-detectable." , "22

Liquid Egg Yolks Liquid egg yolk has a higher viscosity (due to higher fat and protein content) than egg whites, thus

decreasing the lethality of *Salmonella* to heat (Li, et.al., 2005). In addition, *Salmonella* spp. are the most heat resistant at near neutral pH, similar to the conditions of the egg yolk (Eskin and Shahidi, 2012). As a result of the higher viscosity and near neutral pH, *Salmonella* spp. may acquire greater heat-resistance more readily in egg yolk than in egg whites. Hence, the pasteurization for egg yolk is higher and longer than egg whites. Sugar, salt, glycerol, or other similar ingredients are often added at levels of 10 to 15% to reduce the gelation that can occur when freezing liquid egg yolk (Carter, 1968). *Salmonella* spp. are more resistant when salt is added due to lowering of the water activity. Consequently, salted egg yolk requires increased time and temperature for effective pasteurization than non-salted egg yolk (Palumbo, et.al., 1995). Scientific studies have also identified that Lm has a much higher heat resistance in salted egg yolk products (Palumbo et al., 1995; Michalski et al., 2000; Huang, 2019). FSIS has determined that a pasteurization temperature of 155°F with a minimum holding time of 12 to 13 minutes is needed in order to achieve a 5-log<sub>10</sub> reduction of Lm in the 10% salted egg yolk, based on the D-values from three published thermal death time studies (Palumbo et. al., 1995; Michalski et. al., 2000; Huang, 2019). In the past, *Salmonella* has been used as the indicator of lethality because of the association of *Salmonella Enteritidis* foodborne illnesses with eggs and because *Salmonella Enteritidis* can infect the egg during the developmental process inside the chicken (FSIS Risk Assessment, 1998; FSIS Risk Assessment, 2005). FSIS recommends that plants continue to use *Salmonella* as an indicator of effective pasteurization in egg products because the thermal destruction of *Salmonella* in cooked products would indicate the destruction of most other pathogens (64 FR 733). If the plant's scientific support demonstrates that its lethality treatment achieves sufficient reduction in *Salmonella*, it does not need to provide additional support that adequate reduction in other pathogens is achieved. However, if a sample tests positive for Lm, the plant should verify that inadequate lethality was not the root cause as part of its corrective actions (9 CFR 417.3(b)). If reprocessing the adulterated product, the plant would need to repasteurize at 155°F for 12 to 13 minutes or provide alternate scientific support for the pasteurization time and temperature required to achieve a 5-log<sub>10</sub> reduction of Lm. To use the time and temperature combinations for egg yolk products, plants should refer to Table III.C in Appendix III. For example, 10% sugar egg yolk at a pasteurization temperature of 155°F requires a holding time of 17 seconds to ensure adequate pasteurization and that *Salmonella* spp. are non-detectable. Alternatively, plants may choose not to use the tables in Appendix III and implement a customized process that is designed to ensure egg products are edible without additional preparation to achieve food safety. Plants would need to provide adequate scientific support for any processes not provided in this guideline. See the section Scientific Support Available for Lethality Requirements for Egg Products for examples of scientific support." , "23 Dried Egg Products Dried or dehydrated egg products are known as egg solids and typically are spray dried to remove most of the moisture. Dried product that is not subjected to a pasteurization treatment (i.e., dried egg white products) in a liquid state must be subjected to a heat treatment in the dried state that will impart a lethality necessary to ensure pathogens are non-detectable. This section discusses the processing of dried egg white products. Since dried egg yellows are pasteurized first prior to drying, control of pathogens in dried egg yellows is discussed in the sections Liquid Whole Eggs, Liquid Egg Yolks, and Post-Lethality Handling and Sanitation. Lethality models for *Salmonella* were constructed based on a Weibull inactivation

curve using the measured levels reported in the Jung and Beuchat (1999) paper for Salmonella and the USDA Agricultural Research Service. For Salmonella, it was estimated that a product containing 5% moisture requires more than 21 days at  $54^{\circ}\text{C}/129.2^{\circ}\text{F}$  to achieve lethality of  $5.7 \log_{10}$ ; a product containing 8% moisture requires more than 12 days. Other models predicted that even more time would be required to achieve a lethality of  $5.7 \log_{10}$ . Table 4 provides estimates of the minimum number of days at  $54^{\circ}\text{C}/129.2^{\circ}\text{F}$  that would be required to obtain a minimum lethality of  $5.7 \log_{10}$ . The percent moisture described in Table 4 refers to the moisture content at the initial state, at the beginning of pasteurization. For example, a plant places one lot of dried egg whites into the hot room, with the initial percent moisture ranging from 6% to 8%. The dried egg whites would have to be held for the number of days associated with the lowest initial percent moisture level (6%) to meet the minimum lethality of  $5.7 \log_{10}$ ; the lot would have to be held for a minimum of 18 days. Table 4. Estimated Minimum Number of Days at  $54^{\circ}\text{C} / 129.2^{\circ}\text{F}$  to obtain at least a lethality of  $5.7\log_{10}$  for Salmonella spp. in Dried Egg White Product, Based on the Percent Moisture of product before pasteurization.

Percent (%)	Moisture	4	5	6	7	8
Days at $54^{\circ}\text{C}/129.2^{\circ}\text{F}$	26	22	18	15	13	

Likewise, as with liquid egg products, information from challenge studies, published studies, and computer modeling can be used to demonstrate that a process complies with the lethality performance requirements. Plants can also develop alternative lethality protocols for dried egg products based on yield-equivalent-weight (grams) sample which is the specific dried product yield to the liquid product. For example, if 100 mL of liquid egg white product produced approximately 13 grams of dried product, the alternative lethality value would be determined with respect to the 13 grams of dried product rather than 100 mL of liquid product. Post-Lethality Handling and Sanitation Eliminating and reducing pathogens during the lethality step is just part of controlling pathogens. After lethality, plants need to control their processing environment to prevent contamination of product with pathogens from product handling. Although Salmonella contamination in eggs is typically due to", "24 under processing it may also occur due to cross-contamination in the post-lethality environment. Lm contamination can also be a concern if products are exposed post-lethality. Although liquid egg product processes tend to have limited contact with food contact surfaces post-lethality, any opportunity for contact could result in the potential for post-lethality contamination. In one previous case of an Lm positive in a liquid egg product, the investigation identified that there was a leak in the closed pasteurization system that likely led to cross-contamination. In addition, liquid egg products may be exposed post-lethality during the drying process, such as with spray-dried or pan-dried egg product. Sanitary conditions in drying rooms need to be maintained to prevent contamination of the product during drying and collection. Furthermore, plants producing egg substitutes may add color additives to pasteurized egg whites. If this is the case, then the egg substitute product will need to be repasteurized. The addition of an ingredient post-pasteurization presents a hazard in which contamination could occur. Microbiological Sampling and Testing Program Egg product plants are required to conduct pathogen sampling to ensure their HACCP system is functioning adequately and that the products are free from the presence of Salmonella spp. and Lm. The amended 9 CFR 590.580 pathogen reduction standards testing regulation requires that: \u2022 Plants must test to determine that the production of egg products is in compliance with the Egg Products Inspection Act (EPIA) and the egg products inspection regulations. Egg products plants

are required to hold and maintain control of egg products that have been sampled and tested for public health hazards (e.g., *Salmonella* spp.) until the test results become available in accordance with 9 CFR 590.504. \u2022 To verify adequate pasteurization: \u2013 Pasteurized liquid, frozen, and dried egg products, and heat-treated dried egg whites must be sampled and analyzed for the presence of *Salmonella* spp.; \u2013 Testing must be performed in a manner sufficient to verify that the HACCP system is capable of eliminating *Salmonella* spp. and that the system is working; \u2013 As a safe harbor, the frequency of sampling and testing liquid and frozen egg products can be supported by skip lot testing, which is described in Appendix I: Safe Harbor Sampling Rates for *Salmonella* spp. Verification Testing for Liquid and Frozen Egg Products; \u2013 Samples must be analyzed for the presence of *Salmonella* spp. at a frequency and using a laboratory method (see section Microbiological Testing Method) that will ensure that the product is not adulterated (9 CFR 590.580(b)(2)); and \u2013 Samples must be collected from the final packaged form (9 CFR 590.580(b)(3)). \u2022 Plants are not required to analyze for the presence of Lm.", "25 Written Microbiological Sampling Program To meet the regulatory requirements, the plant must develop and implement a written microbiological sampling and testing program. At a minimum, the written sampling program must include: \u2022 A description of the sample collection procedures, including how random sampling is achieved, how the sample is collected, and how samples are handled to ensure sample integrity, and the name or title of the plant employees designated to collect the samples for testing; \u2022 A description of the analytical method used to test the samples and the name and location of the microbiology testing laboratory performing the analysis. The method used should be validated by a recognized independent testing body. Further information can be found in the FSIS Establishment Guidance for the Selection of a Commercial or Private Microbiological Testing Laboratory; \u2022 The microbiological organisms (e.g., *Salmonella* spp.) that the plant will test its samples for to monitor the effectiveness of its process control; \u2022 The locations within the plant\u2019s production process where samples are collected; \u2022 The frequency of sample collection; and \u2022 Scientific and technical documentation to support the design of the sampling program. Further information on scientific and technical documentation can be found in the FSIS Compliance Guideline HACCP Systems Validation.

Microbiological Testing Method Egg products plants should ensure that microbiological testing meets its food safety needs. A plant needs to determine whether sample analysis will be performed by an outside laboratory or in its own laboratory onsite (if available). The test method used should be validated for the target organisms and for the sample matrix being analyzed to ensure accuracy of the results. It should also be a method validated by a recognized independent body, such as the Association of Official Analytical Chemists (AOAC) Official Method of Analysis or International Organization for Standardization (ISO). FSIS has made available a list of Foodborne Pathogen Test Kits Validated by Independent Organizations for the detection of relevant foodborne pathogens (i.e., *Salmonella* spp., *Campylobacter*, Shiga toxin-producing *E. coli*, and *Listeria* spp., including Lm). These lists are intended to be informational and are not an endorsement or approval of any particular method, regardless of its inclusion in the list. A rapid screening method may be used if that method is validated for egg products and is approved by a recognized independent body or the FSIS Rapid Screening Method as described in the Microbiological Laboratory Guidebook. Presumptive positives from the rapid screening methods may", "26 be confirmed using an accepted culture method. If the rapid

screening method is not used, plants may use an accepted cultural method. Accepted culture methods include: \u2022 FSIS Microbiology Laboratory Guidebook, Chapter 4 \u2013 Identification of Salmonella from Meat, Poultry, Pasteurized Egg Products, and Siluriformes Products and Carcass and Environmental Sponges; or \u2022 FDA Bacteriological Analytical Method, Chapter 5 \u2013 Salmonella. For plants electing to use an outside laboratory, FSIS has made available the guidance, Establishment Guidance for the Selection of a Commercial or Private Microbiological Testing Laboratory. This guidance document should be particularly useful to plants when they are selecting a commercial or private laboratory to analyze microbiological samples. Plants should clearly communicate their needs to the testing laboratory and direct them to any necessary testing protocols or other guidance, including this document, on the FSIS Guidance Website. Plants that select a laboratory that does not apply appropriate testing methods or effective Quality Control\Quality Assurance (QC\QA) practices may not receive reliable or useful testing results. For plants electing to maintain their own microbiological testing laboratory, FSIS recommends that the laboratory be segregated from manufacturing areas and that access to the laboratory space be limited to prevent cross-contamination. If the plant will be testing for pathogens onsite, then they should follow requirements for Biosafety Level II laboratory operation as outlined in to ensure food safety and security. Recordkeeping Upon implementation of the sampling program, the plant must maintain records sufficient to document the implementation and monitoring of sample collection to comply with 9 CFR 590.580. It is recommended that records include the testing procedures, including support for the adequacy of the testing frequency, the test results, and other information, such as the: \u2022 Time, date, and location of the sample collection; \u2022 Sample collector\u2019s name; \u2022 Name or description of the product or sample source; and \u2022 Lot information and producer. All entries should be dated and initialed by the sample collector immediately upon completion of the entry. If an outside laboratory is used for testing, then these records should also include information, such as the date the sample was shipped to the laboratory for analysis. The outside laboratory should document the:","27 \u2022 Date received; \u2022 Condition of the sample upon receipt, including sample temperature, if applicable; \u2022 Date the analysis was started and completed; and \u2022 Analytical result. Test results should also be recorded and linked to the sample collection records by a sample number, form number, or some other unique identifier. The testing records: \u2022 Should be maintained in a way that ensures the integrity of the data; \u2022 May be maintained in an electronic format<sup>1</sup>, provided there are measures in place to ensure the security of the information; and \u2022 Should be readily accessible for review by the plant and FSIS IPP upon request<sup>2</sup>. Actions in Response to Test Results Plants are required to test egg products for the presence of Salmonella. In addition, FSIS will collect samples to analyze for Salmonella, Lm, and violative residues<sup>3</sup>. Plants are required to hold or maintain control of lots samples for Salmonella or Lm (meaning, hold the product at the plant or move the product to another location but keep the product under plant control). FSIS recommends but does not require that the plant hold or maintain control of lots sampled for violative residues. If a sample of an egg product tests positive for Salmonella spp., Lm, or a violative residue, FSIS considers the lot adulterated. The section Lotting Practices provides FSIS\u2019s guidance on defining lots. The plant is required to take corrective actions according to 9 CFR 417.3(a) or (b), depending on whether the plant controls the applicable hazard through its HACCP plan or

prevents it through a prerequisite program. \u2022 If product is positive for Salmonella spp. or Lm and the plant does not want to destroy the product, it can be reprocessed with the assurance that the egg product will be rendered free of detectable pathogens. 1 Acceptable electronic formats include scanned images of the original paper records, saved email attachments of laboratory results, etc. It is not acceptable to transcribe original official records to an alternate format, such as Excel, and then discarding the official record. 2 Accessibility of records for IPP review does not mean that plants are required to grant IPP access to the plant computer. 3 On September 21, 2016, FSIS began analyzing all domestic and imported pasteurized egg products that it analyzes for Salmonella spp. and for Lm (as a measure of environmental cleanliness). On September 27, 2018, FSIS began analyzing egg products for residues, such as pesticides.", "28 \u2022 If the product contains a violative residue, the product must be destroyed as reprocessing of the product will not remove the violative residue.

**Lotting Practices**

If either a plant sample or an FSIS sample is found positive for Salmonella or Lm, or found to contain violative levels of residues, the lot representing that sample (henceforth, sampled lot) is considered adulterated. When a sampled lot is found adulterated, multiple lots may be implicated. Proper lotting may be instrumental in reducing the impact of reprocessing product (for Salmonella or Lm positive product) or product recalls (for product that was not held). Lots should be designed so that if the sampled lot was found adulterated, the product in other lots can be deemed independent and not implicated. The sampled lot definition will differ based on microbiological versus chemical analyses. For microbiological analyses, a typical lot can be defined as one day\u2019s production (physically separated pasteurization run) of each type of product. A physically separated pasteurization run means that product has been separated from other production lots by cleaning and sanitizing, such that there is no potential contamination between separate lots of product. This may include cleaning the entire system (pasteurizer, clean-in-place (CIP) lines to packaging room, final packing\filling equipment). The following factors may be considered when FSIS determines what additional lots may be implicated if the sampled lot is found adulterated:

\u2022 Egg products plants are not required to perform a CIP procedure between each lot production. However, if egg products are stored or packaged using common pipelines and equipment that have not been cleaned and sanitized prior to establishing another individual lot, FSIS cannot recognize the product subsequently produced as a separated product lot;

\u2022 Plants may store multiple lots in a common area. The plant must maintain sanitary conditions to prevent contamination of the product(s) during storage and consider possible crosscontamination if products from different lots are stored in the same cooler, freezer, or dry egg products cool storage;

\u2022 Plants may define a lot differently based on the product group. For example, dried egg whites undergo a heat treatment, rather than a pasteurization run. In this case, the sampled lot would be all products present in the same heat treatment room at the same time;

\u2022 Because Salmonella can contaminate final egg products as a result of underprocessing, if one lot of egg product tests positive by FSIS and another lot of product received the same lethality treatment, scientific support is necessary to justify why the later lot should not be implicated; and

\u2022 In addition, some plants may store more than one lot of pasteurized product in one pasteurized egg product silo without conducting a cleanup between lots. When this occurs, FSIS would consider the sampled lot to consist of all co-mingled pasteurized runs.", "29 A plant may reduce its lot size when collecting a microbiological sample, or when FSIS is collecting a microbiological

sample, to facilitate holding the product, as long as the change does not interfere with collecting a representative sample. A reduction of lot size may be accomplished by breaking fewer eggs or pasteurizing smaller amounts of liquid eggs. FSIS is not aware of a mechanism to reduce the lot size of dried egg whites, as fewer boxes in the room would alter heat distribution and no longer reflect normal operations. For chemical analyses, FSIS generally considers the sampled lot to be all products originating from the same poultry farm. In general, poultry management practices result in the entire flock being treated at the same time rather than individually. Most plants may combine egg products from shell eggs coming from multiple poultry farms into a single production run. If this is the case, then all poultry farms represented in a violative-positive production run would be implicated unless the plant can supportably justify the exclusion of certain farms. Plants may reduce the number of farms representing the sampled lot when FSIS is collecting a residue sample. By reducing the number of farms comprising a lot, fewer farms would be implicated if the sample was found violative. In addition, plants may reduce implicated lots by using the sampled lot in only one product type and not combining the sampled lot with egg products from other farms until the results are received. It is up to the plant to determine the size of the lot. New Technologies The amended regulations provide more flexibility for plants to innovate with new technologies that can improve efficiency and food safety. However, there may still be occasion for plants to request a waiver or No Objection Letter (NOL) for certain innovations. Plants may submit a new technology notification and protocol through AskFSIS. In the request, plants should provide data to justify the new technology request. In addition, egg products plants may only use sanitizers and color additives that are recognized as safe and suitable under the conditions of its intended use (such as those listed in FSIS Directive 7120.1, Safe and Suitable Ingredients in Meat, Poultry, and Egg Products and those that are listed in 9 CFR 424.21(c)). If a plant chooses to develop and implement applications that incorporate such substances or ingredients that are not recognized as safe and suitable, then it must apply for an NOL through the new technology notification process. Key Point FSIS recommends that plants use the FSIS Compliance Guideline Procedures for New Technology Notifications and Protocol document, which provides guidance concerning the procedures for preparing and submitting a new technology notification and protocol to FSIS." "32 Appendix I: Safe Harbor Sampling Rates for *Salmonella* spp. Verification Testing for Liquid and Frozen Egg Products Liquid and Frozen Egg Products Sampling of lots for each product category will begin at the 100 percent frequency level unless or until a history of compliance has been established (60 consecutive lots are *Salmonella* spp. negative). For each category, one type of product will be identified for sampling each production day on a rotation basis. (Each product within a category does not need to be sampled every day). \u2022 100 percent sampling (No history of compliance for a category) \u2013 every lot must be sampled until 60 consecutive lots are found to be *Salmonella* spp. negative. \u2022 Level 1 \u2013 1 lot sampled for every 2 lots produced. \u2022 Level 2 \u2013 1 lot sampled for every 4 lots produced. \u2022 Level 3 \u2013 1 lot sampled for every 8 lots produced. Reducing the Sampling Frequency To reduce the sampling frequency:

1. From 100 percent to Level 1: 60 consecutive lots within a product category must be *Salmonella* spp. negative.
2. From Level 1 to Level 2: 60 sampled lots within the product category must be *Salmonella* spp. negative.
3. From Level 2 to Level 3: 60 sampled lots within the product category must be *Salmonella* spp. negative.

NOTE: Plants currently sampling under one of the three reduced sampling levels may maintain that level until sampling results indicate that an increase in sampling frequency is required or that the sampling frequency may be further reduced.

Action Required for *Salmonella* spp. Positive Lots

1. If a *Salmonella* spp. positive4 lot is found at any of the 3 reduced sampling levels, the plant must immediately begin sampling the entire product category at 100 percent.
2. See the section, titled \u201cMicrobiological Testing Methods\u201d for information on the expectations of test method choices.
3. Once 60 consecutive lots of that product are *Salmonella* spp. negative, sampling frequency may resume at the level attained before the positive was found.

However, if the product initially identified as *Salmonella* spp. positive is not sampled during those 60 consecutive lots, the next lot produced of that product must be sampled.

3. If 2 lots within the same category are found to be *Salmonella* spp. positive within a 12-month period, the plant must return to the 100 percent sampling level for that category.
- Once 60 consecutive lots are *Salmonella* spp. free, the plant must then satisfy the requirements for both Level 1 and Level 2 before moving to Level 3.

Required Records

The egg products inspection regulations require a plant to maintain records for each lot of product produced. Records must be maintained for at least 1 year for refrigerated products and 2 years for frozen, preserved, or shelf-stable products and must be available to FSIS program employees upon request. Records must contain the following information:

- \u2022 Type of product, category, and lot number of each product lot;
- \u2022 Number, net weight, and type of containers in each lot, (e.g., 125 30-pound can; 250 30-pound cases (6 5-pound cartons));
- \u2022 For each lot sampled, the lot

number, date sampled, number of samples collected, portion of the lot from which the sample(s) was taken (i.e., container number, pallet number, etc.) and the sampling level for that category of product; \u2022 Individual sample results; and the \u2022 Name and location of the recognized laboratory performing the analyses.", "34 Figure I.A. Egg Products Sampling Flow Diagram NOTE: Plants without a sampling history or plants producing a new product category begin sampling at the 100% sampling frequency. Plants currently at one of the three reduced frequencies may maintain that frequency until sampling results indicate that an increase in sampling frequency is required, or that the sampling frequency may be further reduced. 100% Sampling 60 Consecutive Lots Plants with no sampling history or that receive 2 or more positive results Level 1 - 1 of 2 Lots 60 Consecutive Lots 100% Sampling of 60 Consecutive Lots Level 2 - 1 of 4 Lots 60 Consecutive Lots 100% Sampling of 60 Consecutive Lots Level 3 - 1 of 8 Lots All Sampled Lots 100% Sampling of 60 Consecutive Lots Any Positive Any Positive Any Positive Second Positive Second Positive Second Positive", "35 Appendix II: New Technology Pasteurization and Freezing Time and Temperature Tables Under the former regulations, plants had submitted protocols to implement alternate procedures and waive the prescriptive regulatory requirement. The protocols from those waivers and NOLs have been incorporated in the tables below as additional options for plants to use as safe harbors. The following tables include various product formulations for egg whites, whole egg, egg yolk, and enzyme modified egg products and their respective approved pasteurization time and temperature parameters, as well as alternate freezing parameters.", "36 Table II.A. Introduction.....1  
Quick Reference Table of Process Steps in Alphabetical Order by Product Category.....2  
Suggested General VerificationQuestions for Most Process Steps.....3  
Process Steps, Potential Hazards, and Frequently Used Controls.....4  
i","Introduction FSIS developed this Guide to help FSIS personnel conduct a systematic  
evaluation of processes used in the production of egg products. The Guide identifies relevant

process steps, lists potential hazards for each of these process steps, and cites controls frequently used by processors to address these hazards. Using this Guide, FSIS personnel should be able to verify more effectively that an egg products plant's food safety system is adequately identifying and controlling the hazards associated with its operations. This Guide should be used with the following principles in mind:

- This Guide is not intended to suggest where Critical Control Points (CCPs) should be incorporated in a plant's HACCP system.
- The statement "common hazard" in the Guide is based on the information that is currently available and may change based on research or outbreak and recall investigations.
- Unforeseen hazards and the results of HACCP system reassessments may also identify a possible hazard in a process step where none was previously identified.
- The potential hazards listed may not be the only possible hazards for a particular process step.
- The entries in the "Frequently Used Controls" column are not the only valid controls that plants may include in their HACCP systems for a particular hazard.
- A set of suggested general and process-specific verification questions are included in this Guide after each process step listed. These questions are intended to guide FSIS personnel when evaluating a plant's HACCP system and specifically its process steps and to trigger additional questions. It is important for FSIS personnel to realize that these questions are not meant to be all-inclusive, but to provide examples of the types of questions that may arise when verifying the adequacy of a plant's HACCP system and regulatory compliance.
- This Guide should also be useful to plant personnel, particularly those in small and very small plants. However, the potential hazards and frequently used controls listed in this Guide are neither the only possible hazards nor the only applicable process controls available to a plant operator. Each plant must design its HACCP system to address those hazards that are reasonably likely to occur in its own specific production processes.

The Guide consists of the following major sections:

- Quick reference table of process steps in alphabetical order for the most common process steps in the production of egg products;
- General verification questions for most process steps; and
- A listing of individual process steps with currently identified potential hazards and frequently used controls.

1", "Quick Reference Table of Process Steps in Alphabetical Order by Product Category Process Steps Page No. Raw\NRTE RTE Not Shelf Stable RTE Shelf Stable Blending of dry ingredients into dried egg product 19 \u2022 Breaking and separating of eggs 10 \u2022 Classification and sorting, handling, and transfer of shell eggs 8 \u2022 Defrosting 12 \u2022 \u2022 Desugaring\fermentation 15 \u2022 \u2022 Egg washing\sanitizer 9 \u2022 Formulation\mixing\homogenization\reconstitution of dried product 13 \u2022 \u2022 Freezing 20 \u2022 \u2022 Heat treatment of dried egg whites 17 \u2022 Liquid egg cooling and holding 11 \u2022 \u2022 Packaging\repackaging 22 \u2022 \u2022 \u2022 Pasteurization 14 \u2022 Receiving and storage of packaging materials and non-egg ingredients 7 \u2022 \u2022 \u2022 Receiving and storage of raw\NRTE liquid egg products 5 \u2022 Receiving and storage of RTE egg products (liquid\dried) 6 \u2022 \u2022 Receiving and storage of shell eggs prior to use 4 \u2022 Rework 18 \u2022 \u2022 \u2022 Shipping 24 \u2022 \u2022 \u2022 Sifting of dried egg products 21 \u2022 \u2022 Spray\pan drying (yellow\white) 16 \u2022 Storage, handling and loading of egg product after packaging and prior to shipping 23 \u2022 \u2022 \u2022 2", "Suggested General Verification Questions for Most Process Steps The following set of general questions should be used by FSIS personnel when evaluating and assessing the adequacy of a plant's hazard analysis and its decision

making for each process step relative to potential hazards, controls for identified hazards, monitoring and recordkeeping. This Guide also includes more specific questions for each process step under the Process Steps, Potential Hazards, and Frequently Used Controls section that FSIS personnel can use to assist with their evaluation of the adequacy of a plant's HACCP system. Has the plant included this process step in its flow chart and hazard analysis? Does the plant have a prerequisite program that addresses this process step? Has the plant identified any hazards associated with this process step? Is this process step a CCP? Is the plant following procedures to eliminate or reduce any identified hazard? Can the plant support that the hazard is not reasonably likely to occur (NRLTO)? Did the plant validate the control methods, including preventive measures and prerequisite programs, for this hazard? Does the plant have in-plant validation data for 90 calendar days to support that the control is working as intended? (NOTE: The documentation for in-plant validation from small and very small establishments may contain data from greater than 90 calendar days if a request is granted in writing by the district office for additional calendar days to gather records to cover at least 13 production days.)

Is the plant following all procedures (i.e., prerequisite or other programs) identified in its hazard analysis? Does the plant maintain records associated with this process step? Do records contain information that indicates a reassessment of the hazard analysis necessary? Are records made available to FSIS? Is the equipment used clean, sanitary, and well maintained?

**3", "Process Steps, Potential Hazards, and Frequently Used Controls Process Step Potential Hazards Frequently Used Controls Receiving and storage of shell eggs prior to use Note:** Shells eggs intended for breaking must be transported and stored at or below 45°F ambient temperature beginning 36 hours after time of lay (21 CFR 118.4(e)).

**Biological\u2014Presence and outgrowth of Salmonella (interior and exterior of egg)**

**Pre-harvest:** Eggs handled by the source plant or farm in a manner that minimizes the possibility of pathogen contamination or outgrowth prior to acceptance (e.g., quality assurance programs, letters of guarantee, product temperature tracking, and delivery verification systems). Proper sanitation of equipment (e.g., egg conveyor systems or containers/flats) for in or off-line systems to reduce contamination. Shell eggs held at temperatures for durations that will minimize pathogen growth if contamination is present. This includes the time and temperature held prior to receipt by the processor.

**Chemical\u2014Residues (e.g., pesticides, antibiotics)**

**Physical\u2014No common hazard Suggested verification questions:** 1. Are shell eggs received held under refrigeration? 2. Are the shell eggs stored in a manner that protects them from environmental contamination? 3. How does the plant ensure residues are not present in shell eggs above legal tolerances?

**4", "Process Step Potential Hazards Frequently Used Controls Receiving and storage of raw\NRTE liquid egg products**

**Biological\u2014Presence and outgrowth of Salmonella**

**Product properly handled prior to acceptance (e.g., letters of guarantee, product temperature records).**

**\u2022 Proper receiving temperatures that will minimize pathogen growth.**

**\u2022 Maintain package and product integrity.**

**Chemical\u2014Allergens, residues (e.g., Letters of guarantee; approved pesticides, antibiotics) supplier program.**

**\u2022 Proper storage to prevent crosscontamination of allergen-free products.**

**\u2022 Separate equipment.**

**\u2022 Allergens properly identified in the ingredients statement on the finished product label.**

Physical\u2014Foreign material (e.g., metal, plastic, rubber) \u2022 Visual inspection; proper storage; sieves, filters. Suggested verification questions: 1. Are raw\NRTE liquid egg products received and held under refrigeration to preclude the growth of pathogens? 2. Is container integrity maintained to protect the raw\NRTE liquid egg products from environmental contamination such as dust, moisture, or other physical contaminants? 3. Does the plant address foreign material in its HACCP system? 4. Does the plant receive inedible egg products? If yes, are they handled in a manner that ensures adequate segregation and are inventory controls maintained? 5. Does the plant maintain communication with its suppliers concerning formulation changes or its suppliers\u2019 allergen control programs? 6. If the finished product contains non-egg allergens, does the final product label declare these allergens? 7. How does the plant ensure residues are not present in raw\NRTE liquid egg products above legal tolerances? 5", "Process Step Potential Hazards Frequently Used Controls Receiving and storage of RTE egg products (liquid\dried) Biological\u2014Potential for contamination with Listeria monocytogenes and Salmonella in post-lethality exposed RTE egg products \u2022 Proper sanitation (e.g., separation of raw and RTE product, product or environmental testing). \u2022 Product handled in a sanitary manner during storage and processing (e.g., product temperature, minimize cross-contamination). \u2022 Keep product at time\temperature combinations that will minimize pathogen growth. \u2022 Maintain package and product integrity; letters of guarantee. Chemical\u2014Allergens, residues (e.g., \u2022 Letters of guarantee; approved pesticides, antibiotics) supplier program. \u2022 Proper storage to prevent cross-contamination of allergen-free products. \u2022 Separate equipment. \u2022 Allergens properly identified in the ingredients statement on the finished product label.

Physical\u2014Foreign material (e.g., metal, plastic, rubber) \u2022 Visual inspection; proper storage; sieves, filters. Suggested verification questions: 1. Are the RTE egg products (liquid) received held under refrigeration or frozen to preclude the growth of pathogens? 2. Is container integrity maintained to protect these types of egg products from environmental contamination such as dust, moisture, or other physical contaminants? 3. Does the plant have a sanitation program to address Listeria monocytogenes and Salmonella in the post-lethality exposed environment? 4. If the product contains non-egg allergens, does the final product label declare all allergens? 5. Does the plant address foreign material in its HACCP system? 6. Does the plant have controls to prevent cross-contamination of RTE egg products with raw (i.e., unpasteurized) product? 7. Does the plant maintain communication with its suppliers concerning formulation changes or its suppliers\u2019 allergen control programs? 8. How does the plant ensure residues are not present in RTE egg products above legal tolerances? 6", "Process Step Potential Hazards Frequently Used Controls Receiving and storage of packaging materials and non-egg ingredients Biological\u2014Contamination with pathogens (e.g., Salmonella or Listeria monocytogenes) \u2022 Letters of guarantee. \u2022 Packing materials and non-egg ingredients are transported and stored in a manner that ensures product integrity and proper conditions are maintained. \u2022 Dry goods are protected from pests and environmental contamination. Chemical\u2014Allergens \u2022 Letters of guarantee; approved supplier program. \u2022 Proper storage to prevent cross-contamination of allergen-free products. \u2022 Separate equipment\tools (e.g., shovels) for products containing allergens. \u2022 Allergens properly identified in the ingredients statement on the finished product label.

Physical\u2014Foreign material (e.g., \u2022 Visual inspection for foreign metal, plastic)

material. \u2022 Protect packaging materials from environment. Suggested verification questions: 1. Are materials and ingredients guaranteed by the manufacturer? 2. Are materials and ingredients protected from environmental contamination, e.g., are containers kept closed, properly identified and properly stored in acceptable storage areas? 3. Does the plant maintain communication with its suppliers concerning formulation changes or its suppliers\u2019 allergen control programs? 4. If the finished product contains non-egg allergens, does the final product label declare all allergens? 5. For non-egg ingredients added post-lethality, can the plant support the safetyof these ingredients(i.e., free of pathogens and unintended allergens)foreach lot of product? 7", "Process Step Potential Hazards Frequently Used Controls Classification and sorting, candling, and transfer of shell eggs Biological\u2014Presence of Salmonella \u2022 Restricted orineligible eggs are properly segregated; eggs with strong odors are candled and broken separately, and then assessed for acceptability. \u2022 Soiled eggs are segregated for resorting and rewashing. \u2022 Proper cleaningof the transfer room equipmentand effective Sanitation Standard Operating Procedures (Sanitation SOPs). \u2022 Protections from environment. Chemical\u2014No common hazard Physical\u2014No common hazard Suggested verification questions: 1. Are shell eggs sorted andclassified into categoriesas requiredin9 CFR 590.510? 2. Are shell eggs having strong odors or eggs received in cases having strong odors candled and broken separately to determine acceptability? 3. Are ineligile and restricted shell eggs properly segregated? 4. Are candling devices designed to adequately determine the interior condition of shell eggs? 5. Are containers, shell egg conveyors, and floors constructed in a manner to allow thorough cleaning and disinfection? 8", "Process Step Potential Hazards Frequently Used Controls Egg washing\u2014sanitizer Biological\u2014Salmonellasurvival \u2022 pH of wash water\u2014concentration of sanitizer is monitored, recorded, and maintained at a level to maximize bactericidal effect on exterior of shell. \u2022 High-temperature wash water, maintain temperature differential between wash water and internal shell egg temperature. \u2022 Wash waterqualitymaintainedto minimize cross contamination of product. \u2022 Equipment operatingproperly (e.g., spray nozzles, brushes, pumping system, continuous reservoir over flow). \u2022 Proper personalhygiene in place. Chemical\u2014Inappropriate use ofegg \u2022 Egg washing compounds are safe washing or sanitizingagent and effective under the conditions of use; used according to the intended use specified in FSIS Directive 7120.1. \u2022 Equipment is operatingproperly (e.g., sanitizer spray nozzles, pumping system). \u2022 Sanitizers are used according to the intended use specified in FSIS Directive 7120.1. Physical\u2014No common hazard \u2022 Protections from environment are in place. Suggested verification questions: 1. Is egg washing equipment kept in good repair and operated in a manner to ensure eggs are free of visible contaminants after washing? 2. Are cleaning compounds used in the wash wateror egg shell sanitizers,safe and effective, under the conditions of use per FSIS Directive 7120.1, Safe and Suitable Ingredients Used in the Production of Meat, Poultry and Egg Products? 3. Does the plant have supporting documentation for the critical operating parameters1(to include pH, temperature, concentration, and duration of contact) of the wash water or egg shell sanitizer? 4. Is there a functional, adequate exhaust systemin use to reduce odors? 1 Critical operational parameters are the specific conditions that the intervention must operate under in order for it to be effective. For more information see FSIS Compliance Guideline HACCP SystemsValidation. 9", "Process Step Potential Hazards Frequently Used Controls Breaking and separatingof eggs

Biological\u2014Presence and outgrowth of Salmonella \u2022 Sanitation SOPs address proper cleaning and sanitation of room and equipment. \u2022 Proper personalhygiene and practices are in place. \u2022 Proper air movement to allow for organoleptic inspection of broken eggs for wholesomeness. \u2022 Use of sanitizers, frequency of equipment cleaning, and control of room temperature adequate to inhibit growth of pathogenic bacteria on food contact surfaces. \u2022 Ineligible eggs are prevented from entering the breaking room; line speed is adjusted to maintain process control. Chemical\u2014Cleaning chemicals and sanitizers \u2022 Sanitation SOPs address proper cleaning, sanitation, and use of cleaning chemicals\ compounds.

Physical\u2014Foreign material (e.g., \u2022 Liquid egg pumps and shell filters egg shell fragments) workingproperly. \u2022 Breaking equipment is properly adjusted to minimize shell fragmentation. Suggested verification questions: 1. Does theegg breaking roomhave adequate lightingfor visual inspection? 2. Is ventilation in the egg breaking room adequate to prevent product adulteration, control odors, and control condensation to provide for adequate organoleptic inspection? 3. Are eggsthat are ineligible for breaking (e.g., dirty, rots, moldy eggs, etc.) prevented from entering the breaking room? 10", "Process Step Potential Hazards Frequently Used Controls Liquid egg cooling and holding Biological\u2014Raw\NRTE products\outgrowth of Salmonella; RTE products\cross-contamination from raw products andoutgrowth of pa thogens (Salmonella and Listeria monocytogenes) \u2022 Maintain product at time\temperature combinations tha t minimize pathogen growth.

Chemical\u2014No common hazard \u2022 Maintain protection from environment.

Physical\u2014No common hazard Suggested verification questions: 1. Do liquid cooling units have sufficient capacity to cool all liquid eggs? 2. Are liquid egg holding tanks or vats equipped with suitable thermometers and agitators? 3. Are RTE liquid holding silos only vented back into a processing room for RTE product? 11", "Process Step Potential Hazards Frequently Used Controls Defrosting Biological\u2014Raw\NRTE products\outgrowth ofSalmonella; RTE products\cross-contamination from raw products and outgrowth of pathogens (Salmonella and Listeria monocytogenes) \u2022 Control environment. \u2022 Time and temperature. Chemical\u2014No common hazard \u2022 Maintain protection from environment. Physical\u2014No common hazard Suggested verification questions: 1. Are defrosting tankskept in good repair and constructedof material(s) thatfacilitate thorough cleaning? 2. Iseach container of frozen eggs checked for condition and odor just prior to being emptied into crusher or receiving tank? 3. Are crushers and other equipment used in the defrosting operation dismantled at the end of each shift and washed, rinsed, and sanitized? 4. Is the process performed at temperatures that preclude pathogen growth? 12", "Process Step Potential Hazards Frequently Used Controls Formulation\mixing\ homogenization\reconstitution of dried product Biological\u2014Outgrowth of pathogens in rawproducts (e.g., Salmonella); contamination from equipment or ingredientsin RTE products \u2022 Maintain product at time\temperature combinations that minimizepathogenoutgrowth in raw products. \u2022 Sanitation SOPs address proper cleaning and sanitation of room and equipment. \u2022 Ingredients are acceptable under conditions of use (e.g., letters of guarantee). \u2022 Proper personalhygiene. \u2022 Good manufacturing practices and proper processing procedures (e.g., ingredients are properly weighed,labeled, andstored). \u2022 Dusting of dried productis minimized. Chemical\u2014Cross-contamination \u2022 Allergens properly identified in with allergens the ingredients statement on the finished

product label. Products containing allergens are processed and stored separately from allergen-free products. Physical No common hazard Suggested verification questions: 1. Does the plant's Sanitation SOPs or other program address the potential for crosscontamination of pathogens in RTE products? 2. Are ingredients being used in the actual formulation in amounts that agree with the plant's documented formulation for the particular product? 3. Is reworked product included in product formulations? If yes, see rework process step. 4. Are all ingredients being used in actual formulation included in product formula and listed in descending order of predominance that agrees with the ingredient statement on the approved label for the product? 5. Are products that contain allergens processed and stored in a manner to prevent crosscontamination of allergen-free products? 13", "Process Step Potential Hazards Frequently Used Controls Pasteurization Biological Survival of pathogens (e.g., *Salmonella* or *Listeria monocytogenes*), due to insufficient time\temperature lethality treatment \u2022 Effective and validated time\temperature combinations to destroy pathogens. (Note: *Listeria* may become heat-resistant in some products and require an increased time\temperature combination to achieve lethality). \u2022 pH of product maintained to maximize efficacy of lethality treatment. \u2022 Processing aids (e.g., hydrogen peroxide) are used in accordance with approved methodology. \u2022 Equipment maintained and operating properly. \u2022 Proper cleaning procedures in Sanitation SOPs. Chemical No common hazard \u2022 Protection from environment.

Physical No common hazard Suggested verification questions: 1. Is the temperature of liquid egg product continuously and automatically recorded during process? 2. Are holding times and temperatures adequate? 3. If ready-to-eat (RTE) pasteurized egg products are processed using a validated process, are verification activities included as part of the permanent record? 4. Are pasteurized products sampled and analyzed for the presence of pathogens per 9 CFR 590.570? Are records of pathogen testing maintained for the products? 14", "Process Step Potential Hazards Frequently Used Controls Desugaring\fermentation Biological Outgrowth of *Salmonella* and other bacteria during fermentation due to elevated processing temperatures \u2022 Proper cleaning procedures, visual inspection, and effective Sanitation SOPs. \u2022 Proper incubation temperature. \u2022 Letters of guarantee from suppliers of culture. Chemical No common hazard \u2022 Sanitation SOPs address proper cleaning, sanitation, and chemical use. Physical No common hazard \u2022 Equipment maintained and operating properly. Suggested verification questions: 1. Does the plant conduct microbiological testing of ingredients? 2. Does the plant conduct microbiological testing of finished products? 3. Are cultures used at manufacturer's recommended levels? 4. Are product temperatures monitored throughout the process? 15", "Process Step Potential Hazards Frequently Used Controls Spray drying o Yellow (RTE) o White (raw\NRTE) Note: egg whites can be spray or pan dried Biological Potential for contamination with *Listeria monocytogenes* in RTE products \u2022 Continuous discharge to prevent accumulation of powder in dryer. \u2022 Spray or pan-dry parameters are within specifications (e.g., vacuum, temperature, humidity). \u2022 Proper cleaning procedures, visual inspection, and effective Sanitation SOPs. \u2022 Proper maintenance of equipment. Chemical No common hazard Physical Foreign material contamination (e.g., metal) Suggested verification questions: 1. Are drying room facilities and equipment sufficient to preclude adulteration of product? 2. Does the plant control\prevent the buildup of product residues inside the dryer

chambers? 3. Does the plant's Sanitation SOPs or other program address the potential for crosscontamination of pathogens in RTE products? 16", "Process Step Potential Hazards Frequently Used Controls Heat treatment of dried egg whites Biological\u2014Survival of Salmonella \u2022 Effective and validated time\temperature combinations to destroy pathogens. \u2022 Adequate spacing of product to allow heat penetration and air circulation. Chemical\u2014No common hazard Physical\u2014No common hazard Suggested verification questions: 1. Are dried egg whites that have been heat treated in the dry form sampled and analyzed for the presence of Salmonella? Is the sample collected from the center of the package? 2. Does the plant have a valid method for ensuring that the location for monitoring accurately reflects all product in the room? 3. Are records of pathogen testing maintained for the products? 17", "Process Step Potential Hazards Frequently Used Controls Rework Biological\u2014Raw\NRTE products\u2014outgrowth of Salmonella; RTE products\u2014cross-contamination from raw products and outgrowth of pathogens (Salmonella and Listeria monocytogenes) \u2022 Maintain product at appropriate temperatures to control growth of microorganisms. \u2022 Lotting program; effective Sanitation SOPs. \u2022 Proper personal hygiene and adherence to established processing procedures. Chemical\u2014Allergens \u2022 Proper cleaning procedures, visual inspection, and effective Sanitation SOPs. \u2022 Separate equipment. \u2022 Allergens are properly declared on the finished product label. Physical\u2014Foreign material contamination (e.g., metal and other physical contaminants) \u2022 Proper maintenance of equipment. \u2022 An appropriate screening procedure. Suggested verification questions: 1. Are egg products to be used for rework properly stored to preclude pathogen growth and contamination? 2. Are there any hazards associated with rework that are different than hazards associated with the product it is being added to? 3. Does the plant have any additional controls for reworked product (i.e., length of time in storage, results of examination when received)? 4. Does the plant conduct microbiological testing of reworked product? 5. Are all ingredients of the reworked product declared on the label of the finished product, and are they listed in the correct order of predominance? 6. If the finished product contains non-egg allergens, does the final product label declare all allergens? 7. Does the reworked product include returned product (e.g., rejected tanker loads), and if so, does the establishment have a procedure for ensuring the safety of the product? 18", "Process Step Potential Hazards Frequently Used Controls Blending of dry ingredients into dried egg product Biological\u2014Contamination with pathogens from ingredients (e.g., Salmonella and Listeria monocytogenes) \u2022 Letters of guarantee. \u2022 Non-egg ingredients are acceptable for intended use. \u2022 Proper cleaning procedures and effective Sanitation SOPs. Chemical\u2014Allergens \u2022 Established formulation and mixing procedures for restricted ingredients (e.g., silicon dioxide, silicoaluminate, monosodium phosphate). \u2022 Ingredients and chemicals separated, properly labeled, and stored in designated areas. \u2022 Allergens are properly declared on the finished product label. Physical\u2014Foreign material (e.g., equipment parts\pieces) \u2022 Proper maintenance of equipment for proper functioning (e.g., flow meters, pumps, scales). Suggested verification questions: 1. Is blending done in a room separate from other processing operations to prevent crosscontamination of other processing areas? 2. Is all blending and packaging equipment constructed without open seams and of materials that can be kept clean and that will have no deleterious effect on the product? 3. Are blending facilities sufficient to preclude adulteration of

productto include post-lethality contamination, if applicable? 4. If thefinished product contains non-egg allergens, does the final product label declare all allergens? 19", "Process Step Potential Hazards Frequently Used Controls Freezing(liquid products) Biological\u2014No common hazard \u2022 Product is frozen (i.e., time\temperature). \u2022 Freezer equipmentkept in good condition and properly functioning. Chemical\u2014No common hazard \u2022 Proper maintenance of equipment (e.g., pipes, valves maintained to prevent ammonia leak).

Physical\u2014No common hazard Suggested verification questions: 1. Are freezing rooms clean and free of objectionable odors? 2. Are containers stacked so as to permit circulation of air around the containers? 3. Are the egg products stored in a manner that protects them from environmental contamination? 20", "Process Step Potential Hazards Frequently Used Controls Siftingof dried egg products Biological\u2014Contamination with Listeria monocytogenes in RTE products \u2022 Proper cleaning proceduresand effective Sanitation SOPs. Chemical\u2014No common hazard Physical\u2014Foreign material (e.g., screens or parts of broken equipment) \u2022 Maintenance and proper functioningof equipment (e.g., sifter screens are in place and in good repair). Suggested verification questions: 1. Are sifters of such material and construction to facilitate thorough cleaning and to ensure that their use will not cause the adulteration of product during processing to include post-lethality contamination, if applicable? 21", "Process Step Potential Hazards Frequently Used Controls Packaging\repackaging Biological\u2014Contamination with Salmonella and Listeria monocytogenes in post lethality exposedRTE products at time of packaging \u2022 Adequate packaging material. \u2022 Good employee hygiene and product handling procedures. \u2022 Use of HEPA filters and UV lights on packaging equipment. \u2022 Maintenance of packaging equipment andproper sealing of finished product containers. \u2022 Proper sanitationof packaging equipment (e.g., spray nozzles) and implementation of Sanitation SOPs. \u2022 Package integritymaintained.

Chemical\u2014Allergens; packaging not \u2022 Letters of guarantee from appropriate for direct product manufacturer. contact \u2022 Proper cleaning procedures, visual inspection, and effective Sanitation SOPs. \u2022 Separate equipment to prevent cross-contamination by allergens from another formulation. \u2022 Allergens are properly declared on product labeling. Physical\u2014No common hazard Suggested verification questions: 1. Are direct contact packaging materials backed by the supplier\u2019s letter of guarantee? 2. Are packaging materials properly stored and protected from environmental contamination? 3. Are the plant\u2019s SanitationSOPs sufficient to prevent direct contamination and adulteration of egg product in the post-lethality environment? 4. Are egg products handled in a manner that prevents contamination with pathogens and allergens? 5. Does the plant conduct microbial testing of repackaged lots? 6. If the finished product contains non-egg allergens, does the final product label declare these allergens? 22", "Process Step Potential Hazards Frequently Used Controls Storage, handlingand loadingof egg productprior to shipping o Liquid\Refrigerated o Frozen o Dried Biological\u2014Contamination and outgrowth of pathogens during storage and loadingof tankers (e.g., Salmonella and Listeria monocytogenes) \u2022 Maintenance ofproduct at appropriate temperatures to control growth of microorganisms. \u2022 Maintenance ofrefrigeration and freezer equipment and rooms. \u2022 Sanitation SOPs address cleaning and sanitizingof bulk containers (i.e., tankers). \u2022 Separate equipment used for RTE and raw\NRTE liquid egg products. Chemical\u2014No common hazard \u2022 Maintenance ofpackage integrity. \u2022 Sanitation SOPs address finished product handling (e.g., cleaning

and sanitizing tankers and transport vehicles). Physical\ufe0fNo common hazard Suggested verification questions: 1. Are egg products properly refrigerated and not held in areas without refrigeration? If the product is held in areas without refrigeration, does the plant provide supporting documentation for the time and temperature that the product is held? 2. Are liquid-refrigerated\frozen\dried egg products protected from environmental contamination such as dust, moisture, or other physical contaminants? 3. Does the plant address cleaning and sanitizing of tankers in their Sanitation SOPs? 4. Does the plant\ufe0f Sanitation SOPs or other program address the potential for crosscontamination in post-lethality exposed RTE egg products? 23","Process Step Potential Hazards Frequently Used Controls Shipping Biological\ufe0fOutgrowth of pathogens during transport (e.g.,Salmonella and Listeria monocytogenes) \ufe0f Monitor product temperatures during transport. \ufe0f Ensure refrigeration units in transport vehicles, if present,are working properly. Chemical\ufe0fNo common hazard \ufe0f Maintain package integrity. Physical\ufe0fNo common hazard Suggested verification questions: 1. Are egg products properly refrigerated and not held in areas without refrigeration? If the product is held in areas without refrigeration, does the plant provide supporting documentation for the time and temperature that the product is held? 2. Are egg products protected from environmental contamination such as dust, moisture, or other physical contaminants? 24"]},{"file\_name":"FSIS\_GD\_2020\_0009","title":"A Sanitation Standard Operating Procedure Model","num":"FSIS-GD-2020-0009","id":"4e922606a33a958b527ac109609e3419ffe28fc6080c5deba699f2fb5a4f8886","corp\_us":"fsis\_guidelines","source\_page\_url":"https://www.fsis.usda.gov/policy/fsis-guidelines","url":"https://www.fsis.usda.gov/sites/default/files/media\_file/2021-03/Sanitation-SOP-Guide.pdf","type":"pdf","n\_pages":16,"word\_count":4119,"text\_by\_page":["Sanitation Standard Operating Procedures Sanitation Standard Operating Procedures (Sanitation SOPs) are written procedures that an establishment develops and implements to prevent direct contamination or adulteration of product. The establishment is required to maintain these written procedures on file, and they must be available to FSIS upon request. The establishment is required to implement the procedures as written in the Sanitation SOPs. The establishment must maintain daily records sufficient to document the implementation and monitoring of the Sanitation SOPs and any corrective action taken. When the establishment or FSIS determines that the Sanitation SOPs may have failed to prevent direct contamination or adulteration of product, the establishment must implement corrective actions that include the appropriate disposition of product, restore sanitary conditions, and develop measures to prevent recurrence. These written Sanitation SOPs must contain the procedures the establishment will conduct before and during operation; the frequency with which each procedure is to be conducted; the establishment employee or position responsible and be signed and dated by the individual with overall authority. FSIS developed the Sanitation SOP model for establishments to use as a reference when developing Sanitation SOPs. The model was designed to assist establishments in applying the sanitation requirements to their operations and to meet the regulatory requirements of Part 416\ufe0fSanitation. The sanitation model is not intended to be used \ufe0fcas is\ufe0fd for industry Sanitation SOPs. Sanitation SOPs will vary from one establishment to another because each facility will have its own processes that likely differ from that of another. An establishment must tailor the model to suit the specific

circumstances of its own products, production processes and facilities. All elements of the model (e.g., frequencies, monitoring activities, corrective actions, and forms) must be modified (elements added or removed) to reflect the establishment's products, production systems and facilities. This Sanitation SOP is for illustrative purposes only. Page 1 of 16", "A Sanitation Standard Operating Procedure Model This document provides an overview of the Sanitation Standard Operating Procedures (Sanitation SOPs) requirements, a Sanitation SOP model (Attachment 1), and the complete text of the regulations cited in the document (Attachment 2). This information is to assist small and very small official establishments<sup>2</sup> in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Parts 416.11  
416.17.3 The Sanitation SOP model is for demonstration purposes only. The model demonstrates how an establishment might develop Sanitation SOPs to meet the regulatory requirements of 9 CFR 416.11  
416.17. The text and formatting used in the model do not represent requirements that must be met. The use of headings, numbered lists, and tables (forms) are not requirements that must be met. Establishments are required to develop Sanitation SOPs specific to their facilities, production practices, and products.<sup>4</sup>

Sanitation SOPs (9 CFR 416416.14 Sanitation) Sanitation SOPs are written procedures that an establishment develops and implements to prevent direct contamination or adulteration of product (9 CFR 416.11 General Rules). The establishment is required to maintain these written procedures on file, and they must be available to Food Safety and Inspection Service (FSIS) personnel upon request. The establishment is required to implement the procedures as written in their Sanitation SOPs. The establishment must maintain daily records sufficient to document the implementation and monitoring of the Sanitation SOPs as well as any corrective action taken. When the establishment or FSIS determines that the Sanitation SOPs may have failed to prevent direct contamination or adulteration of product, the establishment must implement corrective actions that include the appropriate disposition of product, restore sanitary conditions, and develop measures to prevent recurrence.

Development of Sanitation SOPs The establishment is required to develop written Sanitation SOPs that clearly describe procedures the establishment will implement to prevent direct contamination or adulteration of product. The Sanitation SOPs cover the entire establishment and all shifts of operation. These written procedures<sup>5</sup> must:

- 1. contain all the procedures the establishment will conduct daily, before and during operation, sufficient to prevent direct contamination or adulteration of product(s) (9 CFR 416.12(a));
- 2. The model presents Sanitation SOPs for Establishment Grounds and Facilities (9 CFR 416.2), Equipment and Utensils (9 CFR 416.3), Sanitary operations (9 CFR 416.4) and Employee hygiene (9 CFR 416.5).

As stated in the HACCP rule, small establishments are defined as all establishments with 10 or more employees but fewer than 500 employees. Very small establishments are defined as all establishments with fewer than 10 employees or annual sales of less than \$2.5 million.

The links to the CFR on pages 1, 2 and 3 take the user to Attachment 2.

To ask questions or find posted Qs and As on these topics, see these external links: askFSIS Q&As and the Small Plant Help Desk.

See public askFSIS Q&As on 9 CFR Part 416.12 requirements. Page 2 of 16", "2 identify the procedures to be conducted prior to operations (pre-operational) and address, at a minimum, the cleaning of food contact surfaces off facilities, equipment, and utensils (9 CFR 416.12(c)); 2 specify the frequency with which each procedure in the Sanitation SOP is to be conducted and identify the establishment employee or position responsible for the implementation and maintenance of the procedures

(9 CFR 416.12(d)); and \u2022 be signed and dated by the individual with overall authority on-site or a higher-level official of the establishment. This signature signifies that the establishment will implement the Sanitation SOPs as written and will maintain the Sanitation SOPs in accordance with the requirements of this part of the regulation (9 CFR 416.12(b)).

**Implementation and Monitoring the Sanitation SOPs** Establishments are required to develop written procedures that are sufficient to prevent direct contamination or adulteration of product. The establishment is also required to implement the procedures in its written Sanitation SOPs (9 CFR 416.13). The pre-operational procedures in the Sanitation SOPs are conducted before the start of operations (9 CFR 416.13(a)). All other written procedures are conducted at the frequencies specified in the Sanitation SOPs (9 CFR 416.13(b)). In addition, establishments are required to monitor daily the implementation of the procedures in the Sanitation SOPs (9 CFR 416.13(c)). If the establishment writes a procedure in its Sanitation SOP, the regulations require that it implement that procedure at the stated frequency and monitor its implementation. **Maintenance of the Sanitation SOPs** Each establishment must meet two obligations to comply with the requirements for Sanitation SOP maintenance (9 CFR 416.14). First, the establishment is required to routinely evaluate the effectiveness of all Sanitation SOPs that have been implemented in their production operations. Second, the establishment is required to revise its Sanitation SOPs as needed to maintain effectiveness and to address any changes that have occurred including changes in facilities, equipment, utensils, operations, or personnel.<sup>6</sup> Establishments are not required to record the methods used to evaluate their Sanitation SOPs and determine their effectiveness. If the establishment determines the Sanitation SOPs are no longer effective and current, they must be modified, signed, and dated. This regulatory requirement encourages establishments to develop a system for the evaluation of their written Sanitation SOPs to prevent direct contamination or adulteration of product. Establishments must identify the employees who are responsible for the implementation and maintenance of their Sanitation SOP procedures (9 CFR 416.12(d)). The establishment is required to identify the frequency with which each procedure is conducted by those employees. The establishment must sign and date the Sanitation SOPs when first created and any time modifications are made (9 CFR 416.12(b)). There are no regulatory requirements for establishment personnel to notify FSIS of any change to their SOPs. <sup>6</sup> See askFSIS Q&As for information on maintenance of Sanitation SOPs. Page 3 of 16", "Corrective Actions The regulations require establishments to take corrective actions when either the establishment or FSIS determines that the Sanitation SOPs failed to prevent direct contamination or adulteration of product (9 CFR 416.15(b)). Regardless of the type or cause of the failure, corrective actions must be taken, including appropriate disposition of product.<sup>7</sup> There are three parts to corrective action, and all three of these requirements must be met and recorded each time product contamination occurs (9 CFR 416.15). One common exception to recording corrective actions individually for each incident of product contamination is when the establishment has an effective product reconditioning program in the operational Sanitation SOP. With such a reconditioning program, they do not need to document each incident of direct contamination of product individually. Inspection personnel will verify that the establishment implements these overarching procedures effectively, including the use of effective<sup>8</sup> procedures to restore products to wholesome, unadulterated conditions. The establishment is not required to notify inspection personnel when product contamination occurs. The establishment is required to

implement corrective actions that will meet the requirements (9 CFR 416.15(b)). Corrective action requirements under these regulations are: \u2022 Appropriate disposition of products that may be contaminated; \u2022 Restoration of sanitary conditions; and \u2022 Prevention of recurrence of direct contamination or adulteration of products. Re-evaluating and modifying the Sanitation SOPs and the specific procedures to which they refer is considered a corrective action. Improvements relating to the implementation of the Sanitation SOPs or the procedures to which they refer are also considered corrective actions. Recordkeeping The regulations require the establishment to maintain daily records (9 CFR 416.16(a)) sufficient to document the implementation and monitoring of the Sanitation SOPs as well as any corrective actions taken.<sup>9</sup> To meet these requirements, the establishment must have records documenting that monitoring has been conducted daily for each of the procedures specified in the Sanitation SOPs. When Sanitation SOP monitoring frequencies are more than once per day, the monitoring activities must be documented at the specified frequencies. The regulations require that the establishment follow the specified monitoring frequency established in the Sanitation SOP. The establishment employee specified in the Sanitation SOPs as being responsible for the implementation and monitoring of the procedures is required to authenticate these records with initials or signature and the date (9 CFR 416.16(a)). Records may be maintained on a computer system provided the establishment implements <sup>7</sup>See askFSIS Q&As for information on Corrective Actions. <sup>8</sup>Establishments must provide supporting information when a prerequisite program becomes part of the HACCP system. See page 16 of the FSIS Compliance Guideline HACCP Systems Validation guide for how to identify support for prerequisite programs. <sup>9</sup> See askFSIS Q&As for information on Recordkeeping. Page 4 of 16", "appropriate controls to ensure the integrity of the electronic data (9 CFR 416.16(b)). Records regarding the implementation of any corrective action must be kept on-site for a period of 48 hours once completed. After 48 hours, the records may be kept off-site but must be made readily available to FSIS within 24 hours of original request. Sanitation SOP records must be maintained for at least 6 months.<sup>10</sup> (9 CFR 416.16(c)). <sup>11</sup> Electronic records may be kept on an in-house computer or remote server for the first 48 hours. The electronic records must be readily available to FSIS during the 48 hour period. Page 5 of 16", "Attachment 1 FSIS developed the Sanitation SOP model for establishments to use as a reference when developing their own Sanitation SOPs. Sanitation SOPs will vary from one establishment to another because each facility will have its own processes that likely differ from that of another. The Sanitation SOP model addresses the sanitation concerns for a fictional company. An establishment must tailor the model to suit the specific circumstances of its own products, production processes and facilities. All elements of the model (e.g., frequencies, monitoring activities, corrective actions, and forms) must be modified (elements added or removed) to reflect the establishment's actual products, production systems and facilities. This Sanitation SOP is for illustrative purposes only. Model \u2013 Sanitation SOP XYZ Meat Packers, Inc. is a red meat processing establishment. This plant receives beef and pork for further processing. This facility cuts, grinds, and packages product. Owner \u2013 Signature: \_\_\_\_\_ Date: \_\_\_\_\_ Plant Manager - Team Captains \u2013 The Team Captains or their designees are responsible for implementing and daily monitoring of Sanitation SOPs and recording the findings and any corrective actions. The Team Captains are responsible for training and assigning specific duties to other employees and monitoring the employees' performance within the Sanitation

SOPs. All records, data, checklists, and other information pertaining to the Sanitation SOPs is maintained on file and made available to inspection personnel.

Pre-operational Sanitation \u2013 Equipment and Facility Cleaning Objective

All equipment is disassembled, cleaned, and sanitized before starting production

Establishment sanitary procedure for cleaning and sanitizing equipment

a. Product debris is removed from all equipment.

b. Equipment is rinsed with water to remove remaining debris.

c. An approved cleaner is applied to equipment and properly cleaned.

d. The equipment is reassembled.

e. Equipment is sanitized with approved sanitizer and rinsed with potable water if appropriate.

Implementing, Monitoring and Recordkeeping Team Captains perform daily organoleptic sanitation examination after preoperational equipment cleaning and just before sanitizing and before operations

11This information is to assist small and very small establishments in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Parts 416.11 \u2013 416.17.

The Sanitation SOP model is for demonstration purposes only.

Establishments are required to develop Sanitation SOPs specific to their facilities, production practices, and products.

Page 6 of 16", "begin.

The results are recorded on the establishment's Pre-operational Sanitation Form.

If found to be acceptable, the appropriate line is checked on the form.

If found unacceptable, actions taken to restore sanitary conditions are documented on the Preoperational Sanitation Form.

Corrective Actions

When the Team Captains determine that the equipment does not pass organoleptic examination, the cleaning procedure and inspections are repeated.

The Team Captains monitor the cleaning of the equipment and retrain employees if necessary.

Corrective actions are recorded on the establishment's Corrective Action Log.

Cleaning of Facilities including floors, walls, and ceilings

Cleaning procedures

1. Debris is swept up and discarded.

2. Facilities are rinsed with potable water.

3. Facilities are cleaned with approved cleaner.

4. Facilities are rinsed with potable water.

Cleaning of floors, ceilings, and walls is done at the end of each production day and when needed to maintain sanitary conditions.

Establishment monitoring

The Team Captain performs daily organoleptic examination before operations begin.

Results are recorded on the establishment's Pre-operational Sanitation Form.

Corrective action

When the Team Captain finds that the facilities do not pass organoleptic examination, the cleaning procedures and inspections are repeated.

The Team Captain examines the cleaning of the facilities and retrains employees as needed.

Corrective actions to prevent direct product contamination or adulteration are recorded on a Corrective Action Log.

Operational Sanitation \u2013 Equipment and Facility Cleaning Objective

Processing is performed under sanitary conditions to prevent direct and cross-contamination of the product

Sanitary procedures for processing

1. Employees clean and sanitize hands, gloves, knives, other hand tools, cutting boards, etc., as necessary during processing to prevent the creation of insanitary conditions and the contamination of products.

2. All equipment tables and other product contact surfaces are cleaned and sanitized throughout the day as needed to maintain sanitary conditions and protect the product.

Page 7 of 16", "3.

Outer garments such as aprons, boots, and gloves are hung in designated areas when employees leave processing areas.

Outer garments are maintained in a clean and sanitary manner and are changed at least daily and more often if necessary.

4. At the midday break: major solids are physically removed from floors, equipment, and food contact surfaces.

Equipment is disassembled as required for adequate cleaning.

All surfaces are rinsed with cold water.

Equipment is sanitized with approved sanitizer and rinsed with potable water as appropriate.

5. At the end of the shift: major solids are physically removed

from floors, equipment, and food contact surfaces. Equipment is disassembled as required for adequate cleaning. All surfaces are rinsed with cold water. 6. Administrative personnel wear smocks and waterproof boots when in processing areas. Smocks are laundered in-house as needed. Maintenance workers wear gray uniforms and waterproof boots. Maintenance uniforms are laundered in-house as needed. 7. Prevention of cross-contamination: clothing and personal belongings are not stored in production areas. Workers do not eat food, chew gum, drink beverages, or use tobacco in production areas. Workers sanitize their boots in boot baths. Waste is removed from processing areas every four hours during production. Coolers are cleaned weekly or more often if needed. Cooler evaporators are cleaned every six months or more often if needed. 8. Allergen control: allergen free products are reprocessed first, followed by products containing allergens. 9. Condensation: drip or condensate does not contaminate food or packaging materials. The finished product cooler is monitored twice a day. Condensation is removed in a sanitary manner. 10. Packaging materials are protected from contamination during storage and use. 11. Cleaning compounds, sanitizers and lubricants used in processing and packaging areas are food-grade. Non-food-grade chemicals and lubricants are stored separately outside processing and packaging areas. 12. Product reconditioning: an employee removes product from the floor in a timely manner, trim contaminants from the product surface area, wash the product at a product wash station, and examines it before returning it to production. This procedure is used for occasional instances of product contamination. 13. Employee health: employees are instructed to report to their supervisor any health condition that might result in food contamination. Monitoring and Recordkeeping The Team Captains are responsible for ensuring that employees' hygiene practices, sanitary handling procedures, and cleaning procedures are maintained. The Team Captains monitor the sanitation procedures during the day. Results are recorded on the establishment's Operational Sanitation Form daily. Page 8 of 16", "Corrective Action The Team Captains identify sanitation problems, stop production if necessary, and notify processing employees to take appropriate action to correct sanitation problems. If necessary, processing employees are retrained, and corrective actions are recorded on a Corrective Action Log. Establishment Grounds and Facilities Grounds and Pest Control Each day, after operations have ended, the Team Captain directs an employee to examine: 1. The area around the building for trash, debris, and garbage. All items found are disposed of in an appropriate waste container; 2. The area around the building for evidence of rodents, flies, and birds (nesting/feeding); 3. The rodent glue traps to ensure they are free of captured rodents and are properly placed and maintained; and, 4. The use and storage of pest control substances to ensure they are used according to manufacturer's instructions and stored securely and away from food production and storage areas. Facilities Each Wednesday, during operations, the Team Captain examines: 5. The structure, rooms, and compartments to verify they are of sound construction and in good repair; 6. The walls, floors, and ceilings to verify they are impervious to moisture and can be cleaned and sanitized; 7. The walls, floors, ceilings, doors, windows, and other outside openings to verify they prevent the entrance of vermin (flies, birds, rats, and mice); 8. The room where edible product is processed, handled, or stored to verify the room and edible products are separate from inedible product storage; 9. The lighting in the product handling and storage rooms, equipment and utensil cleaning area, the hand washing area, the locker room, and the toilet to ensure there is sufficient lighting; 10. The ventilation to verify it controls odors,

vapors, and condensation; 11.The plumbing systemto verify sufficientcity suppliedwateris available where needed in the building, and all floor and sink drains, and the toilet and shower basin remove waste from the building as intended (no backflow or standing water). 12.The supply of running water to verify there is sufficient pressure and temperature in Page 9of 16","the processing room, the cleaning room, hand washing sinks, toilet, and shower. 13. Sec. 416.15 Corrective Actions. (a) Each official establishment shall take appropriate corrective action(s) when either the establishment or FSIS determines that the establishment's Sanitation SOPs or the procedures specified therein, or the implementation or maintenance of the Sanitation SOPs, may have failed to prevent direct contamination or adulteration of product(s). (b) Corrective actions include procedures to ensure appropriate disposition of product(s) that may be contaminated, restore sanitary conditions, and prevent the recurrence of direct contamination or adulteration of product(s), including appropriate reevaluation and modification of the Sanitation SOPs and the procedures specified therein or appropriate improvements in the execution of the Sanitation SOPs or the procedures specified therein. Sec. 416.16 Recordkeeping requirements. (a) Each official establishment shall maintain daily records sufficient to document the implementation and monitoring of the Sanitation SOPs and any corrective actions taken. The establishment employee(s) specified in the Sanitation SOPs as being responsible for the implementation and monitoring of the procedure(s) specified in the Sanitation SOPs shall authenticate these records with his or her initials and the date. (b) Records required by this part may be maintained on computers provided the establishment implements appropriate controls to ensure the integrity of the electronic data. (c) Records required by this part shall be maintained for at least 6 months and made available to FSIS. All such records shall be maintained at the official establishment for 48 hours following completion, after which they may be maintained off-site provided such records can be made available to FSIS within 24 hours of request. Sec. 416.17 Agency verification. FSIS shall verify the adequacy and effectiveness of the Sanitation SOPs and the procedures specified therein by determining that they meet the requirements of this part. Such verification may include: (a) Reviewing the Sanitation SOPs; (b) Reviewing the daily records documenting the implementation of the Sanitation SOPs and the procedures specified therein and any corrective actions taken or required to be taken; (c) Direct observation of the implementation of the Sanitation SOPs and the procedures specified therein and any corrective actions taken or required to be taken; and (d) Direct observation or testing to assess the sanitary conditions in the establishment. Page 16 of 16"]}, {"file\_name": "FSIS\_GD\_2020\_0010", "title": "HACCP Model for Raw Non-Intact Fresh Ground Pork Sausage Patties", "num": "FSIS-GD-2020-0010", "id": "65a55d0ec064091577c9c157bd9f4c9dafb8ce8e5e1a3b971dafe61684756bbe", "cor

The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to address safety hazards reasonably likely to occur in their production process. Therefore, this HACCP model's focus, and the focus of the other HACCP models, is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic model for each food processing category defined in the regulation (9 CFR 417.2(b)(1)). The guidebook and the generic models have been updated since their initial publication to be consistent with current science and policy. FSIS recommends you use of the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used as is. FSIS recommends that establishments tailor the model(s) to fit the establishment's operation. The model's critical control points (CCPs) do not necessarily apply to all operations or products in the product category. Products or operations may require fewer or more CCPs depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The food safety critical limits selected must come from scientific documents or other reliable sources to meet regulatory validation requirements. Each model includes references for guidance on the selection of critical limits. To select the model that will be most useful for the products produced, consider the production activity occurring (slaughter, cutting, grinding, smoking, cooking, etc.), the product (beef, pork, chicken, etc.), and the food safety characteristics of the final product produced (intact or non-intact, raw or ready-to-eat, requires refrigeration or is shelf-stable, etc.). Examine the list of processing categories (9 CFR 417.2(b)(1)) and group similar products according to the categories. Many similar products may be grouped under the same category and HACCP plan. Selection of the processing categories reveal which of the generic models might be useful. Selecting the most appropriate model to work from will save the establishment time and personnel resources. Deciding on a generic model is an important achievement for your establishment. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis are HACCP records (CFR 417.5(a)). The selection of processing categories and HACCP models are preliminary steps to completing a hazard analysis. The documents produced during the selection process are HACCP records. Ensure you maintain the documents produced while developing a HACCP plan. For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage. Page 1 of 12", "EXAMPLE PRODUCT DESCRIPTION1 Process \ Product Name: Fresh Ground Pork Sausage Patties Process \ Product Name Non-intact pork product (sausage

Establishments determine which steps are included in their process. The steps must represent all relevant hazards in the hazard analysis. 6 The Returned Product step(10) is shown as not connected to another process step. Returned product may re-enter the production system at different process steps depending on

condition or problem. Returned product may be relabeled, reground, discarded, tempered, etc.

Page 4 of 12", "EXAMPLE HAZARD ANALYSIS7 Fresh Ground Pork Sausage Patties Column 1

Column 2 Column 3 Column 4 Column 5 Column 6 Ingredient \ Process Step Potential Hazards (introduced or controlled) at this Step8 Is the Potential Food Safety Hazard Reasonably Likely to Occur (NRLTO)? (Yes or No)9 Justification \ Basis for Decision in Column 310 If yes in Column 3 (hazard RLTO), What Control Measures Can Be Applied to Prevent, Eliminate, or Reduce the Hazard to Acceptable Levels11 Is this Step a Critical Control Point (CCP)?12 This is an example hazard analysis. Establishments\u2019 hazard analyses for the same product may be different. Establishments determine which hazards are applicable to their process. 8 Hazards are grouped into three categories: Biological(B), Chemical (C), and Physical(P). Biological hazards are living organisms. Chemical hazards maybe naturally occurring in foods, used, or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification. 9 Place the justification for your decision in column 4. Include control measures in column 4 for hazards not reasonably likely to occur and place them in column 5 for hazards reasonably likely to occur. If a hazard is reasonable likely to occur, then a CCP must be addressed at this step or a later step. See FSIS Meat and Poultry Hazards and Controls Guide for a list of frequently used controls. 10 Scientific references are important in making decisions and providing justifications. When scientific references are used for decisions, the referenced article must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS program, then scientific or technical support is needed, and these non-FSIS supporting documents must be kept for the life of the HACCP plan.

11 Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5).

12 To determine the best CCP to control, reduce, or eliminate a hazard, see FSIS Guidebook for the Preparation of HACCP Plans.

Page 5 of 12", "Step Hazard RLTO Justification \ Basis Controls CCP 1. Receiving Fresh B:

Pathogens: No Pathogens known to be present and likely to or Frozen Raw Pork Salmonella outgrowth Trichinella spiralis13 No cause illness if not controlled. Pork trimmings are either sourced from in-house production or purchased. Pork trimmings may be processed fresh or placed in frozen storage for later use. Written Temperature Control SOP for maintaining product temperatures to prevent outgrowth of micro-organisms (The Significance of time-temperature to growth of foodborne pathogens during refrigeration at 40-50\u00b0F (Tompkin, R.B. 1996)). Letter of Guarantee is on file from the originating slaughter facility of

purchased product. The blanket LOG is updated annually. Not ready-to-eat pork products, including all forms of fresh pork, do not need to be treated to destroy *Trichinella* because they are customarily wellcooked in the home or elsewhere before being served to the consumer. Product label principle display panel includes the statement \u201cCook to an internal temperature of 160 degrees Fahrenheit as measured by a food thermometer\u201d to clearly indicate the products require additional treatment by the consumer. C: Allergens No Letter of Guarantee is on file from the originating slaughter facility of purchased product. The blanket LOG is updated annually. 13 This HACCP model uses option 3 Label NRTE pork products, including all forms of fresh pork to clearly indicate the products require additional treatment by the consumer described in the FSIS Compliance Guideline for the Prevention and Control of *Trichinella* and Other Parasitic Hazards in Pork and Products Containing Pork. Page 6of 12", "Step Hazard RLTO Justification \ Basis Controls CCP P: Foreign material No Written Foreign Material SOP14 for visual inspection of product in containers at receiving. Records generated from the Foreign Material SOP demonstrate no incidents of foreign materials detected in products received. 1a. An establishment can determine what steps are included in the overall process as long as all of the hazards are considered in the hazard analysis. 7This model demonstrates two approaches to carcass preparation, either all carcasses are skinned (proceed from step 2 directly to step 4b), or carcasses are scalded (step 2 through steps 3, 4, and 4a). 8 The Returned Productstep (15)is shown as notconnectedto another process step. Returned product may re-enter the production system at different process stepsdepending on conditionor problem. Returned product may be relabeled, reprocessed, discarded, etc. Page 4of 17", "EXAMPLE MARKET HOG SLAUGHTER HAZARD ANALYSIS9 Column 1 Column 2 Column 3 Column 4 Column 5 Column 6 Ingredient, Process Step Potential Hazards (Introduced or Controlled) at this Step10 Is the Potential Food Safety Hazard Reasonably Likely to Occur (RLTO)? (Yes or No)11 Justification \ Basis for Decision12 If yes in Column 3 (hazard RLTO), What Control Measures Can Be Applied to Prevent, Eliminate, or Reduce the Hazard to Acceptable Levels13 Is this Step a Critical Control Point (CCP)?14 9 See FSIS Compliance Guideline for Controlling Salmonella in Market Hogs, FSISCompliance Guideline for the Prevention and Controlof Trichinella and Other Parasitic Hazards in Pork and Products Containing Pork, and FSISCompliance Guide: Modernization of Swine Inspection System for suggested slaughter best practices and a list of scientific and technical references. 10 Hazards are grouped into threecategories:Biological(B), Chemical (C), and Physical(P). Biological hazardsarelivingorganisms. Chemical hazardsmaybe naturallyoccurringin foods, used, or added duringthe processingoffoods, or administered to live animals. Physical hazards areacomponent ofafood that is unexpected, such asplastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification. 11Place thejustification for your decision in column 4. Include control measures in column 4 forhazards not reasonably likely to occurand place them in column 5 forhazards reasonably likely to occur. If a hazard is reasonable likely to occur,then a CCP must beaddressed at this step or a later step. See FSISMeat and Poultry Hazards and Controls Guide for a list of frequently used controls. 12Scientificreferences are important in making decisions, providing justifications, and validating the HACCPsystem. When scientific references are used for decisions, the referencedarticle must be part ofthe HACCP records. If the scientificjustification isfromFSIS, then list the document name. If justificationis not from an FSISprogram, then HACCP system design must be supported by documentary evidence \u2013that is,documents depictingthe theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan. 13Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishmentis required to maintain records

associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5). 14 To determine whether a CCP is necessary, see Guidebook for the Preparation of HACCP Plans for decision tree to evaluate the areas of control (column 5) to determine the best CCP to control, reduce, or eliminate a hazard. Page 5 of 17", "Step Hazard RLTO Justification \ Basis Controls CCP 1. Live Hog Receiving B: Pathogens, Salmonella Trichinella 15 Yes No Live hogs may have pathogens on hair, skin, feet, and in the digestive tract. APHIS 16 validated Trichinella pre-harvest safety program. Therefore, the hazard is not reasonable likely to occur and treatment of such products for the destruction of Trichinæ is not necessary. Controlled at Subsequent CCP in process: CCP 1: Zero Tolerance Examination, CCP 2: Organic Acid Spray. Maintain adequate sanitation in holding pens, Good Manufacturing Practices. Documented pre-harvest farm management measures to reduce Salmonella. Transportation controls to reduce stress and fecal shedding, as well as crosscontamination. No C: Drug No Low risk per USDA Residue Monitoring residues Program, Compliance Guide for Residue Prevention. Residue certifications for live animals. Written Drug Residue Control SOP (Standard Operating Procedure). P: Foreign material, metal No Recorded historical data from written Foreign Material SOP 17 indicates low 15 See , FSIS Compliance Guideline for Controlling Salmonella in Market Hogs for guidance on controlling Salmonella and FSIS Compliance Guideline for the Prevention and Control of Trichinella and Other Parasitic Hazards in Pork and Products Containing Pork for options used to prevent the control of Trichinella in pork and pork products. 16 USDA Animal and Plant Health Inspection Service 17 Example: This Foreign Material SOP (prerequisite program) should have details on how this procedure is preventing the hazard from occurring (metal prevention controls) as well as the on-going verification procedures. These controls should be evident within the written document upon review. The Foreign Material SOP and plant data related to validation and on-going verification activities then become part of recordkeeping and historic data. Page 6 of 17", "Step Hazard RLTO Justification \ Basis Controls CCP (needles, likelihood at this establishment and from wire) suppliers. 18 Written Visual Ante-mortem Examination of Swine SOP for observation of live hogs in holding pens, carcasses during dressing, and parts, viscera, and equipment during processing make this hazard not reasonably likely to occur. 1a. Slaughter.pdf", "type": "pdf", "n\_pages": 23, "word\_count": 5948, "text\_by\_page": ["A Generic HACCP Model for New Poultry Inspection System (NPIS) The United States Department of Agriculture (USDA) published the Pathogen Reduction\Hazard Analysis Critical Control Point (HACCP) Systems Final Rule in July 1996. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to address safety hazards reasonably likely to occur in their production process. Therefore, this HACCP model\u2019s focus, and the focus of the other HACCP models, is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic modelfor each food processing category defined inregulation (9 CFR 417.2(b)(1)). The guidebook and the generic models have been updated since their initial publication to be consistent with current science and policy. FSIS recommends you use of the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as usefulexamples ofhow to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used \u201cas is\u201d. FSIS recommends that establishments tailor the model(s) to fit the establishment\u2019s operation. The model\u2019s critical control points (CCPs) do not necessarily apply to all operations or products in the product category. Products or operations may require fewer or more CCPs depending on the operation. The flowdiagram demonstrates a general production process and should be modified toreflecttheprocesses used at theestablishment. The food safety criticallimits selected must come from scientific documents or other reliable sourcesto meet regulatory validation requirements. Each modelincludes references for guidance on the selection of critical limits. To select the model that will be most useful for the products produced, consider the production activity occurring (slaughter, cutting, grinding, smoking, cooking, etc.), the product (beef, pork, chicken, etc.), and the food safety characteristics of the final product produced (intact or nonintact, raw or ready-to-eat, requires refrigeration or is shelf-stable, etc.). Examine the list of processing categories (9 CFR 417.2(b)(1)) and group similar products according to the categories. Many similar products may be grouped under the same category and HACCP plan. Selection of the processing categories reveal which of the generic models might be useful. Selecting the most appropriate model to work from will save the establishment time and personnel resources. Deciding on a generic model is an important achievement for your establishment. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis are HACCP records ((CFR 417.5(a)). The selection of processing categories and HACCP models are preliminary steps to completing a hazard analysis. The documents produced during the selection process are HACCP records. Ensure you maintain the documents produced while documenting a HACCP plan For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage. Page 1of 23", "EXAMPLE PRODUCT DESCRIPTION1 Process \ Product Name: New Poultry Inspection System (NPIS) Poultry Slaughter \ Whole Carcasses, Parts, Other Intact Poultry Products Process \ product type name Young Ready-to-Cook chicken, other types of whole dressed poultry carcasses (turkeys, ducks, geese), single ingredient intact poultry products, such as

parts, giblets2, paws, and turkey fries Important product characteristics (Aw, pH, preservatives, etc.) Not Applicable How it is to be used For further processing at this facility or another establishment or intended for cooking by end consumer Packaging (durability and storage conditions) Vacuum packaged, tray packs, giblets in plastic sealed containers, bulk pack boxes with liners. 6. Establishment sorting of carcasses (and associated viscera) and disposal of carcasses exhibiting septicemic and toxemic conditions, routing of carcasses with digestive tract contaminants to reprocessing and routing carcasses with localized pathology (e.g., airsacculitis) to offline salvage 10. Crop, Lung, and Kidney Removal 9. Offline Reprocessing and Salvage CCP 2 11. Inside and Outside Carcass Wash 13. Online Reprocessing (optional) 14. Monitoring Carcasses for Fecal Contamination and septicemic and toxemic conditions CCP 1 15. Pre-chilling antimicrobial application CCP 3 19. Shipping 18. Cold Storage 8. This is an example flow diagram. Establishments \u2019 flow diagrams for the same product may be different. Establishments determine which steps are included in their process. The steps must represent all relevant hazards in the hazard analysis. Step 6, Establishment Sorting of Carcasses (and associated viscera), is represented in this model by a single box in the flow chart. Establishments use different approaches and a variety of processing techniques leading up to their sorting activity (9 CFR 381.76 (b)(6)(ii)(A)). Therefore, step 6 may represent a number of different carcass preparation practices.

Page 4 of 23, "EXAMPLE POULTRY SLAUGHTER HAZARD ANALYSIS"

Column 1 Column 2 Column 3 Column 4 Column 5 Column 6 Ingredient \ Process Step

Potential Hazards (introduced or controlled) at this step 10 Is the Potential Food Safety Hazard Reasonably Likely to Occur (RLTO)? (Yes or No) 11 Justification \ Basis for Decision 12 If yes in Column 3 (hazard RLTO), What Control Measures Can Be Applied to Prevent, Eliminate, or Reduce the Hazard to Acceptable Levels 13 Is this Step a Critical Control Point (CCP)? 14 1. Receive Live Birds B: Pathogens Salmonella, Campylobacter Yes Live birds may have pathogens on feathers, skin, feet, and in the digestive tract. The hazard is controlled at later steps with visual examination for contaminants, antimicrobial application and chilling (CCPs 1 and 2, CCP 3, CCP 4). No 10 Refer to FSIS Meat and Poultry Hazards and Controls Guide and DRAFT FSIS Compliance Guideline For Controlling Salmonella and Campylobacter in Raw Poultry for suggested practices and controls. 10 Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P). Biological hazards are living organisms. Chemical hazards maybe naturally occurring in foods, used, or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification. 12 Place the justification for your decision in column 4. Include control measures in column 4 for hazards not reasonably likely to occur and place them in column 5 for hazards reasonably likely to occur. If a hazard is reasonable likely to occur, then a CCP must be addressed at this step or a later step. See FSIS Meat and Poultry Hazards and Controls Guide for a list of frequently used controls. 13 Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced article must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS program, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan. 14 Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to

maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5).

15 To develop an effective CCP, see the FSIS Guidebook for the Preparation of HACCP Plans for a CCP decision tree and guidance on how to control, reduce, or eliminate a hazard. Page 5 of 23", "Step Hazard RLTO Justification \ Basis Controls CCP Truck Sanitation SOP for cage cleaning between flocks. Pre-Harvest Controls. Feed Withdrawal Standard Operating Procedure (SOP). C: Drug residues No Low risk per FSIS Compliance Guide for Residue Prevention.15 Growers required to follow best preharvest practices, which include appropriate withdrawal requirements when antibiotics are prescribed. P: Foreign objects in the gizzards of live birds No Establishment historical data16 (that is, giblet quality monitoring) demonstrates low risk of foreign objects in gizzards after processing. Foreign Material SOP.17 Gizzard quality checks after chilling, which include monitoring for foreign objects, such as wire. 1a. Receive Non-meat Items (for example, B: None C: Inappropriate chemical or No Establishment historical data shows low risk of receipt of inappropriate 16 If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS program, then scientific or technical support is needed, and these non-FSIS supporting documents must be kept for the life of the HACCP plan. 17 Note: this historical data must be supported with evidence from the establishment through the establishment's history or validation data with reference to the actual SOP or prerequisite program. When historical data is not available (for example, a HACCP plan for a new process or product), then system design must be supported by other documentary evidence. Such as the FSIS Meat and Poultry Hazards and Controls Guide which states "monitor giblets for foreign materials" is a frequently used control for foreign material hazards in poultry slaughter.. 17 This Foreign Material SOP (prerequisite program) should have details on how this procedure is preventing the hazard from occurring (such as metal prevention controls) as well as the on-going verification procedures. These controls should be evident within the written document upon review. The Foreign Material SOP and plant data related to on-going verification activities then become part of recordkeeping and historic data.

Page 6 of 23", "Step Hazard RLTO Justification \ Basis Controls CCP Antimicrobials, Packaging Materials) concentration received chemicals and inappropriate chemical compounds Letters of Guarantee from suppliers. Identify and list all approved chemicals used in the operations. Check each chemical at receiving to assure that it is on the list at the correct concentration and is appropriately labeled. Safety Data Sheets (SDS) P: None 2. Unloading, Stunning, Bleeding B: Pathogens Salmonella, Campylobacter Yes Live birds may have pathogens on feathers, skin, feet, and in the digestive tract. The hazard is controlled at later steps with visual examination for contaminants, antimicrobial application and chilling (CCPs 1 and 2, CCP 3, CCP 4). Proper application of stunning methods and maintenance of stunning equipment to reduce involuntary

voiding of feces. Employee hygienic practices. Air flow directed away from further processes. No C: None P: None 3. Scalding, B: Pathogens Yes Scald water and picking machinery can The presence of pathogens is controlled No Picking, Head and Feet Removal Salmonella, Campylobacter increase pathogen cross-contamination. Pathogens can contaminate muscles of carcasses that are mutilated during picking. at later steps with antimicrobial application and chilling (CCP 3, CCP 4). Scalder operational procedures for freshwater intake and overflow, agitation of scald water. Page 7of 23","Step Hazard RLTO Justification \ Basis Controls CCP Multi-stage scald tanks with counter current water flow to result in lower bacterial levels where the birds exit the scalder compared to where the birds enter the scalder. Optional use of brushes to remove dirt and debris from birds prior to scalding. Water pH maintained either above or below optimum pH for Salmonella and Campylobacter growth. Antimicrobials, acidifiers and anti-foam chemicals applied in the scald water as part of a multi-hurdle approach to reduce enteric pathogens.<sup>18</sup> Prerequisite program to monitor antimicrobial and any other chemical concentrations. Trim mutilated portions from carcasses later in the process. Written Sanitation SOP for equipment cleaning and sanitation to prevent product contamination. C: Antimicrobial, No Establishment historical data shows defoamer, or pH low risk of chemical contamination by modifier not use of defoamers and pH boosters in appropriately scalders. mixed to meet 18 Provide reference for scientific support and validation for effective concentrations and support for critical operationalparameters that reduce biological hazards. FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat,Poultry and Egg Products contains the list of substances that maybe used in the production of meat and poultry products. The list contains the allowable amounts and the intended use of the approved antimicrobials. The list (Directive 7120.1) can be used as supporting documentation for chemical hazard controls(safety and suitability). Directive 7120.1 cannot be used as support for the control of biological hazards because the antimicrobial concentration needed to control bacteria is different fromthe concentrations required for safety and suitability. Page 8of 23","Step Hazard RLTO Justification \ Basis Controls CCP Generally Recognized as Safe (GRAS) parameters Written chemical mixing procedures and documented verification procedures to ensure that critical operating parameters are maintained. Page 21 of 23", "Critical Control Point (CCP) Significant Hazard(s) Critical Limits for Each Control Measure Monitoring Procedures Corrective Action Verification Records What How Frequency Who CCP 3 Prechilling antimicrobial applications 25 Pathogens: Salmonella, Campylobacter 600-700 ppm organic acid solution 26 Antimicrobial Solution concentration and method of application to carcasses, salvaged parts, reprocessed carcass parts, giblets, necks and feet. Measure the concentration of the antimicrobial solution at the point of application. (for example, 600-700 ppm organic acid solution) using titration kit supplied by chemical manufacturer. Twice per shift Designated employees If antimicrobial concentration wash exceeds critical limits, then all product from the last acceptable check will be retained and evaluated for further disposition. If a deviation from the critical limit occurs, the production supervisor will, per 9 CFR 417.3(a): 1. Hold all product produced after the last acceptable check until appropriate disposition taken (no product injurious to health will enter commerce); 2. Determine and eliminate the cause of the deviation; 3. Bring the CCP under control; 4. Take measures to prevent recurrence. Randomly, once per day, an employee observes the measurement of the concentration of the antimicrobial solution at the point of application. Records Reviewed once a week (9 CFR 417.4(a)(2)(iii)). Organic Acid Spray Concentration Form. Corrective Action Log 26 If an establishment implements a process consistent with the process specifications described in the scientific support, and the scientific support contains microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, the in-plant validation data collected during the 90 day initial validation period will consist of data on quantifiable characteristics of the critical operational parameters, such as pressure, temperature, and concentration. However, if an establishment implements different critical operational parameters in the process from the scientific support, or the scientific support identified does not contain microbiological data, then the establishment should collect in-plant

data demonstrating the critical operational parameters that it has implemented can all be met AND should collect in-plant microbiological validation data or identify scientific support with microbiological data that demonstrates the effectiveness of those implemented critical operational parameter (FSIS Compliance Guideline HACCP Systems Validation, page 27). 27 Scientific or technical support is required to validate the critical limits and critical parameters (for example, time of exposure) of the organic acid spray. They are part of the hazard analysis and need to be maintained for the life of the HACCP plan (see FSIS Compliance Guideline HACCP Systems Validation); FSIS Directive 7120.1 Safe and Suitable Ingredients Used in the Production of Meat, Poultry, and Egg Products contains approved substances for use in poultry; however, each establishment must validate their own process. Page 22 of 23", "- Critical Critical Limits for Monitoring Procedures Corrective Action Verification Records Control Point (CCP) Significant Hazard(s) Each Control Measure What How Frequency Who CCP 4 Chilling of all Products Pathogen Outgrowth: *Salmonella*, *Campylobacter* Carcass temperature of 45 degrees or less within 6 hours. Parts, giblets, feet, and necks chilled to 44 degrees or less within 4 hours from the time they are removed from the inedible viscera. Carcass internal temperature. Parts, Giblets, Feet, and Necks internal temperature. Handheld properly calibrated thermometer inserted into the thickest portion of the breast muscle of the carcass, or thickest portion of the part, gullet, neck or foot. Check 10 carcasses for each production hour at random times selected during the production hour. Check up to 10 parts, giblets, necks or feet each production hour at random times selected during the production hour. If 10 units are not available at this time all units are checked. Designated employees If a deviation from the critical limit occurs, the production supervisor will, per 9 CFR 417.3(a): 1. Hold all product produced after the last acceptable check until appropriate disposition taken (no product injurious to health will enter commerce); 2. Determine and eliminate the cause of the deviation; 3. Bring the CCP under control; 4. Take measures Observe the person who monitors the CCP once each day the establishment slaughters. Once per week, supervisor will calibrate thermometer per manufacturer's procedures. Records reviewed once a week (9 CFR 417.4(a)(2)(iii)).

Page 23 of 23"]}, {"file\_name": "FSIS\_GD\_2020\_0013", "title": "HACCP Model for Poultry Slaughter", "num": "FSIS-GD-2020-0013", "id": "0af929f11f36f78b569e2a4259cb79669aec2f0d983fd806604a8bc6176780d7", "corp\_us": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/media\_file/2021-03/HACCP-Model-for-Poultry-Slaughter.pdf", "type": "pdf", "n\_pages": 19, "word\_count": 5610, "text\_by\_page": ["Page 1 of 19 A Generic HACCP Model for Poultry Slaughter The United States Department of Agriculture (USDA) published the Pathogen Reduction/Hazard Analysis Critical Control Point (HACCP) Systems Final Rule in July 1996. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to address safety hazards reasonably likely to occur in their production process. Therefore, this HACCP model's focus, and the focus of the other HACCP models, is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic model for each food processing category defined in regulation 9 CFR 417.2(b)(1). The"]}

guidebook and the generic models have been updated since their initial publication to be consistent with current science and policy. FSIS recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used as is. FSIS recommends that establishments tailor the model(s) to fit the establishment's operation. The model's critical control points (CCPs) do not necessarily apply to all operations or products in the product category. Products or operations may require fewer or more CCPs depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The food safety critical limits selected must come from scientific documents or other reliable sources to meet regulatory validation requirements. Each model includes references for guidance on the selection of critical limits. FSIS published two poultry slaughter HACCP models. This model can be used with the Streamlined Inspection System (SIS), New Evisceration Line Speed (NELS), New Turkey Inspection System (NTIS) and Traditional poultry slaughter inspection systems. The other published model can be used with the New Poultry Inspection System (NPIS). The defining difference between this model and the NPIS model is the additional NPIS responsibility of sorting and disposing of carcasses and viscera exhibiting septicemic and toxemic conditions. Many Small and Very Small poultry slaughter establishments operate under Traditional Inspection and this is the model best suited for those operations. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis, are HACCP records ((CFR 417.5(a)). The selection of a poultry slaughter HACCP model is a preliminary step to completing a hazard analysis. The documents produced during the selection process are HACCP records. Ensure you maintain the documents produced while developing a HACCP plan. For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage.", "Page 2 of 19 EXAMPLE PRODUCT DESCRIPTION1 Process \ Product Name: Poultry Slaughter2 Whole Carcasses, Parts, Other Intact Poultry Products Process \ product type name Young Ready-to-Cook chicken, other types of whole dressed poultry carcasses (turkeys, ducks, geese), single ingredient intact poultry products, such as parts, giblets, paws, and turkey fries Important product characteristics (Aw, pH, preservatives, etc.) Not Applicable How it is to be used For further processing at this facility or another establishment or Intended for cooking by end consumer Packaging (durability and storage conditions) Vacuum packaged, tray packs, giblets in plastic sealed containers, bulk pack boxes with liners. Returned Product", "Page 5 of 19 EXAMPLE POULTRY SLAUGHTER HAZARD ANALYSIS<sup>9</sup> 9 Refer to FSIS Meat and Poultry Hazards and Controls Guide and DRAFT FSIS Compliance Guideline For Controlling Salmonella and Campylobacter in Raw Poultry for suggested practices and controls. 10 Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P). Biological hazards are living

organisms. Chemical hazards may be naturally occurring in foods, used, or added during the processing of foods, or administered to live animals. Physical hazards are a component in a food product that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification.

11 Place the justification for your decision in column 4. Include control measures in column 4 for hazards not reasonably likely to occur and place them in column 5 for hazards reasonably likely to occur. If a hazard is reasonable likely to occur, then a CCP must be addressed at this step or a later step. See FSIS Meat and Poultry Hazards and Controls Guide for a list of frequently used controls.

12 Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced article must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS program, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peerreviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan.

13 Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5).

14 To develop an effective CCP, see the FSIS Guidebook for the Development of HACCP Plans for a CCP decision tree and guidance on how to control, reduce, or eliminate a hazard.

Column 1	Column 2	Column 3	Column 4	Column 5	Column 6

Justification	\ Basis	Controls CCP	Page 6 of 19	15 If the scientific justification is from FSIS, then list the document name.	

If justification is not from an FSIS program, then scientific or technical support is needed, and these nonFSIS supporting documents must be kept for the life of the HACCP plan

16 NOTE: This \u201chistoric data\u201d must be supported with evidence from the establishment through the establishment\u2019s history or validation data with reference to the SOP or prerequisite program. When historical data is not available (for example, a HACCP plan for a new process or product), then system design must be supported by other documentary evidence. Such as the FSIS Meat and Poultry Hazards and Controls Guide which

states \u201cMonitor giblets for foreign materials\u201d and \u201cMetal detection\u201d as frequently used controls for foreign material hazards in poultry slaughter.<sup>17</sup> This Foreign Material SOP (prerequisite program) should have details on how this procedure is preventing the hazard from occurring (such as metal prevention controls) as well as the on-going verification procedures. These controls should be evident within the written document upon review. The Foreign Material SOP and plant data related to on-going verification activities then become part of recordkeeping and historic data.

1. Receive Live Birds B: Pathogens Salmonella, Campylobacter Yes Live birds may have pathogens on feathers, skin, feet, and in the digestive tract. The hazard is controlled through subsequent visual examination, antimicrobial application and chilling (CCP 1, CCP 2, CCP 3). Truck Sanitation Standard Operating Procedure (SOP) for cage cleaning between flocks. Pre-Harvest Controls Feed Withdrawal SOP. No C: Drug residues No Low risk per USDA, Compliance Guide for Residue Prevention.<sup>15</sup> Growers required to follow best preharvest practices, which include appropriate withdrawal requirements when antibiotics are prescribed. P: Foreign objects in the gizzards of live birds No Establishment historical data<sup>16</sup> (that is, gilet quality monitoring) demonstrates low risk of foreign objects in gizzards after processing. Gizzard quality checks after chilling, which include monitoring for foreign objects, such as wire. Foreign Material SOP<sup>17</sup>, "Step Hazard RLTO Justification \ Basis Controls CCP Page 7 of 19<sup>18</sup> Provide reference for scientific support and validation for effective concentrations and support for critical operational parameters that reduce biological hazards.

FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat, Poultry and Egg Products contains the list of substances that may be used in the production of meat and poultry products. The list contains the allowable amounts and the intended use of the approved antimicrobials. The list (Directive 7120.1) can be used as supporting documentation for chemical hazard controls (safety and suitability). Directive 7120.1 cannot be used as support for the control of biological hazards because the antimicrobial concentration needed to control bacteria is different from the concentrations required for safety and suitability.

1a. Receive and Store Non-meat Items (e.g., Antimicrobials, Packaging Materials) B: Contamination with Pathogens No Proper storage of non-meat ingredients under temperature control if needed. Procedure to protect non-meat ingredients from pests and environmental contamination. C: Inappropriate chemical or concentration received<sup>18</sup> No Establishment historical data shows low risk of receipt of inappropriate chemicals and inappropriate chemical compounds. Letters of Guarantee from suppliers. Identify and list all approved chemicals used in the operations. Check each chemical at receiving to assure that it is on the list at the correct concentration and is appropriately labeled. Safety Data Sheets (SDS) P: Foreign Materials No Visual inspection for foreign material. Protect packaging materials from environment.

2. Unloading, Stunning, Bleeding B: Pathogens Salmonella, Campylobacter Yes Live birds may have pathogens on feathers, skin, feet, and in the digestive tract. The hazard is controlled through subsequent visual examination, antimicrobial application and chilling (CCP 1, CCP 2, CCP 3). Proper application of stunning methods and maintenance of stunning No", "Step Hazard RLTO Justification \ Basis Controls CCP Page 8 of 19 equipment to reduce involuntary voiding of feces during stunning. Employee hygienic practices. C: None P: None

3. Scalding, Picking, Head and Feet Removal B: Pathogens Salmonella, Campylobacter Yes Scald water and picking machinery can increase pathogen cross-contamination. Pathogens can contaminate muscles of carcasses that are mutilated during picking. The hazard is controlled through subsequent visual

examination, antimicrobial application and chilling (CCP 1, CCP 2, CCP 3). Scald operational procedures for freshwater intake and overflow, agitation of scald water. Scald water is not reused as scalding water or wash water. Optional use of brushes to remove dirt and debris from birds prior to scalding. Water pH maintained either above or below optimum pH for *Salmonella* and *Campylobacter* growth. Antimicrobials, acidifiers and anti-foam chemicals applied in the scald water as part of a multi-hurdle approach to reduce pathogen levels. Prerequisite program to monitor antimicrobial and any other chemical concentrations Trim mutilated portions from carcasses later in the process. Written Sanitation SOP for equipment cleaning and sanitation to prevent product contamination. No", "Step Hazard RLTO Justification \ Basis Controls CCP Page 9 of 19 19 DRAFT FSIS Compliance Guideline for Controlling *Salmonella* and *Campylobacter* in Raw Poultry provides guidance on how to control pathogens throughout the slaughter operation. 20 The required written procedures to prevent contamination may also include: an equipment maintenance program to ensure machinery functions as intended to prevent contamination with digestive tract contents throughout the evisceration process; programs to ensure the proper application of antimicrobials (for example, antimicrobial concentration and method of application); employee hygienic practices and an operational sanitation SOP. C: Antimicrobial, defoamer, or pH modifier not appropriately mixed to meet Generally Recognized as Safe (GRAS) parameters No Establishment historical data shows low risk of chemical contamination by use of defoamers and pH boosters in scalders. Written chemical mixing procedures and documented verification procedures to ensure that critical operating parameters are maintained. Chemicals are properly used to meet the chemical manufacturer\u2019s recommendations and GRAS parameters. P: None 4. Evisceration19, including neck removal, venting, opening, drawing viscera from carcass B: Pathogens *Salmonella*, *Campylobacter* Yes Pathogens introduced on live birds present on carcass skin and in the digestive tracts. The hazard is controlled through subsequent visual examination, antimicrobial application and chilling (CCP 1, CCP 2, CCP 3). Written Sanitary Dressing Procedures to prevent contamination of carcasses and parts by enteric pathogens and fecal contamination throughout the slaughter and dressing operations incorporated as a prerequisite program to meet 9 CFR 381.65(g) requirements.20 These requirements include sampling and analysis for microbial organisms to monitor and maintain process control. No C: None", "Step Hazard RLTO Justification \ Basis Controls CCP Page 10 of 19 21 The FSIS Compliance Guide: Modernization of Poultry Slaughter Inspection: Chilling Requirements describes how establishments can meet the poultry chilling regulatory requirements. P: Foreign Material No Foreign materials could be introduced from broken machinery parts, broken shackles, and insanitary overhead structures. Equipment and evisceration line maintenance to prevent metal or plastic contamination. Routine cleaning of shackle rails and overhead structures. Foreign Material SOP. 5. Harvest of Giblets, Necks and Feet B: Pathogens: *Salmonella*, *Campylobacter* Yes Delayed separation from inedible items may result in pathogen outgrowth. The hazard is controlled through subsequent visual examination, antimicrobial application and chilling procedures (CCP 1, CCP 2, CCP 3). Chilling time and temperature critical limits monitored through CCP 3 to ensure that giblets, necks, and feet temperatures are promptly reduced to temperatures that prevent pathogen outgrowth.21 Antimicrobial added to immersion chiller media or applied through a spray or dip. Written Sanitary Dressing Procedures to prevent contamination of carcasses and parts by enteric pathogens and fecal contamination throughout

the slaughter and dressing operations incorporated as a prerequisite program to meet 9 CFR 381.65(g) requirements. No", "Step Hazard RLTO Justification \ Basis Controls CCP Page 11 of 19 22 For an example hazard analysis for on-line reprocessing see step 13 of the HACCP Model for New Poultry Inspection System (NPIS) Poultry Slaughter. C: Inappropriate concentration of antimicrobial No Establishment historical data shows low risk of inappropriate chemical application. Written chemical mixing procedures and documented verification procedures to ensure that critical operating parameters are maintained. Chemicals are properly used to meet the chemical manufacturer\u2019s recommendations and GRAS parameters. P: Foreign material (rocks, wires, other building materials etc.) from birds pecking at litter during live production No Establishment historical data (giblet quality monitoring) demonstrates low risk of foreign objects in gizzards after processing. Foreign Material SOP. Giblet quality checks after chilling, which include monitoring for foreign objects, such as wire, that may be lodged in gizzards. 6. Offline Reprocessing and Salvage22 B: Pathogens Salmonella, Campylobacter Yes Carcasses accidentally contaminated with digestive tract contents (feces and ingesta) at higher risk for pathogen contamination. Disease conditions may contain pathogens. Digestive tract contaminants are addressed with CCP 1: Monitoring Carcasses, Parts and GIBLETS for Fecal Contamination. The presence of pathogens is addressed with CCP 2 Pre-chilling antimicrobial application and CCP 3 Chilling. Offline reprocessing procedures incorporated into HACCP system as a prerequisite program to comply with 9 CFR 381.91(b)(2). Written procedures to remove localized disease conditions (for example, airsacculitis, inflammatory processes) No", "Step Hazard RLTO Justification \ Basis Controls CCP Page 12 of 19 and verify that establishment employees appropriately implement the procedures in a sanitary manner. C: Inappropriate concentration of antimicrobial No Establishment historical data shows low risk of inappropriate chemical application. Written chemical mixing procedures and documented verification procedures to ensure that critical operating parameters are maintained. Chemicals are properly used to meet the chemical manufacturer\u2019s recommendations and GRAS parameters. P: None 7. Crop, Lung, and Kidney Removal B: Pathogens Salmonella, Campylobacter Yes Carcasses accidentally contaminated with digestive tract contents (feces and ingesta) at higher risk for pathogen contamination. Crop removal may cause ingesta contamination, which increases the risk for pathogens. Kidneys with disease conditions, including airsacculitis lesions are required to be removed from carcasses. The hazard is controlled at a later step with visual examination, antimicrobial application and chilling (CCP 1, CCP 2, CCP 3). Written Sanitary Dressing Procedures to prevent contamination of carcasses and parts by enteric pathogens and fecal contamination throughout the slaughter and dressing operations incorporated as a prerequisite program to meet 9 CFR 381.65(g) requirements. No C: None No P: None No 8. Carcass Wash B: Pathogens Salmonella, Campylobacter Yes Carcasses accidentally contaminated with digestive tract contents (feces and ingesta) at higher risk for pathogen contamination. The hazard is controlled at a later step with visual examination, antimicrobial application and chilling (CCP 1, CCP 2, CCP 3). Written program to monitor that the carcass wash functions as intended. No", "Step Hazard RLTO Justification \ Basis Controls CCP Page 13 of 19 C: Inappropriate concentration of antimicrobial No Establishment historical data shows low risk of inappropriate chemical application. Written chemical mixing procedures and documented verification procedures to ensure that critical operating parameters are maintained. Chemicals are properly used to meet the chemical manufacturer\u2019s

recommendations and GRAS parameters. P: None No 9. Trimming B: Pathogens Salmonella, Campylobacter No Employee hygienic practices. Operational Sanitation SOPs. C: None

10. Monitoring Carcasses, Parts and Giblets for Fecal Contamination B: Pathogens Salmonella, Campylobacter Yes Fecal material carries pathogens. Monitoring for fecal contamination prior to the pre-chill antimicrobial application to ensure that poultry carcasses contaminated with visible fecal material do not enter the chiller (9 CFR 381.65(f)). Written Sanitary Dressing Procedures to prevent contamination of carcasses and parts by enteric pathogens and fecal contamination throughout the slaughter and dressing operations incorporated as a prerequisite program to meet 9 CFR 381.65(g) requirements. No (zero) fecal contamination to enter chilling system. Examine the inside and outside surfaces of carcasses for fecal contamination at a Yes CCP 1","Step Hazard RLTO Justification \ Basis Controls CCP Page 14 of 19 23 If an establishment implements a process consistent with the process specifications described in the scientific support, and the scientific support contains microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, the in-plant validation data collected during the 90 day initial validation period will consist of data on quantifiable characteristics of the critical operational parameters, such as pressure, temperature, and concentration. However, if an establishment implements different critical operational parameters in the process from the scientific support, or the scientific support identified does not contain microbiological data, then the establishment should collect in-plant data demonstrating the critical operational parameters that it has implemented can all be met AND should collect in-plant microbiological validation data or identify scientific support with microbiological data that demonstrates the effectiveness of those implemented critical operational parameter (FSIS Compliance Guideline HACCP Systems Validation, page 27). 24 If products are ice chilled in vats the hazard analysis should address any hazards associated with ice manufacture, storage and handling. point prior to the pre-chill antimicrobial application. Examine parts and giblets for fecal contamination prior to chilling. C: None P: None

11. Pre-chilling Antimicrobial Application B: Pathogen outgrowth Salmonella, Campylobacter Yes Carcasses accidentally contaminated with digestive tract contents (feces and ingesta) at higher risk for pathogen contamination. CCP 2 Pre-chilling antimicrobial application. Application of organic acid solution to carcasses, parts, giblets, necks and feet.23 Yes CCP 2 P: None C: Inappropriate concentration of antimicrobial applied No Establishment historical data shows low risk of inappropriate chemical application. Written chemical mixing procedures and documented verification procedures to ensure that critical operating parameters are maintained. Chemicals are properly used to meet the chemical manufacturer\u2019s recommendations and GRAS parameters.

12. Chilling of all Products24 B: Pathogen Outgrowth Salmonella, Campylobacter Yes Delayed chilling may result in pathogen outgrowth. Pathogen outgrowth is controlled with CCP 3 Chilling. Apply chilling procedures to lower internal temperatures of carcasses, giblets, necks, and feet. Written chilling procedures that address, Yes CCP 3","Step Hazard RLTO Justification \ Basis Controls CCP Page 15 of 19 25 The FSIS Compliance Guide: Modernization of Poultry Slaughter Inspection: Chilling Requirements describes alternative chilling procedures granted under the Salmonella Initiative Program (SIP)(page 5). The alternative procedures are validated to prevent the outgrowth of pathogens as product is being chilled. 26 Post-chill Poultry Finished Product Standards tests monitor for extraneous materials in the chill media. The tests are performed every 2 hours of

production time in Streamlined Inspection System, New Line Speed Inspection System, and New Turkey Inspection System establishments 27 The establishment must prevent the outgrowth of pathogens on chilled product as long as the product remains at the establishment (9 CFR 381.66(b)(2)). The FSIS Compliance Guide: Modernization of Poultry Slaughter Inspection: Chilling Requirements includes the former regulatory provisions (\u201csafe harbors\u201d) that an establishment can implement to prevent the outgrowth of pathogens in chilled product (page 4). at a minimum, the potential for pathogen outgrowth, the conditions affecting carcass chilling, and when the chilling process is complete (9 CFR 381.66(b)(3)).25 C: Inappropriate concentration of antimicrobial No Establishment historical data shows low risk of inappropriate chemical application. Written chemical mixing procedures and documented verification procedures to ensure that critical operating parameters are maintained. Chemicals are properly used to meet the chemical manufacturer\u2019s recommendations and GRAS parameters. P: Foreign Material No Foreign material contamination from overhead structures and immersion system moving parts. Foreign Material SOP. Carcasses monitored 2 times per shift for extraneous material contaminants after chilling.26 13. Transfer Carcasses to Cut up or Further Processing B: Pathogen Outgrowth Salmonella, Campylobacter No Pathogen outgrowth may result if temperatures are not maintained at levels to prevent multiplication during transfer. Product is transferred to cut up or further processing to prevent product temperatures that promote pathogen outgrowth (Tompkin, R.B. 1996).27", "Step Hazard RLTO Justification \ Basis Controls CCP Page 16 of 19 C: None P: None 14. Packaging and Labeling B: Pathogens: Salmonella, Campylobacter No Pathogen outgrowth may result if temperatures are not maintained at levels to prevent multiplication. Product is packaged and placed in storage coolers or freezers to prevent product temperatures that promote pathogen outgrowth (Tompkin, R.B. 1996). C: None P: None 15. Cold Storage B: Pathogen Outgrowth Salmonella, Campylobacter No Pathogen outgrowth may result if temperatures are not maintained at levels to prevent multiplication during shipping. Written product storage procedures to maintain product at temperatures that prevent pathogen outgrowth (9 CFR 381.66(b)(1)(ii)). C: None P: None 16. Shipping B: Pathogen Outgrowth Salmonella, Campylobacter No Pathogen outgrowth may result if temperatures are not maintained at levels to prevent multiplication during shipping. Products shipped on refrigerated transport vehicles. C: None P: None 17. Returned Product Reinspection SOP implemented before accepting returned product. Product enters the appropriate step of the production system based on findings of product evaluation. Opened packages are not accepted. Notify FSIS personnel when product has been returned.", "Page 17 of 19 28 This example HACCP plan is best suited for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP model is for demonstration purposes only. The model does not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. 29 Each establishment must develop written corrective action procedures in response to a deviation from the critical limit to determine what to do with the affected product (from the last acceptable check), to eliminate the cause of the deviation, to bring the CCP back into control, and to prevent future deviations (CFR 417.3). EXAMPLE: Young Chicken Slaughter HACCP Plan28 Critical Control Point (CCP) Significant Hazard(s) Critical Limits for Each Control Measure Monitoring Procedures Corrective Action29 Verification Records What How Frequency Who CCP 1 Monitoring Carcasses, Parts and Giblets

for Fecal Contamination Pathogens: Salmonella, Campylobacter No fecal contaminants to enter chilling system. Visual examination for fecal material. Examine the inside and outside surfaces of 10 carcasses and all surfaces of 10 parts or giblets for fecal contaminants. Check 10 carcasses and 10 parts or giblets per production hour. Select random times to perform the checks. If less than 10 units are available examine all available units. Designated employee If a deviation from the critical limit occurs, a manager will, per 9 CFR 417.3(a): 1. Hold all product produced after last acceptable check until appropriate disposition taken (no product injurious to health will enter commerce); 2. Determine and eliminate the cause of the deviation; 3. Restore process control; 4. Take measures to prevent recurrence. A manager observes and then records the results of their verification of the CCP monitoring activity once each day of slaughter operations. A manager observes and then records the results of their observations of the corrective actions taken for each deviation from a critical limit. Records reviewed once a week 9 CFR 417.4(a)(2)(iii). Zero Fecal Check Form Corrective Action Log Preshipment Review Form", "Page 18 of 19 Critical Control Point (CCP) Significant Hazard(s) Critical Limits for Each Control Measure Monitoring Procedures Corrective Action Verification Records What How Frequency Who CCP 2 Prechilling Antimicrobial Application 30 Pathogens: Salmonella, Campylobacter 600-700 ppm organic acid solution31 Monitor the preparation and mixing of the antimicrobial solution. Monitor the application of the solution. Measure and record the amount of antimicrobial and the amount of water used to make the solution. Monitor the employee's application of the solution to carcasses, parts and giblets. Check the amount of antimicrobial and water used to make up the solution once per shift. The application of the solution is monitored twice per shift. Designated employees If a deviation from the critical limit occurs, the production supervisor will, per 9 CFR 417.3(a): 1. Hold all product produced after the last acceptable check until appropriate disposition taken (no product injurious to health will enter commerce); 2. Determine and eliminate the cause of the deviation; 3. Bring the CCP under control; 4. Take measures to prevent recurrence. Randomly, once per shift, a manager observes the monitoring activity and records their findings. Records Reviewed once per week (9 CFR 417.4(a)(2)(iii) Organic Acid Spray Concentration Form. Corrective Action Log Pre-shipment Review Form 30 If an establishment implements a process consistent with the process specifications described in the scientific support, and the scientific support contains microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, the in-plant validation data collected during the 90 day initial validation period will consist of data on quantifiable characteristics of the critical operational parameters, such as pressure, temperature, and concentration. However, if an establishment implements different critical operational parameters in the process from the scientific support, or the scientific support identified does not contain microbiological data, then the establishment should collect in-plant data demonstrating the critical operational parameters that it has implemented can all be met AND should collect in-plant microbiological validation data or identify scientific support with microbiological data that demonstrates the effectiveness of those implemented critical operational parameter (FSIS Compliance Guideline HACCP Systems Validation, page 27). 31 Scientific or technical support is required to validate the critical limits and critical parameters (for example, time of exposure) of the organic acid spray. They are part of the hazard analysis and need to be maintained for the life of the HACCP plan (see FSIS Compliance Guideline

HACCP Systems Validation); FSIS Directive 7120.1 Safe and Suitable Ingredients Used in the Production of Meat, Poultry, and Egg Products contains approved substances for use in poultry; however, each establishment must validate their own process.", "Page 19 of 19 Critical Control Point (CCP) Significant Hazard(s) Critical Limits for Each Control Measure Monitoring Procedures Corrective ActionError! For general guidance on establishing critical limits see the Guidebook for the Preparation of HACCP Plans (page 30)." ]}, {"file\_name": "FSIS\_GD\_2020\_0014", "title": "FSIS Guidance for a Suggested Reporting Table for the Certified Establishment List", "num": "FSIS-GD-2020-0014", "id": "c5e3d6d3b776af57b0a8746d563e634fec018224742a041aab20b04f715b6739", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/media\_file/2021-01/Suggested-Reporting-Table-Certified-Establishment-List.pdf", "type": "pdf", "n\_pages": 2, "word\_count": 1290, "text\_by\_page": ["1 FSIS Guidance for a Suggested Reporting Table for the Certified Establishment List By May 18th of each year, the Central Competent Authorities (CCAs) of countries wishing to maintain on-going equivalence and continue actively exporting meat, poultry, or egg products to the United States (U.S.) are required to provide the United States Department of Agriculture (USDA), Food Safety and Inspection Service (FSIS) an up-to-date list of all certified establishments used in the production of products eligible for export to the U.S. Therefore, if the production chain involves more than one establishment (e.g., beef is slaughtered at one establishment, further processed at a different establishment, packaged and labeled at yet another establishment, and then exported to the U.S. from a different establishment), each establishment in the production chain, including the establishment providing the raw source material and the storage facility from where the product is exported, must be listed on the certified establishment list. Furthermore,"]}

countries that are not eligible to export raw product directly to the U.S. (e.g., due to USDA Animal and Plant Health Inspection Service (APHIS) animal disease requirements), but are eligible to use their own raw source materials to produce processed products are required to certify and list the establishments providing the raw source materials. Lastly, when listing an establishment that provides raw source material, please clearly identify the establishment as a source establishment on the certified establishment list. The reporting table below may be used to assist CCAs with providing the required information to FSIS by May 18th of each year. The format of the table is optional; however, the information noted with an asterisk (\*) is required to be sent to FSIS annually. For each certified establishment, CCAs should only include products that the country is currently eligible to export to the U.S., including raw source materials for further processing. In addition, if your country is prevented from exporting certain meat, poultry, or egg products to the U.S. due to an APHIS animal disease requirement, FSIS requests that the CCA clearly identify the product categories and product groups that each certified establishment intends to export to the U.S. To view which products your country is currently eligible to export to the U.S., refer to FSIS Import Library- Eligible Countries and Products. For a list of product categories and product groups, please refer to the FSIS Product Categorization Guide. Certified establishments that are no longer eligible to export products to the U.S. must be identified as delisted on the list provided to FSIS. Furthermore, FSIS requests that CCAs inform FSIS of any establishment delisting within 90 days. CCAs can submit the required information to FSIS by either uploading it into our Public Health Information System (PHIS) under question 4 of the 2019 self-reporting tool (SRT), or by submitting it to our International Coordination Executive at: US Department of Agriculture Food Safety and Inspection Service, Office of International Coordination, Room 3143 South Building, 1400 Independence Ave SW, Washington D.C. 20250-3700 E-mail: InternationalCoordination@usda.gov Date\u00b9\*

Eligibility Status \u00b2\* Establishment Number\* Establishment Name\* Establishment Address\* Type(s) of Operation\u00b3\* Process Category\u2074\* Species\u2075 \* Product Category Product Group MMI/DD/YYYY 1. Date \u2013 The date of an establishment\u2019s initial certification, delisting, or relisting. 2. Eligibility Status \u2013 If an establishment listed on the previous year\u2019s certified establishment list remains eligible to export products to the U.S., please leave this field blank. \u2022 New - Establishments that are newly certified as eligible to export products to the U.S. that were not previously certified as eligible to export products to the U.S. \u2022 Delisted \u2013 Establishments that were previously certified as eligible to export products to the U.S. and are no longer eligible to export products to the U.S. \u2022 Relisted \u2013 Establishments that were previously delisted and have been relisted as certified as eligible to export products to the U.S. 3. Type(s) of Operation \u2013 Slaughterhouse, Non-Slaughter Processing, Egg Processing, Cold Storage, Exporting Warehouse, or Source Establishment. \u2022 Slaughterhouse \u2013 Establishments where healthy, live animals are humanely slaughtered under sanitary conditions to produce meat or poultry products for human consumption. \u2022 In slaughter operations, FSIS requires continuous government inspection during slaughter activities to ensure that each and every livestock carcass, head, and viscera and each and every poultry carcass and viscera are inspected. \u2022 Non-Slaughter Processing - Operations include all non-slaughter activities, including but not limited to, boning, cutting, slicing, grinding, injecting, pumping, filleting, breading, adding ingredients through other mechanical means, formulating, cooking, smoking, cooling,

assembling, and packaging." "FSIS Guidance for a Suggested Reporting Table for the Certified Establishment List 2 \u2022 In processing operations (i.e., non-slaughter), FSIS requires that a government inspector be on the premises and performing inspection activities at least once per production shift during processing operations. The requirement for government inspection once per production shift during processing operations is not the same as inspection once daily; therefore, if an establishment has more than one production shift per day during which it produces product for export to the U.S., a government inspector must be present at least once during each production shift. \u2022 Egg Processing - Manufacturing of egg products, including breaking eggs, filtering, mixing, blending, pasteurizing, stabilizing, cooling, freezing, drying, or packaging egg products at certified establishments. \u2022 Cold Storage \u2013 Facility that receives and stores meat, poultry, or egg products from certified establishments and maintains products under refrigeration until export to the U.S. \u2022 Exporting Warehouse \u2013 Facility that receives and stores meat, poultry, or egg products from certified establishments until export to the U.S. Additionally, the facility where export verification and certification services for exports are provided. \u2022 Source Establishment - Slaughter establishment that provides raw source materials to certified establishments for the production of processed products intended for export to the U.S. Source establishments are not eligible to export product directly to the U.S. due to disease restrictions, regionalization, product ineligibility, or other reasons. However, source establishments must meet all U.S. requirements, be certified by the CCA, and be identified as a source establishment on the certified establishment list. 4. Process Category \u2013 1. Eggs\Egg Products For the purposes of this document the term \u201cprocessed\u201d refers to raw meat or poultry product that has been modified through an additional processing step. Methods of processing meat and poultry products include, but are not limited to, cooking, salting, curing, aging, fermentation, and smoking. Simple mechanical processes (sometimes referred to as further processing) such as cutting, grinding, or mixing of raw meat or poultry product are not included in this definition. \u2022 Raw meat and poultry products may be produced and certified under the following FSIS Process Categories: \u2022 Raw Product - Non-Intact and \u2022 Raw Product \u2013 Intact. \u2022 Processed meat and poultry products may be produced and certified under the following FSIS Process Categories: \u2022 Thermally Processed - Commercially Sterile, \u2022 Not Heat Treated - Shelf Stable, \u2022 Heat Treated - Shelf Stable, \u2022 Fully Cooked - Not Shelf Stable, \u2022 Heat Treated - Not Fully Cooked -Not Shelf Stable, and \u2022 Products with Secondary Inhibitors - Not Shelf Stable. The term \"egg products\" refers to eggs that are removed from their shells for processing. 5. Species \u2013 F: fish of the order Siluriformes O: lamb\mutton (ovine) SQ: squab B: beef (bovine) P: pork (porcine) EM: emu V: veal D: duck OS: ostrich CH: chicken GO: goose R: rhea C: goat (caprine) GU: guinea T: turkey

This guidance covers: \u2022How to respond to customer complaints of adulterated or misbranded meat and poultry products \u2022The recall notification requirements in 9 CFR 418.2 FSIS Guideline for Industry Response to Customer Complaints 2020","2 Preface: FSIS developed this guideline to communicate what FSIS has identified as best practices for meat and poultry establishments to respond to customer complaints. The guideline was developed with appropriate review and public participation and has been revised in response to public comments. Some portions of the document have been rearranged to highlight FSIS recommendations for developing a customer complaint program and to further clarify existing FSIS regulatory requirements. This guideline follows the procedures in the Office of Management and Budget\u2019s (OMB) \u201cFinal Bulletin for Agency Good Guidance Practices\u201d (GGP). You can find more information on guidance documents on the Food Safety and Inspection Service (FSIS) Web page. The meat and poultry trade associations, along with their members, have developed a related document, Industry Best Practices for Customer Complaints of Foreign Material in Meat and Poultry Products. Establishment personnel may want to use guidance from both documents when developing a response to customer complaints. What is the purpose of this guideline? The purpose of this guideline is to inform industry of the procedures FSIS has identified as best practices for responding to customer complaints of adulterated and misbranded meat and poultry products. FSIS developed this document in response to an increase in the number of recalls of meat and poultry products adulterated with foreign materials. In many cases, the recalling establishment had received multiple customer complaints prior to these recalls. FSIS specifically developed this document to address foreign material customer complaints, but establishments can apply the information to other customer complaints of adulterated or misbranded products in commerce. This guideline represents FSIS\u2019s current thinking on this topic and should be considered usable as of the issuance date. Who is this guideline designed for? FSIS is issuing this document to assist all FSIS-regulated meat and poultry establishments in developing and implementing procedures for responding to customer complaints, and in preventing similar adulteration or misbranding occurrences. Does the guidance reflect requirements? This document is not regulatory. An establishment may choose to adopt different procedures than those outlined in this guideline. This guideline recommends each establishment develop a customer complaint program. However, an establishment can operate without a customer complaint program because there is no regulatory requirement to develop or implement a program to address customer complaints. If an establishment voluntarily decides to develop a customer complaint program, there is no requirement that a program be incorporated into its Hazard Analysis and Critical Control Point (HACCP) system. Customer complaints occur after the product has left the establishment, so a program to respond to complaints is not preventing hazards or adulteration. However, when a customer complaint results in findings of adulterated products, the establishment must meet applicable requirements as described below."],"3 What if I still have questions after I read this guideline? FSIS recommends that users search the

publicly posted Questions & Answers (Q&As) in the askFSIS database or submit questions through askFSIS. Documenting the questions helps FSIS improve and refine present and future versions of the guideline and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter FSIS Guideline for Industry Response to Customer Complaints. Question Field: Enter question with as much detail as possible. Product Field: Select General Inspection Policy from the drop-down menu. Category Field: Select Regulations\Agency Issuances from the drop-down menu. Policy Arena: Select Domestic (U.S.) Only from the drop-down menu. When all fields are complete, press Continue.","4 FSIS Guideline for Industry Response to Customer Complaints Table of Contents Preface:

Background: FSIS is the public health regulatory agency responsible for ensuring that the nation\u2019s commercial supply of meat, poultry, and egg products is safe, wholesome, and correctly labeled and packaged. In 2008, Congress amended the Federal Meat Inspection Act (FMIA) and the Poultry Products Inspection Act (PPIA) to require each establishment to promptly notify the Secretary if they believe, or have reason to believe, that adulterated or misbranded meat or poultry products have entered into commerce (21 U.S.C. 612 and 459(b)). The Secretary delegated this responsibility to FSIS. In 2012, FSIS issued final regulations reflecting these requirements (9 CFR part 418). Since the implementation of the regulation in May 2012, FSIS has observed an increase in the number of recalls associated with foreign materials and has developed this guideline to assist establishments in responding to complaints and meeting related regulatory requirements, when applicable. FSIS recommends, but does not require, that each establishment develop a program to receive and process customer complaints concerning possibly adulterated or misbranded products in commerce. When an establishment chooses to implement a customer complaint program, FSIS recommends it develop and maintain a program that addresses the receipt and investigation of complaints, the implementation of corrective actions, and the notification of FSIS that adulterated or misbranded products have entered commerce. A discussion of regulatory requirements is	

included later in the guideline; however, a customer complaint program is not a regulatory requirement. The regulatory requirements are included for informational purposes and may result in a more robust customer complaint program. KEY QUESTION Question: Is a meat or poultry establishment required to notify FSIS every time they have reason to believe that an adulterated or misbranded product has entered commerce? Answer: Yes, under 9 CFR 418.2, each establishment is required to notify the District Office within 24 hours of learning or determining that they have received or shipped into commerce adulterated or misbranded meat or poultry products. When a receiving establishment notifies FSIS inspection personnel, the establishment is in compliance with this regulation. The producing establishment is not expected to also notify FSIS if the receiving establishment has already notified the Agency of the issue.","6 Developing a Customer Complaint Program: \uf0d8 Overview of the Program A well-developed and implemented customer complaint program provides many benefits including assisting the establishment in complying with other regulatory requirements and reducing the long-term financial costs of recalls. A consumer complaint program should include the following components (discussed in more detail in this guideline): \uf0d8 Customer Complaint Reporting \uf0d8 Substantiation of a Customer Complaint \uf0d8 Response to a Customer Complaint o Establishment Response Plan and Investigation \uf0d8 Documentation of a Customer Complaint \uf0d8 Related Regulatory Requirements o FSIS Notification (when required by 9 CFR 418.2) o Corrective Actions (when required by 9 CFR 416.15 or 417.3) \uf0d8 Customer Complaint Reporting Customer complaints may originate from: another establishment, a household consumer, the USDA Consumer Complaint Monitoring System (CCMS), or another regulatory agency<sup>1</sup>. Regardless of the source, each customer complaint should be evaluated as a possible report of adulterated or misbranded products in commerce. Each establishment should develop appropriate mechanisms to receive and process customer complaints. The establishment should provide household consumers with a method for reporting a complaint, for example: \u2022 Postal address; \u2022 Toll-free number; \u2022 Website address; or \u2022 E-mail address. The establishment should provide non-household consumers (e.g., other establishments, hotels, restaurants, or institutions) with a method for reporting a complaint, for example: \u2022 Company representative contact information; or \u2022 Instructions within the contract or bill of lading. 1 Although other regulatory agencies are not \u201ccustomers\u201d they are included as possible sources of complaints and may be included in a robust program.","7 As technology and social networking change, other methods for reporting complaints may be developed and incorporated into the customer complaint program. The establishment may provide contact information and methods to report a complaint on product labels, shipping documents, or can post this information on the company\u2019s webpage. An establishment that re-labels or co-packs products should be aware that a customer might direct complaints to the company name on the label. As a result, FSIS recommends that co-packers work with the company named on the label to develop a method for reporting and tracking complaints. When the establishment uses a thirdparty contractor to collect and process customer complaints or when complaints are directed to a corporate address, the establishment should consider how these complaints will be relayed to the producing establishment. The establishment customer complaint process may also include quality complaints; however, a system should be in place to prioritize or triage those complaints that indicate adulterated or misbranded meat or poultry products have been produced at the

establishment. \uf0d8 Substantiation of the Customer Complaint An establishment should develop criteria and a mechanism for reviewing any customer complaint. The establishment should verify where the products were produced. Products are often similar and may be produced at multiple locations, so the establishment should verify that the products were produced at its location and, if not, notify the customer or other establishment when appropriate. The establishment should also develop criteria to determine whether tampering of the products occurred after shipment from the producing establishment. The establishment should determine what evidence, if any, the customer has of the adulteration and misbranding. Information that can be used to substantiate a claim includes: \u2022 Evidence of the physical contaminant, \u2022 Photographs, \u2022 Video, or \u2022 A sample of the product label, product, and any other applicable material. The product label provides information to verify the source of the product, including the lot number, establishment number, and product name. An image or a sample of the product provides information to verify that the product matches the label and can show the condition of the product. An image or a sample of any physical adulteration, such as foreign material, provides information that can be used to start the investigation into the cause of the adulteration. The purchase location may also be helpful to identify distribution channels that may have contributed to the adulteration or misbranding.

NOTE: If the product does not match the label, this could be the basis of a misbranding claim and should be evaluated as evidence of misbranding. Each establishment should begin to substantiate complaints as soon as possible when there is the possibility that adulterated products have been purchased by household consumers. Products available at the level of the household consumer add a degree of", "8 urgency to removing adulterated products before they are consumed, especially when the adulteration is a food safety hazard. At this point in the process, initial substantiation, it may not be possible to determine if the adulteration is a food safety hazard, so it is important to move quickly to gather information. When the establishment determines that hands-on examination of the products, labels, or any other material is important in determining whether adulterated products have been produced, it should not delay the shipment of the identified foreign objects, samples of the products, or labels for examination by the producing establishment. The FSIS recommended practice is to perform an initial substantiation and investigation using immediately available photographic or video evidence and take appropriate action based on that evidence and then follow up with additional actions, as warranted, if the physical material, products, or labels are made available for a hands-on examination. As soon as the establishment has reason to believe adulterated or misbranded products have entered commerce, then FSIS must be notified per 9 CFR 418.2. It may not be necessary to perform a physical examination of the products, material, or labels to have reason to believe adulterated products have entered commerce. For example, some customers may be able to provide a credible description of the product with adequate detail to have a reasonable belief that adulterated products entered commerce. Also, multiple reports of similar foreign materials, especially when the initial report has been validated, may be enough to take action without any physical evidence from the additional reports of adulteration. If there is epidemiological evidence that a specific product is implicated in a series of injuries or illness, that may be enough evidence to substantiate that adulterated products have entered commerce, without observing foreign material. Reports of adulterated or misbranded products from customers other than a household consumer are also critical and should be prioritized

over quality complaints. Quick action on these complaints can prevent distribution to households and consumer injury. The establishment should identify the specific establishment employee(s) (name or title) who will receive notification of complaints and will be responsible for their initial substantiation. Since complaints may occur on weekends, FSIS recommends that applicable contact information be included in the program. Early action is critical to identifying products in distribution channels, correcting the issue to prevent further adulteration or misbranding, and removing adulterated or misbranded products from households before they are consumed. When an establishment determines that a customer complaint claim is not valid or not applicable to FSIS-regulated products, FSIS recommends that the establishment maintain documentation to support how that decision was made. Such documentation Recommendation Each establishment should develop the criteria and mechanisms for determining if the products were produced at that establishment, if a customer complaint is genuine, authentic, and that no tampering of the products occurred after shipment from the producing establishment." "9 could be used to support why the establishment did not take any actions related to the products, especially if new evidence, which does support the initial claim, is identified in the future. The establishment must consider if any FSIS-regulated products are implicated by a complaint. The initial complaint may be related to a product under Food and Drug Administration (FDA) jurisdiction; however, when there are common ingredients or common production areas, the possible contamination of FSIS-regulated products must be considered. It is not an FSIS regulatory requirement to maintain documentation related to products that are not regulated by FSIS or whose production does not impact FSIS-inspected products. However, an establishment may want to maintain documentation regarding complaints about the FDA products that it produces and must comply with any FDA regulations regarding reporting and recalling adulterated products. NOTE: A valid complaint for products under FDA jurisdiction must be addressed as required by FDA regulations. Some examples of why a complaint may be found to be without merit related to FSIS principles include: \u2022 Implicated products not produced, distributed by, or owned at any point by an establishment or corporation. \u2022 A valid complaint determined not to involve an FSIS food safety hazard, adulterated products, or misbranding, e.g., a complaint about quality. \u2022 Products that are not under FSIS jurisdiction and there are no implications for FSIS-inspected products. When the establishment has identified a valid complaint and believes, or has reason to believe, that adulterated or misbranded products shipped or received by the establishment have entered commerce, the establishment must notify the FSIS District Office within 24 hours (9 CFR 418.2). Depending on the procedures used to validate the complaint, further investigation may or may not be required to make this determination. When an establishment receives a customer complaint and it is substantiated, the next two questions to ask are: 1) Is the product adulterated or misbranded? and 2) Has it entered commerce? What are adulterated or misbranded products? Adulterated: Meat or poultry products that are injurious to health or are for any other reason unsafe, unsound, unhealthful, unwholesome, or otherwise unfit for human food. Misbranded: Meat or poultry products that bear a false or misleading label or if any required feature is not prominent." "10 \uf0d8 What are adulterated or misbranded products? Meat or poultry products are adulterated, among other reasons, if they bear or contain any poisonous or deleterious substance that may render them injurious to health; are unhealthful, unwholesome, or otherwise unfit for human consumption; or were prepared, packaged, or held

under insanitary conditions whereby they may have been rendered injurious to health (see 21 U.S.C. 453(g) and 21 U.S.C. 601(m)). Meat or poultry products are misbranded if the label is false or misleading, or if it does not contain the required labeling features (see 21 U.S.C. 453(h) and 21 U.S.C. 601(n)). Meat and poultry products that are contaminated with foreign materials are adulterated under the FMIA and PPIA regardless of the physical characteristics of the foreign material (e.g., shape, size, hardness, etc.) because foreign materials are unfit for human consumption, may contain poisonous or deleterious substances, and may indicate conditions of filth. Material that is inherent to the species (e.g., bone, hide, feathers) can result in adulterated or misbranded products when the contamination\u2019s extent, size, or shape would render the products unwholesome or injurious to health. The establishment should evaluate each complaint and finding in the context of the specific product, intended use, HACCP system, and details of each incident to determine when meat or poultry products are adulterated. \uf0d8 When are products in commerce? An official establishment is required to report to FSIS when they believe, or have reason to believe, adulterated or misbranded products have entered commerce. In the context of this document and 9 CFR 418.2, FSIS considers products to have entered commerce when the products have left the direct control of the producing establishment and are in distribution. This includes products at retail and products moving between official establishments or other consignees and not yet available to institutional or household consumers at the retail level. FSIS considers the following to be indications What is \u201cin commerce\u201d? When products are not under the direct control of the producing establishment and are in distribution, they have entered commerce, this can include movement between FSISinspected establishments. \u2022 FSIS considers products to be in commerce when preshipment review is signed (unless there are other written methods to demonstrate direct control) and the products are in distribution. \u2022 Individual determinations are made on a case-by-case basis using information including the establishment procedures to demonstrate direct control and the physical location of the products.", "11 that the producing establishment maintains direct control of products, provided the controls are sufficiently documented and HACCP system decisions are consistent with the expressed controls: \u2022 Products are moved between two establishments owned by the same corporation, under a tamper-resistant seal applied by the producing establishment. \u2022 Products are at the establishment or located on premises owned or operated by the producing establishment. There may be other methods for an establishment to demonstrate it has maintained direct control of the products. New technologies and other innovation are continually implemented to improve product movement and this document is not intended to capture all possibilities. When considering new technologies, business models, and distribution, an establishment may want to consider these questions to determine if they are maintaining direct control: \u2022 Who owns the products now? \u2022 Can we prevent an employee (possibly of a different company) from physically moving\using the products? \u2022 What do we have in writing to demonstrate control? \u2022 If we needed to get the products back to our establishment, can we do so without involving other companies? \u2022 Do we have direct control of all comingled (possibly affected) products? \u2022 Has preshipment review been signed? This list is not all inclusive and the answers can vary, but these are the types of questions an establishment can ask when developing a distribution system or evaluating a current distribution system, to determine where \u201cdirect control\u201d stops and the

products have entered commerce. One method an establishment may use to demonstrate direct control and determine when products have entered commerce is by using preshipment review. As required in 9 CFR 417.5(c), prior to shipping products into commerce, the establishment must review the production records of the product, making sure that all processing requirements were met and, if necessary, all corrective actions were taken. The establishment should not sign preshipment review until it has reviewed all lot-specific documentation. Lot-specific documentation includes all records associated with that specific production including, but not limited to, critical control point (CCP) monitoring, HACCP verification, corrective actions, prerequisite programs, testing, and any other applicable programs associated with the production of that lot. Preshipment review indicates that the product has been determined to be free from food safety hazards as well as other causes of adulteration and is ready for commerce. The review of the appropriate documents and compliance with 9 CFR 417.5(c) occurs before the product leaves the control of the producing establishment and enters commerce. This review may occur when products are at a location other than the producing establishment, as long as the producing establishment maintains control of the products."

"12 \uf0d8 Establishment Response to a Customer Complaint When an establishment receives a customer complaint and determines that adulterated or misbranded products have entered commerce, the establishment should perform an investigation to determine the appropriate corrective actions. While a written plan for addressing customer complaints is not a regulatory requirement, it may be helpful to facilitate training and to document corrective actions. The establishment should quickly identify all affected products (e.g., lot, date, line) and identify where they were distributed. This is an important step in stopping further distribution and in implementing the establishment\u2019s recall plan. The FSIS recommended best practice is to draft and maintain a written response plan. The response plan should include:

- Investigation of the production that incorporates a review of relevant records generated during the production of the affected products;
- Performing a visual inspection of any questionable products or labels available at the establishment;
- Observing ongoing production of like products; and
- Talking to employees who may have information pertinent to the investigation.

Affected products that have not been shipped should be held and inspected prior to shipping so the establishment can determine if there are additional adulterated or misbranded products. The establishment should use additional information to evaluate the design and implementation of the HACCP system, including laboratory sampling results, intended use of the products, supporting documentation, and expert analyses. The establishment is required to maintain a written recall plan (9 CFR 418.3). Because some customer complaints may result in a recall, an establishment may choose to incorporate a customer complaint response into the recall plan. If the establishment determines that adulterated (and in some cases misbranded) products have been produced and shipped, the establishment must meet any applicable regulatory requirements, as discussed further below, under \u201cCorrective Action Requirements\u201d. \uf0d8 Documentation of the Customer Complaint The FSIS recommended best practice is for an establishment to document all customer complaints (whether substantiated or not), to 21 U.S.C. 610 and 458 Prohibited acts No person, firm, or corporation shall sell, transport, offer for sale or transportation, or receive for transportation, in commerce, any such articles which are capable of use as human food and are adulterated or misbranded at the time of such sale,

transportation, offer for sale or transportation or receipt for transportation.", "13 include the investigative steps that were performed, and to describe how the claim was or was not substantiated. For substantiated claims of adulterated or misbranded products in commerce, the records should include how FSIS was notified, what corrective actions were performed, if a HACCP reassessment was performed, and the result of the reassessment. If the establishment did not reassess its HACCP plan, FSIS recommends that the establishment document how determinations were made and what evidence was used, even when a claim was not substantiated. If an FSIS investigation occurs at a future date and the establishment has documentation to support that past complaints were not substantiated, the documentation will help resolve the investigation and address questions about the complaint. The establishment should make records related to customer complaints available to FSIS for review upon request as required by 9 CFR part 320, 416.16, 417.5, and 418.4. Records of the investigations should include the following information (where applicable): \u2022 Dates of the complaint, any notification, corrective actions, recalls, etc.; \u2022 How the complaint was or was not substantiated; \u2022 Pictures; \u2022 Summary of the complaint including the complainant information; \u2022 Establishment number\ manufacturing location on the product label; \u2022 Injury or illness reported; \u2022 Product details and trace back information (product code, lot numbers, date codes); \u2022 Nature of foreign material (physical characteristics), as applicable; \u2022 Nature of misbranding, label information, label approval; \u2022 Notification of FSIS (who was notified, when, how); \u2022 Potential causes or contributing factors; \u2022 Other implicated products (same line, date, lot, ingredients, establishment); \u2022 Corrective actions, when applicable; \u2022 Preventive measures, when applicable; and \u2022 HACCP system reassessment, when applicable. The investigation documentation should also include how the establishment identified all implicated products and support for the determination. The establishment may wish to consider factors such as the physical layout of the establishment, Sanitation Standard Operating Procedures (SOPs), cleaning records, or testing results when developing the program to identify products that may be implicated by a complaint. The affected products will depend on the nature of the complaint. FSIS Regulatory Requirements Although the customer complaint program described in this guideline is not a regulatory requirement, the establishment may be required to perform certain actions in response to a finding of adulterated or misbranded products. Beyond the documentation and recordkeeping requirements already mentioned, several additional regulations outline the regulatory requirements an official establishment must meet to prevent direct", "14 contamination or adulteration of products or to respond to a finding of adulterated products. If a customer complaint credibly indicates that adulterated or misbranded products have entered commerce, the establishment must meet the reporting requirements of 9 CFR 418.2 as described in the \u201cFSIS Regulatory Requirements: Notification\u201d section below. If the outcome of a customer complaint investigation shows that the establishment produced adulterated products, the establishment must prevent affected products from entering commerce and, if necessary, remove products which may have already entered commerce. Depending on the nature and cause of the adulteration and how that type of adulteration is addressed in the HACCP system, the establishment must meet any applicable corrective action requirements. These requirements are described in the \u201cFSIS Regulatory Requirements: HACCP System\u201d section below. The establishment must also consider any relevant

customer complaint findings with respect to the design of the HACCP system in accordance with these general regulatory requirements: Notification 9 CFR 418.2 \u2013 \u201cEach official establishment must promptly notify the local FSIS District Office within 24 hours of learning or determining that an adulterated or misbranded meat, meat food, poultry, or poultry product received by or originating from the official establishment has entered commerce, if the official establishment believes or has reason to believe that this has happened. The official establishment must inform the District Office of the type, amount, origin, and destination of the adulterated or misbranded product.\u201d Hazard Analysis 9 CFR 417.2(a)(1) \u2013 \u201cEvery official establishment shall conduct, or have conducted for it, a hazard analysis to determine the food safety hazards reasonably likely to occur in the production process and identify the preventive measures the establishment can apply to control those hazards. The hazard analysis shall include food safety hazards that can occur before, during, and after entry into the establishment.\u201d Reassessment 9 CFR 417.4(a)(3)(i) \u2013 \u201cEvery establishment shall reassess the adequacy of the HACCP plan at least annually and whenever any changes occur that could affect the hazard analysis or alter the HACCP plan. Such changes may include, but are not limited to, changes in: raw materials or source of raw materials; product formulation; slaughter or processing methods or systems; production volume; personnel; packaging; finished product distribution systems; or, the intended use or consumers of the finished product. The 24 hours starts when the establishment has reason to believe that adulterated or misbranded products may have entered commerce", "15 reassessment shall be performed by an individual trained in accordance with \u00a7417.7 of this part. The HACCP plan shall be modified immediately whenever a reassessment reveals that the plan no longer meets the requirements of \u00a7417.2(c) of this part.\u201d Sanitation SOP 9 CFR 416.12(a) - \u201cThe Sanitation SOPs shall describe all procedures an official establishment will conduct daily, before and during operations, sufficient to prevent direct contamination or adulteration of product(s).\u201d Maintenance of Sanitation SOPs 9 CFR 416.14 \u2013 \u201cEach official establishment shall routinely evaluate the effectiveness of the Sanitation SOP's and the procedures therein in preventing direct contamination or adulteration of product(s) and shall revise both as necessary to keep them effective and current with respect to changes in facilities, equipment, utensils, operations, or personnel.\u201d Sanitation Performance Standards 9 CFR 416.4(d) - \u201cProduct must be protected from adulteration during processing, handling, storage, loading, and unloading at and during transportation from official establishments.\u201d Recalls 9 CFR 418.3 - \u201cEach official establishment must prepare and maintain written procedures for the recall of any meat, meat food, poultry, or poultry product produced and shipped by the official establishment. These written procedures must specify how the official establishment will decide whether to conduct a product recall, and how the establishment will effect the recall, should it decide that one is necessary.\u201d FSIS Regulatory Requirements: Notification Once the establishment has reason to believe that adulterated or misbranded FSIS regulated products have entered commerce, they must notify FSIS as required by 9 CFR 418.2. The producing establishment must notify the FSIS District Office and the receiving establishment must notify either the FSIS District Office or FSIS inspection personnel. Contact information for notification is provided on the webpage [www.fsis.usda.gov](http://www.fsis.usda.gov) contact us. When FSIS personnel notify the official establishment that adulterated or misbranded products have entered commerce, it would be redundant for the

establishment to also notify the District Office of the same adulterated or misbranded products and this could result in duplicate cases. Thus, when an establishment is notified by FSIS personnel that adulterated or misbranded products have entered commerce, the establishment does not need to notify the FSIS District Office unless additional product or production dates are involved. Remember, \u201cin commerce\u201d includes movement between official establishments when the products are not under direct control of the producing establishment or have left the direct control of the producing establishment at any point. It is also a good practice to notify the District Office of the nature of the adulteration or misbranding (e.g., foreign material contamination, ingredient not present on the label, etc.). The specific nature of", "16 each incident will determine the actions taken by FSIS in response to an official establishment producing adulterated or misbranded products that entered commerce. FSIS recommends that the establishment include in the response plan how it will gather the information required in 9 CFR 418.2 for notification of the District Office when products have been shipped in commerce. The information required in 9 CFR 418.2 is: \u2022 Product type \u2022 Amount of implicated products \u2022 Origin \u2022 Destination When an establishment believes, or has reason to believe, that adulterated or misbranded products have entered commerce, the establishment must notify FSIS within 24 hours. The 24-hour period includes weekends or non-workdays. If an establishment believes, or has reason to believe, that adulterated or misbranded products have entered commerce on a Friday, they must still report it within 24 hours even if the establishment does not operate on Saturday. The regulation applies to both producing and receiving official establishments. If a producing establishment discovers that their products are adulterated or misbranded while the products are still under their direct control, they are not required by 9 CFR 418.2 to notify the District Office. When an establishment is unsure if a finding should be reported to FSIS, they should ask Inspection Program Personnel (IPP) or the District Office for clarification. 9 CFR 418.2 vs. FSIS Directive 8140-1 The regulatory requirement in 9 CFR 418.2 to notify the District Office when adulterated or misbranded products have entered commerce applies to official establishments. This regulatory requirement is separate from the instruction to FSIS inspection personnel found in FSIS Directive 8140.1, Notice of Receipt of Adulterated or Misbranded Product. FSIS Directive 8140.1 instructs FSIS personnel to use an internal notification tool when adulterated or misbranded products have moved between establishments, even if those products have not entered commerce. The instructions in FSIS Directive 8140.1 concern verification of existing recordkeeping regulations (9 CFR part 320, 416.16, 417.5, and 418.4) and do not create a new notification requirement for establishments. FSIS personnel are responsible for gathering information, completing FSIS Form 81401, and following the instructions in FSIS Directive 8140.1. The establishment is responsible for meeting the regulatory requirement as described in 9 CFR 418.2 and for providing information when requested by FSIS personnel to complete FSIS Form 81401. The notification requirements for the receiving and producing establishments are further discussed below. Responsibilities at the Receiving Establishment", "17 When an establishment receives adulterated or misbranded products and the products have entered commerce, the receiving establishment must notify FSIS in accordance with 9 CFR 418.2. The receiving establishment may notify the District Office directly using the contact information provided on the FSIS Contact Us page or notify IPP. If the receiving establishment elects to notify IPP instead of the District Office, then IPP will complete a paper or digital FSIS Form 8140-

1 to notify IPP at the shipping\producing establishment and the applicable District Offices. Notification should only be done using official FSIS email addresses, phone numbers for FSIS offices, FSIS programs such as PHIS, and FSIS issued electronic devices. NOTE: The receiving establishment is required per 9 CFR 418.2 to either notify the District Office directly or IPP, but not both. Even though FSIS will provide a copy of FSIS Form 8140-1 to the producing establishment, FSIS recommends that the receiving establishment notify the producing establishment to expedite the producing establishment\u2019s investigation. Responsibilities at the Producing Establishment The producing establishment must provide notification to the District Office consistent with 9 CFR 418.2 when they have reason to believe adulterated or misbranded product has entered commerce. The producing establishment may find out about the adulterated or misbranded products directly from the receiving establishment, from a customer, or from local IPP. The producing establishment must notify its District Office within 24 hours of learning or determining that adulterated or misbranded products have entered commerce. Learning of the event provides an establishment reason to believe that adulterated or misbranded products have entered commerce and a final investigation does not need to be completed before FSIS notification. When the producing establishment receives a customer complaint from a location other than an official establishment (e.g., state inspected establishment, retail store, restaurant, household consumer, foreign establishment, foreign consumer, etc.) that indicates adulterated or misbranded products have entered commerce, then the producing establishment is solely responsible for the notification of the District Office. NOTE: When FSIS personnel at the producing establishment receive e-mail notification from the District Office of products that have been shipped in commerce and discuss the report with the producing establishment, the producing establishment is not required to provide any additional notification to the District Office under 9 CFR 418.2, unless they identify additional implicated products. IPP will verify the producing establishment\u2019s corrective actions according to the instructions in FSIS Directive 5000.1, Verifying an Establishment\u2019s Food Safety System. When adulterated or misbranded products have entered commerce, the Agency may determine the need to convene the Health Hazard Evaluation Board (HHEB) as per FSIS Directive 8091.1, Procedures for the Food Safety and Inspection Service (FSIS) Health Hazard and Evaluation Board (HHEB). The HHEB may be convened if there are circumstances that require further evaluation. Additionally, factors that are considered by the FSIS recall committee in evaluation of the public health significance of an", "18 undeclared ingredient in meat or poultry products are described in Attachment 2 of FSIS Directive 8080.1, Recall of Meat and Poultry Products. An establishment may wish to use FSIS Directive 8080.1 as a reference when developing its customer complaint program and when determining when a food safety hazard exists. Attachment 2 is specific to ingredients, but a similar thought process could be used to assess foreign materials, other contamination, and misbranding. FSIS Regulatory Requirements: HACCP System Does a customer complaint impact the establishment\u2019s HACCP System? One part of responding to a customer complaint is determining what aspect of the establishment\u2019s programs failed to prevent the adulterated or misbranded products from entering commerce. The establishment\u2019s HACCP system consists of the plans, programs, measures, and procedures that are implemented to prevent, eliminate, or control identified food safety hazards and other adulteration in their products. The HACCP system includes the HACCP plan and Sanitation SOPs, prerequisite programs, and other plans in

operation at an establishment to prevent products from becoming adulterated. Each establishment should customize the program for their unique products, operations, and system. The establishment's HACCP system should function to prevent any adulterated products from entering commerce, even if the cause of the adulteration is not a food safety hazard (e.g., it does not result in a food to be unsafe for human consumption). For example, an establishment may determine that a specific foreign material does not pose a physical or chemical food safety hazard in the product; however, the presence of the foreign material in a food causes that food to be adulterated and unfit for human consumption. Each establishment must prevent human food containing foreign material from entering commerce through the proper design and implementation of its HACCP system. 9 CFR 417.6 indicates that an establishment's HACCP system may be inadequate if the establishment produced or shipped adulterated products. In addition, 9 CFR 500.3 authorizes FSIS to withhold the mark of inspection or suspend inspection when an establishment has produced and shipped adulterated or misbranded products. Corrective Action Requirements When adulterated products have been produced, the establishment must determine what part of the HACCP system failed to allow products to become adulterated. The incident may have occurred because of a deficiency in the Sanitation SOPs, HACCP plan, or a prerequisite program. The system must be evaluated to determine if safe and wholesome products can still be produced under the existing system or if modifications must be made. The specific requirements for corrective actions depend on which part of an establishment's HACCP system addresses foreign materials as described below. The HACCP regulations require corrective actions when a food safety hazard occurs (9 CFR 417.3). 9 CFR 417.3(a) describes the corrective actions that apply when the establishment determines that the adulterated products represent a deviation from a "19 critical limit and states, \u201cThe written HACCP plan shall identify the corrective action to be followed in response to a deviation from a critical limit. The HACCP plan shall describe the corrective action to be taken, and assign responsibility for taking corrective action, to ensure: (1) The cause of the deviation is identified and eliminated; (2) The CCP will be under control after the corrective action is taken; (3) Measures to prevent recurrence are established; and (4) No product that is injurious to health or otherwise adulterated as a result of the deviation enters commerce.\u201d The second part of the regulation, 9 CFR 417.3(b) describes the corrective actions that apply when the establishment determines that the adulterated products represent an unforeseen food safety hazard and states, \u201c(b) If a deviation not covered by a specified corrective action occurs, or if another unforeseen hazard arises, the establishment shall: (1) Segregate and hold the affected product, at least until the requirements of paragraphs (b)(2) and (b)(3) of this section are met; (2) Perform a review to determine the acceptability of the affected product for distribution; (3) Take action, when necessary, with respect to the affected product to ensure that no product that is injurious to health or otherwise adulterated, as a result of the deviation, enters commerce; (4) Perform or obtain reassessment by an individual trained in accordance with \u00a7417.7 of this part, to determine whether the newly identified deviation or other unforeseen hazard should be incorporated into the HACCP plan.\u201d If the establishment determines that the adulteration does not represent a food safety hazard, the Sanitation SOP regulations describe the corrective actions that must be performed: \u201cEach official establishment shall take appropriate corrective action(s) when either the establishment or FSIS determines that the establishment's

Sanitation SOP's or the procedures specified therein, or the implementation or maintenance of the Sanitation SOP's, may have failed to prevent direct contamination or adulteration of product(s). Corrective actions include procedures to ensure appropriate disposition of product(s) that may be contaminated, restore sanitary conditions, and prevent the recurrence of direct contamination or adulteration of product(s), including appropriate reevaluation and modification of the Sanitation SOP's and the procedures specified therein or appropriate improvements in the execution of the Sanitation SOP's or the procedures specified therein (9 CFR 416.15). It is important to consider each customer complaint on a case-by-case basis. When a complaint is reported, the establishment must determine if a food safety hazard exists. If a food safety hazard has occurred, the establishment must address the regulatory requirements for HACCP corrective actions in 9 CFR 417.3 and records as required in 9 CFR 417.5. If a food safety hazard does not exist, the products may still be adulterated, and the establishment must react accordingly. If no food safety hazard exists, the regulatory requirements for adulterated products in 9 CFR 416.15 and 9 CFR 416.16 Reassessment: A HACCP reassessment is required when an establishment is performing corrective actions for an unforeseen hazard or when a change occurs that impacts the Hazard Analysis or HACCP plan. A Sanitation SOP must be revised as necessary to keep them current and effective in preventing direct contamination or adulteration of the products." "20 apply. Either way, when adulterated products have been produced and shipped, the establishment must implement a corrective action. The specific corrective action requirements are determined by the applicable regulation. HACCP corrective actions If a food safety hazard posed by foreign material was previously identified as reasonably likely to occur (RLTO), a CCP was established to prevent the hazard from entering commerce, and the hazard then does occur in products in commerce, the establishment must implement corrective actions as described in 9 CFR 417.3(a). If the food safety hazard posed by the foreign material was identified through the hazard analysis as not reasonably likely to occur (NRLTO) due to a prerequisite program, but it does occur and foreign material entered commerce, then it would be an unforeseen hazard and the establishment must perform corrective actions as described in 9 CFR 417.3(b). This corrective action requirement includes a reassessment to determine if the decision in the hazard analysis is still supportable or if changes need to be made. HACCP corrective actions must be documented as described in 9 CFR 417.5. If products are adulterated and in commerce but the cause of the adulteration (e.g., foreign material) is determined not to be a food safety hazard, the establishment must still evaluate the efficacy of its HACCP system. Adulterated products that have been produced or shipped may indicate an inadequate HACCP system. Sanitation SOP corrective actions Sanitation SOPs must be designed to prevent the contamination or adulteration of products as outlined in 9 CFR 416.12(a). When adulterated food products are found in commerce, the Sanitation SOP may have failed to prevent adulteration of products and the establishment must perform corrective actions as described in 9 CFR 416.15 and document the corrective actions as described in 9 CFR 416.16. The 9 CFR 416.15 Sanitation SOP corrective action regulation applies when adulterated food products have been produced and shipped even when the program that failed is not specifically included in the Sanitation SOPs (e.g., equipment maintenance, employee tool sign-out). The establishment will have to determine if the programs need to be incorporated into the Sanitation SOPs in order to prevent future adulteration as part of the routine evaluation of Sanitation SOPs described in 9 CFR

416.14. Misbranding corrective actions The establishment must not discount misbranding as a labeling issue alone, since misbranding may result in a food safety hazard. One example of misbranding that is also a food safety hazard is when allergens are present but undeclared on the label. When an establishment determines that misbranded products have entered commerce, it is to notify the District Office, as required by 9 CFR 418.2. Misbranding events may require relabeling; the establishment should consult with the FSIS Office of Policy and Program Development (OPPD) Labeling and Program Delivery Staff (LPDS) to determine how to correct or replace the inaccurate labels. Certain misbranded products may be eligible for donation. Misbranded and economically adulterated meat and<sup>1</sup>,<sup>2</sup> poultry products can be donated provided the label does not contain any undeclared ingredients of public health concern as described in FSIS Directive 7020.1, Verifying Donation Of Misbranded And Economically Adulterated Meat And Poultry Products To Non-Profit Organizations. Other Actions Each establishment should be proactive in response to any adulteration or misbranding event, evaluate how the affected products were adulterated or misbranded, why they were shipped undetected, and assess the HACCP system for any other vulnerability. For example, if a piece of plastic in a food product is determined to be from a single conveyor belt, the establishment should consider whether it is an isolated incident. FSIS believes the best practice would be to re-inspect all belts and reevaluate the preventive maintenance program and controls that failed to detect the faulty belt resulting in adulterated products. The establishment should consider replacing gaskets, belts, screens, and other loose items with components that are detectable (e.g., bright color, radiolucent). Increased lighting, employee training, and enhanced screening of raw material are some additional corrective actions that may produce a meaningful result. Any corrective action should prevent additional adulterated or misbranded products from being produced at the establishment. Diversion to pet food as a corrective action If an establishment determines that adulterated products are not logistically or practically eligible for rework to be made unadulterated, then the products are inedible and must be handled as inedible materials in accordance with FSIS regulatory requirements (9 CFR 325.11, 381.193). In some cases, inedible materials can be sent to a pet food manufacturer. However, because pet food production is under the jurisdiction of the FDA, the establishment is cautioned to check with the manufacturer or the FDA prior to sending the adulterated products to the pet food facility. Some types of adulteration are not eligible for pet food and are not permitted by FDA to be sent for pet food. If the products are not eligible for pet food, the remaining options are rendering or a landfill. Please note that rendering companies may not be willing to accept products adulterated with foreign material if the materials will damage the equipment. The establishment is encouraged to verify that the products will be accepted by the renderer.<sup>1</sup>,<sup>2</sup> Suggested Tips: Follow these tips when writing a customer complaint program: \u2022 Provide customers with a method to notify you: \u2022 Consider the impact of co-packing or products produced in multiple establishments \u2022 Provide multiple modes of communication: email, telephone, mail, etc. \u2022 Facilitate the substantiation of any complaint: \u2022 Pay to have a label or foreign material mailed to you \u2022 Ask questions to gather as much information as possible \u2022 Develop investigation SOPs \u2022 Identify establishment and FSIS personnel who need to be notified and provide the contact information in the document, so you don\u2019t have to look for it later: \u2022 District Office contact information is available on the Contact Us page of www.fsis.usda.gov \u2022 Inspection personnel office phone

numbers are available to the individual establishment \u2022 Evaluate the HACCP system and relevant programs; \u2022 Document findings and make them available to FSIS upon request; \u2022 Consider that the complaint may indicate a larger issue; \u2022 Be proactive. \u2013 Put procedures in place now to prevent adulteration", "23 Example Flow Diagram of a Customer Complaint", "24 References: REGULATIONS United States Department of Agriculture, Food Safety and Inspection Service. 2012. first version of the FSIS Guideline to Assist with the Donation of Eligible Meat & Poultry	
Products to Non-Profit Organizations. This guideline represents FSIS\u2019s current thinking on	

these topics and should be considered usable as of its issuance. This document is not regulatory. The contents of this document do not have the force and effect of law and are not meant to bind the public in any way. Purpose This guideline contains information to assist meat and poultry establishments and nonprofit organizations that donate and receive donated products comply with the Federal Meat Inspection Act (FMIA), the Poultry Products Inspection Act (PPIA), and FSIS regulations in 9 CFR Chapter III. This guideline includes information on: \u2022 Products eligible for donation; \u2022 Products ineligible for donation; \u2022 Shipping donated products; \u2022 Labeling donated products; \u2022 Donating products produced under inspection exemptions; \u2022 Donation recipient types; \u2022 Donating State-inspected products; \u2022 Donating \u201cexpired\u201d products; \u2022 Relabeling at non-profit organizations; and \u2022 Retail exemption at non-profit organizations. Reason for Issuing the Guideline FSIS developed this guideline to assist establishments and non-profit organizations that donate and receive donated meat and poultry products by addressing common food donation questions. FSIS has received several questions from meat and poultry establishments and non-profit organizations on this subject and has decided to address the major concerns associated with donation in this guideline. This guideline will be useful because it addresses issues that have been presented to FSIS related to food donation (e.g., products eligible for donation, labeling donated products, and donating products produced under exemption). This guideline will provide information that will help reduce food loss and waste and help battle food insecurity.", "5 How to Effectively Use the Guideline This guideline is organized to provide users with the current science and recommendations for topics related to the donation of meat and poultry products to nonprofit organizations. This guidance document includes recommendations for meat and poultry producers and non-profit organizations on how to donate and receive donated products in compliance with the FMIA, PPIA, and FSIS regulations in 9 CFR Chapter III. To use this guideline, FSIS recommends that readers use the navigation headings to move efficiently through the document sections of interest. Hyperlinks, where provided, will quickly take you to the correct place in the document electronically and are also provided to other complementary documents. How to Comment on the Guideline FSIS is seeking public comment on this guideline as part of its efforts to continuously assess and improve the effectiveness of policy documents. All interested persons may submit comments regarding any aspect of this document, including but not limited to content, readability, applicability, and accessibility. The comment period will be 60 days from publication of the Federal Register Notice and, as appropriate, the Agency may update this guideline in response to comments. Although FSIS may make changes to the guideline in response to comments, this document reflects current thinking, and FSIS encourages establishments producing products discussed in this document to review it and begin using it. Comments may be submitted by either of the following methods: \u2022 Federal eRulemaking Portal Online submission at regulations.gov. This website provides a way to type short comments directly into the comment field on the webpage or attach a file to submit lengthier comments. Follow the online instructions at that site to submit comments. \u2022 Mail, including CD-ROMs, etc.: Send to Docket Clerk, U.S. Department of Agriculture, Food Safety and Inspection Service, 1400 Independence Avenue SW, Mailstop 3758, Washington, DC 20250-3700. All items submitted by mail or electronic mail must include the Agency name, FSIS, and document title: FSIS Guideline to Assist with the Donation of Eligible Meat & Poultry Products to Non-Profit Organizations.

Comments received will be made available for public inspection and posted without change, including any personal information, to <http://www.regulations.gov>. Questions Regarding Topics in this Guideline If after reading this guideline you still have questions, FSIS recommends that users search the publicly posted Questions & Answers (Q&As) in the askFSIS database or submit questions through askFSIS. Documenting these questions helps FSIS improve and refine present and future versions of the guideline and associated issuances." "6 When submitting a question, use the Submit a Question tab, and enter the following information in the fields identified below as prescribed: Subject Field: FSIS Guideline to Assist with the Donation of Eligible Meat & Poultry Products to Non-Profit Organizations Question Field: Your question with as much detail as possible. Product Field: Select General Inspection Policy. Category Field: Select Donated Product from the drop-down menu. Policy Arena: Select Domestic (U.S.) Only from the drop-down menu. When all fields are complete, press Continue. FSIS Guideline to Assist with the Donation of Eligible Meat & Poultry Products to Non-Profit Organizations Background In the United States, food waste is estimated as constituting between 30-40 percent of the food supply. This figure, based on estimates from USDA\u2019s Economic Research Service of a 31 percent food loss at the retail and consumer levels, corresponds to approximately 133 billion pounds and \$161 billion worth of food in 2010. Wasted food is the single largest category of material placed in municipal landfills and represents nourishment that could have helped feed families in need. Additionally, water, energy, and labor used to produce wasted food could have been employed for other purposes. Effectively reducing food waste will require cooperation among federal, state, tribal and local governments, faith-based institutions, environmental organizations, communities, and the entire supply chain. In October 2018, the U.S. Department of Agriculture (USDA), the U.S. Environmental Protection Agency (EPA), and the U.S. Food and Drug Administration (FDA) launched the Winning on Reducing Food Waste Initiative in a formal agreement. As part of the initiative, the agencies affirmed their shared commitment to work towards the national goal of reducing food loss and waste by 50 percent by 2030. The agencies agreed to coordinate food loss and waste actions such as education and outreach, research, community investments, voluntary programs, public-private partnerships, tool development, technical assistance, event participation, and policy discussion on the impacts and importance of reducing food loss and waste. While there have been significant actions taken and commitments made through public-private partnerships to date, there is still much work to be done. See USDA\u2019s Winning on Reducing Food Waste page for more information on USDA\u2019s commitment to this cause. Meat and poultry businesses can be a critical component of reducing food loss and waste. FSIS encourages establishments to donate meat and poultry products to nonprofit organizations, when possible, to reduce food loss and waste." "7 Donation Flowchart This table represents the most common questions establishments face when deciding to donate meat or poultry products. More detailed information about each of these questions and answers is included in the following pages. Guidance for Donating Establishments \u2022 Products Eligible for Donation - Federally-Inspected and Passed Products Meat and poultry establishments may always donate federally-inspected meat and poultry products that are safe, wholesome, and not misbranded to non-profit organizations, such as charitable institutions, food banks, and government-supported facilities (e.g., correctional facilities, child welfare facilities, homes for senior populations, institutions for the physically or mentally ill, or similar qualifying institutions) (see 21 U.S.C.

673(a)(5)(A) and 21 U.S.C. 467b(a)(5)(A)). - Misbranded and Economically Adulterated Products Historically, safe and wholesome misbranded or economically adulterated meat and poultry products (further defined below) could be donated to non-profit organizations only after receiving temporary label approval from FSIS and marking each immediate container with a \u201cNot for Sale\u201d statement. However, in order to facilitate the donation of edible human food to non-profit organizations, FSIS has streamlined the donation procedures for certain misbranded and economically adulterated meat or poultry products. FSIS now allows official establishments to forego the temporary label", "8 approval and the marking of each immediate container with the \u201cNot for Sale\u201d statement for some products, if the FSIS inspection program personnel can verify that the Bill of Lading accompanying the products contains: 1. The quantity of the donated products; 2. A description of the donated products; 3. The reason products are diverted for donation (e.g., incorrect net weight); and 4. A statement that the products are \u201cNot for Sale.\u201d If the products are misbranded because they contain unlabeled ingredients of public health concern, the official establishment will have to take additional steps before donating. FSIS requires a temporary label approval from FSIS\u2019s Labeling and Program Delivery Staff (LPDS) (9 CFR 412.1(f)(1)), a \u201cNot For Sale\u201d statement on each immediate container of these products, along with identification of the ingredients. Ingredients of public health concern include the eight most common (\u201cThe Big 8\u201d) food allergens. \u201cThe Big 8\u201d allergens are: wheat, Crustacean shellfish (i.e., shrimp, crab, lobster), eggs, fish, peanuts, milk, tree nuts, and soybeans. Ingredients of public health concern also include ingredients that may cause food intolerance, such as sulfur-based preservatives (sulfites), lactose, Yellow 5 (tartrazine), gluten, and monosodium glutamate (MSG). The adverse reactions to these substances are caused by the ingredient itself or its chemical composition. Products are economically adulterated when any valuable constituent in whole or in part has been omitted or removed, when any less valuable substance has been substituted, when any substance is added or mixed, or when packaging misrepresents the weight or bulk making them appear to be of greater value (21 U.S.C. 601(m)(8) or 21 U.S.C. 453(g)(8)). In most cases of economic adulteration, a substance is added or intentionally substituted for the purpose of increasing the apparent value of the product. For example, a poultry carcass with added water that exceeds the maximum percentage of water that may be retained under 9 CFR part 441 would be economically adulterated, because the added water increases the product\u2019s net weight and makes it appear to be of greater value. FSIS personnel will follow the instructions found in FSIS Directive 7020.1 Verifying Donation of Misbranding and Economically Adulterated Meat and Poultry Products to Non-Profit Organizations or FSIS Directive 8410.1 Detention and Seizure when verifying donations of misbranded or economically-adulterated meat and poultry products to nonprofit organizations. - Products Intended for Export Meat and poultry producers may be permitted to donate certain products intended for export to domestic non-profit organizations if the products are safe and wholesome. FSIS requires a temporary label approval (9 CFR 412.1(f)(1)) for donated products originally intended for export unless the label bears no deviations from domestic requirements other than being labeled \u201cFor Export Only.\u201d If any language on the products\u2019 labeling is not translated into English, the translation will need to accompany", "9 the application for temporary approval in order to provide LPDS with adequate information. - Sample Products Meat and poultry producers may donate sample

products to non-profit organizations. Sample products are products that are made available for pre-market consumer testing, are available to the general public, and are not for sale. Because sample products are produced for general public consumption, they must be produced and labeled in accordance with the meat and poultry products inspection regulations. More information about sample products can be found in FSIS Directive 7000.2 Experimental and Sample Products Policy.

\u2022 Products Ineligible for Donation

Below are two ineligible product types that industry frequently requests information on donating. Additional products that are ineligible for donation are discussed in other sections of this guideline.

- Adulterated Products

An official establishment cannot dispose of adulterated products by donating them to a non-profit organization, except when products are found to only be economically adulterated (21 U.S.C. 601(m)(8) or 21 U.S.C. 453(g)(8)), as discussed above. Unwholesome, adulterated products may not be donated to non-profit organizations (21 U.S.C. 601(m)(3) or 21 U.S.C. 453(g)(3)).

- Experimental Products

Official establishments are not eligible to donate experimental products to non-profit organizations. Experimental products are new or existing products that introduce a new formulation or flavor. They are limited to research and development under the control of the producing official establishment. Because experimental products are not inspected, they may not enter commerce. More about experimental products can be found in FSIS Directive 7000.2 Experimental and Sample Products Policy.

\u2022 Shipping Donated Products

The donating establishment, the shipping firm, and the receiving non-profit organization all have a responsibility to maintain human food in an unadulterated state. More information on keeping products safe during transport can be found in the FSIS Safety and Security Guidelines for the Transportation and Distribution of Meat, Poultry, and Egg Products.

"10 \u2022 Labeling Donated Products - Incorrect Standards of Identity

An establishment can donate products that do not meet the standard of identity listed on the label (e.g., beef stew formulated with less than 25% beef) without having to contact LPDS, but the reason the product doesn't meet the standard of identity must be mentioned in the bill of lading.

- Statement of Limited Use/\u2022 Distribution

An official establishment can donate products bearing a statement of limited use (e.g., \u201cfor further processing,\u201d \u201cfor institutional use only\u201d) to a non-profit organization. A statement of limited distribution (i.e., \u201cNot for Sale\u201d or \u201cFor Charity Only\u201d) is not required on unadulterated, properly labeled meat or poultry products that are being donated to non-profit organizations. However, FSIS recommends adding a statement of limited distribution to the products\u2019 labeling to avoid further distribution of products by non-profit organizations. Such a statement may be generically-approved and added to the products per 9 CFR part 412. This statement can be applied to the immediate containers, shipping container, or the bill of lading accompanying the donated products to the non-profit organization. The statement \u201cNot for Sale\u201d is required on the labeling of economically-adulterated or misbranded products that have been detained by FSIS and disposed of by donation to non-profit organizations, per 21 U.S.C. 673 (a)(5)(A)(ii) and 21 U.S.C. 467(a)(5)(A)(iii).

\u2022 Donating Products Produced Under Inspection Exemptions - Can I Donate Meat Products Slaughtered and/\u2022 or Processed under an Exemption to Federal Inspection (see 9 CFR 303.1)?

Exemption Type Eligible to Donate? Personal Use No Custom Slaughter and Custom Processing No Retail Store Yes Restaurant Yes Caterer Yes Restaurant Central Kitchen Yes", "11 Further explanation of each meat inspection exemption type and its eligibility to be donated is found in

the FSIS Guideline for Determining Whether a Livestock Slaughter or Processing Firm is Exempt from the Inspection Requirements of the Federal Meat Inspection Act. - Can I Donate Poultry Products Slaughtered and\or Processed under an Exemption to Federal Inspection (See 9 CFR 381.10)? Exemption Type Eligible to Donate? Personal Use No Custom Slaughter\Processing No Producer\Grower 1,000 Bird Limit Yes, intrastate Producer\Grower 20,000 Bird Limit Yes, intrastate Producer\Grower or Other Person (PGOP) Yes, intrastate Small Enterprise Yes, intrastate Retail Dealer Yes Retail Store Yes Further explanation of each poultry inspection exemption type and its eligibility to be donated is found in the Guidance for Determining Whether a Poultry Slaughter or Processing Operation is Exempt from Inspection Requirements of the Poultry Products Inspection Act. The guideline does not address exemption requirements where state laws may be different from those in the Poultry Products Inspection Act (PPIA) and FSIS\USDA regulations. States may have additional requirements and regulations, beyond FSIS\u2019s requirements, for donating products produced under the Producer\Grower, PGOP, and Small Enterprise exemptions. \u2022 Donation Recipients - Donation to Schools for Human Consumption An establishment can donate meat and poultry products to a school if the final products are fully labeled and wholesome. - Non-Profit Fundraiser An establishment can donate products to a non-profit fundraiser to be sold if the products are inspected and passed by FSIS.", "12 \u2022 Donating State-Inspected Products Under the Cooperative Interstate Shipment (CIS) program, certain state-inspected establishments can operate the same as federally-inspected facilities. Under specific conditions, these establishments can ship their products in interstate and international commerce. Therefore, products produced under the CIS program are eligible for donation. If a state-inspected establishment has not produced the product under the CIS program, it is limited to donating product within its own state borders according to state laws. \u2022 Donating \u201cExpired\u201d Products Producers can donate products past the \u201cbest if used by\u201d or \u201ccell by\u201d date. Manufacturers provide dating to help consumers and retailers decide when food is of best quality. Except for infant formula, product dates are not an indicator of products\u2019 safety and are not required by Federal law. The quality of perishable products may deteriorate after the date passes, but the products should still be wholesome if not exhibiting signs of spoilage. Spoiled foods will develop an off odor, flavor or texture due to naturally occurring spoilage bacteria, making the food not wholesome. If a food has developed such spoilage characteristics, it should not be eaten. FSIS recommends that food banks, other charitable organizations, and consumers evaluate the quality of the products before their distribution and consumption to determine if there are noticeable changes in wholesomeness. More information on product dating can be found on FSIS\u2019s Food Product Dating page. Guidance for Organizations Receiving Donated Products \u2022 Relabeling (ID Services) Non-profit organizations that repackaging products need to ensure that the products they receive and distribute are properly labeled. This is especially important with raw products that may appear to be fully cooked (e.g., raw, breaded poultry products) because some consumers might not know how to properly handle and cook the product. Ensuring proper labeling can prevent inadequate cooking by consumers, reducing the risk of foodborne illness. A non-profit organization, such as a food bank, can receive federally inspected and passed products in bulk, break bulk, repackaging, label, and distribute them to customers in need under the retail exemption to federal inspection (see 9 CFR 303.1(d) and 381.10(d)). If the non-profit organization receives state-inspected products,

they may be distributed within the state only. The non-profit organization must ensure that the repackaged products meet all FSIS labeling requirements that apply at retail: the name of the product, the name and address of the manufacturer, packer or distributor of the product (which can be the food bank), a list of ingredients if the product is made from two or more ingredients, a special handling statements (like Keep Refrigerated) if", "13 product is perishable, nutrition information (unless an exemption applies, such as that the product will not be sold) and safe-handling instructions (if not ready-to-eat) (see 9 CFR 317.2 and 381 Subpart N). In accordance with 9 CFR 303.1(f) and 9 CFR 381.10(a)(1), the adulteration and misbranding provisions of the FMIA and PPIA apply to articles that are exempted from inspection. For a check list of required label features, please visit FSIS\u2019s \u201cLabel Submission Checklist\u201d page, and for more information on labeling requirements, please visit FSIS\u2019s Basics of Labeling page. Product exempt from FSIS inspection must not bear the FSIS inspection legend. \u2022 Retail Exemption- Preparation of Meat and Poultry Products at Non-Profit Organizations As mentioned above, non-profit organizations are eligible to prepare meat and poultry products under the retail exemption. Retail exempt products may be donated as retailers are required to use federally or state-inspected source materials when preparing any meat or poultry products under the retail exemption found in 9 CFR 303.1(d) and 9 CFR 381.10(d). Retailers are subject to the licensing requirements of state or local (county, city) authorities, while producing products under the retail exemption, without FSIS inspection. The adulteration and misbranding provisions of the FMIA and PPIA apply to products which are exempted from inspection.", "14 http://askfsis.custhelp.com/ USDA FSIS www.fsis.usda.gov 2020"]}, {"file\_name": "FSIS\_GD\_2020\_0017", "title": "Expansion of the Use of the Term \u201cHealthy\u201d", "num": "FSIS-GD-2020-0017", "id": "d419f7e2ab8524c4e23de4b8c19f4f411dd29423a2c9e7514652326a4d6f1fd9", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/media\_file/2020-07/2019-0008.pdf", "type": "pdf", "n\_pages": 3, "word\_count": 3078, "text\_by\_page": ["15759 Federal Register\\Vol. 85, No. 54\\Thursday, March 19, 2020\\Notices information is estimated to average 15 minutes per response. Reduction Act of 1995, Public Law 104\ufe0f. Comments are required regarding; whether the collection of information is necessary for the proper performance of the functions of the agency, including whether the information will have practical utility; the accuracy of the agency\u2019s estimate of burden including the validity of the methodology and assumptions used; ways to enhance the quality, utility and clarity of the information to be collected; and ways to minimize the burden of the collection of information on those who are to respond, including through the use of appropriate automated, electronic, mechanical, or other technological collection techniques or other forms of information technology. Comments regarding this information collection received by April 20, 2020 will be considered. Written comments and recommendations for the proposed information collection should be submitted within 30 days of the publication of this notice on the following website [www.reginfo.gov\](http://www.reginfo.gov/) public\do\PRAMain. Find this particular information collection by selecting \u2018\ufe0fCurrently under 30-day Review\ufe0fOpen for Public Comments\u2019\ufe0f or by using the search function. An agency may not conduct or sponsor a collection of information unless the collection of information displays a currently valid OMB control number and the agency informs potential persons who are to respond to the collection of information that such persons are not required to respond to the collection of information unless it displays a currently valid OMB control number. Farm Service Agency Title: Wildfires and Hurricanes Indemnity Program Pluses (WHIP+). OMB Control Number: 0560\ufe0f0294. Summary of Collection: The Additional Supplemental Appropriations for Disaster Relief Act, 2019 (Disaster Relief Act; Pub. L. 116\ufe0f 20) authorized \$3 billion in assistance for losses to crops, trees, bushes, and vines due to 2018 and 2019 hurricanes, floods, tornadoes, typhoons, volcanic activity, snowstorms, and wildfires. The Disaster Relief Act requires all participants who receive WHIP+ payments to purchase crop insurance or NAP coverage for the applicable crop years for which they are requesting assistance. Need and Use of the Information: The information submitted by respondents on the various forms will be used by FSA to determine eligibility and distribute payments to eligible producers under WHIP+. Failure to solicit application will result in failure to provide payments to eligible producers as intended by the Disaster Relief Act.

Description of Respondents: Farms. Number of Respondents: 26,592. Frequency of Responses: Reporting; Other (one-time). Total Burden Hours: 18,405. Ruth Brown, Departmental Information Collection Clearance Officer. [FR Doc. 2020\ufe0f05736 Filed 3\ufe0f2018\ufe0f201320; 8:45 am] BILLING CODE 3410\ufe0f021305\ufe0f0213P DEPARTMENT OF AGRICULTURE Food Safety and Inspection Service [Docket No. FSIS\u2019\ufe0f02130008] Expansion of Use of the Term \u2018\ufe0f2018Healthy\u2019\ufe0f2019 AGENCY: Food Safety and Inspection Service, USDA. ACTION: Notice and request for comments. SUMMARY: The Food Safety and Inspection Service (FSIS) is announcing that it will allow establishments to use the implied nutrient content claim \u2018\ufe0f2018healthy\u2019\ufe0f2019 on their labels which: (1) Are not low in total fat, but have a fat profile makeup of predominantly mono and polyunsaturated fats; or (2) contain at least ten percent of the Daily Value (DV) per reference amount customarily consumed (RACC) of potassium or vitamin D. FSIS is making this announcement to maintain consistent requirements for food labels by allowing the same uses of the claim \u2018\ufe0f2018healthy\u2019\ufe0f2019 for meat and poultry products as are currently allowed for food products under the Food and Drug Administration\u2019s (FDA\u2019s) jurisdiction. DATES: This notice is applicable March 19, 2020. Submit comments on or before

May 18, 2020. ADDRESSES: FSIS invites interested persons to submit comments on this notice. Comments may be submitted by one of the following methods: Federal eRulemaking Portal: This website provides the ability to type short comments directly into the comment field on this web page or attach a file for lengthier comments. Go to <http://www.regulations.gov>. Follow the on-line instructions at that site for submitting comments. Mail, including CD\u2013ROMs, etc.: Send to Docket Clerk, U.S. Department of Agriculture, Food Safety and Inspection Service, 1400 Independence Avenue SW, Mailstop 3758, Room 6065, Washington, DC 20250\u2013700. Hand- or Courier-Delivered Items: Deliver to 1400 Independence Avenue SW, Room 6065, Washington, DC 20250\u2013700. Instructions: All items submitted by mail or electronic mail must include the Agency name and docket number FSIS\u20132019\u20130008. Written comments received in response to this docket will be made available for public inspection and posted without change, including any personal information, to <http://www.regulations.gov>. SUPPLEMENTARY INFORMATION: Background FSIS is the public health regulatory agency in the USDA that is responsible for ensuring that the nation's commercial supply of meat and poultry products is safe, wholesome, and accurately labeled and packaged. Under the Federal Meat Inspection Act (FMIA) (21 U.S.C. 601\u2013695, at 607) and the Poultry Products Inspection Act (PPIA) (21 U.S.C. 451\u2013470, at 457), the labels of meat and poultry products must be approved by the Secretary of Agriculture, who has delegated this authority to FSIS, before these products can enter commerce. The FMIA and PPIA also prohibit the sale or offer for sale by any person, firm, or corporation of any article in commerce under any name or other marking or labeling that is false or misleading (21 U.S.C. 601(n) and 607(d); 21 U.S.C. 453(h) and 457(c)). FSIS Regulations for \u2018\u2018Healthy\u2019\u2019\u2019 Claims FSIS regulations (9 CFR 317.363(b) and 381.463(b)) define the parameters for the use of the implied nutrient content claim \u2018\u2018healthy\u2019\u2019 or any other derivative of the term \u2018\u2018health\u2019\u2019 and similar terms on meat and poultry product labeling. The definitions establish specific criteria for nutrients to limit in the diet, such as total fat, saturated fat, cholesterol, and sodium; and requirements for nutrients to encourage in the diet, including vitamin A, vitamin C, calcium, iron, protein, and fiber. On May 10, 1994, FSIS published a final rule defining the term \u2018\u2018healthy\u2019\u2019\u2019 that included new standards for sodium (59 FR 24220). FSIS created initial \u2018\u2018first-tier\u2019\u2019\u2019 sodium standards, and \u2018\u2018second-tier\u2019\u2019\u2019 sodium standards that would become more rigorous after a 24-month time period. After extending the first-tier sodium

standards in the Federal Register (63 FR 7279, 64 FR 72490, and 68 FR 460), FSIS decided, in 2006, to indefinitely defer to the first- tier sodium standards (71 FR 1683). Consequently, FSIS continues to apply the original (first-tier) levels of sodium established in the 1994 regulation when approving labels for \u2018\u2018healthy.\u2019\u2019 Recent Changes to Regulations and Policy In December 2015, USDA and the U.S. Department of Health and Human Services (HHS) published the 2015\u2013 2020 Dietary Guidelines for Americans.<sup>1</sup> The Dietary Guidelines were designed for professionals to help all individuals consume a healthy and nutritionally- adequate diet. Specific recommendations in the Dietary Guidelines have evolved over time, as nutrition science has advanced. For example, scientific understanding and nutrition guidance has shifted from recommending diets low in total fat to recommending keeping overall fat intake within the age-appropriate acceptable macronutrient distribution ranges (AMDR), and instead prioritizing replacing saturated fats with polyunsaturated and monounsaturated fats and keeping trans fat intake as low as possible. On May 27, 2016, FDA issued two final rules updating the Nutrition Facts label and serving size information for packaged foods (81 FR 33742 and 81 FR 34000). The above-mentioned 2015\u2013 2020 Dietary Guidelines for Americans served as the scientific basis for these two FDA final rules that included changes in the individual nutrients that must be declared on the Nutrition Facts label and changes to the DV of other individual nutrients. The changes reflected the most recent nutrition and public health research and recent dietary recommendations from expert groups. These rules also improved the presentation of nutrition information on the Nutrition Facts label to help consumers make more informed choices and maintain healthy dietary practices.

Consistent with FDA\u2019s final rules, FSIS has proposed to change its nutrition labeling regulations (82 FR 6732). In November 2016, FSIS published a Federal Register notice allowing FSIS products to voluntarily adopt the FDA Nutrition Facts label format (81 FR 80631). The notice explained that at least one label sketch with the FDA nutrition format must be submitted to FSIS before that format could be generically approved for other products. On September 28, 2016, FDA announced in the Federal Register that it was requesting comments on the use of the term \u2018\u2018healthy.\u2019\u2019 in the labeling of human food products (81 FR 66562). According to this Federal Register notice, FDA published the notice in accordance with the FDA Foods and Veterinary Medicine Program\u2019s 2016\u2013 2025 Strategic Plan and in response to a citizen petition requesting that FDA update the nutrient content claim regulations to be consistent with current Federal dietary guidance. Specifically, FDA\u2019s notice stated that the petitioner requested that the Agency amend the regulation defining \u2018\u2018healthy.\u2019\u2019 as it relates to total fat intake and to emphasize whole food and dietary patterns rather than specific nutrients. Additionally, in the same Federal Register publication, FDA announced the availability of a guidance document for industry entitled \u2018\u2018Use of the Term \u2018Healthy\u2019 in the Labeling of Human Food Products: Guidance for Industry\u2019\u2019 (81 FR 66527). According to FDA, the science supporting public health recommendations for the intake of various nutrients had evolved, as evidenced in the 2015\u2013 2020 Dietary Guidelines. FDA also announced the Agency\u2019s intention to temporarily exercise enforcement discretion with respect to some of the criteria for bearing the implied nutrient content claim \u2018\u2018healthy.\u2019\u2019 until 21 CFR 101.65(d)(2) is amended through rulemaking. In the Federal Register notice, FDA explained that it intended to exercise enforcement discretion with respect to the current requirement that any

food bearing the nutrient content claim \u2018\u2018healthy\u2019\u2019 meet the low-fat requirement provided that: (1) The amounts of mono- and polyunsaturated fats are declared on the label; and (2) the amounts of mono- and polyunsaturated fats declared constitute most of the fat content. FDA also stated, in the notice, that it intends to exercise enforcement discretion with respect to the current requirement that any food bearing the nutrient content claim \u2018\u2018healthy\u2019\u2019 contain at least ten percent of the DV per RACC of vitamin A, vitamin C, calcium, iron, protein, or fiber, if the food instead contains at least ten percent of the DV per RACC of potassium or vitamin D. FDA\u2019s guidance document is available at <https://www.fda.gov/downloads/Food/GuidanceRegulation/GuidanceDocumentsRegulatoryInformation/UCM521692.pdf>. FSIS\u2019s Policy To maintain consistent requirements for food labels, FSIS has used its enforcement discretion to allow the same uses of the claim \u2018\u2018healthy\u2019\u2019 for meat and poultry products as are VerDate Sep<11>2014 17:05 Mar 18, 2020 Jkt 250001 PO 00000 Frm 00003 Fmt 4703 Sfmt 4703 E:\\FR\\FM\\19MRN1.SGM 19MRN1 jbell on DSKJLSW7X2PROD with NOTICES", "15761 Federal Register\\Vol. 85, No. 54\\Thursday, March 19, 2020\\Notices 2FSIS\u2019s Label Submission and Approval System (LSAS) is a web-based software application that integrates and implements an electronic label application process for establishments to submit label applications to FSIS. allowed for food products under FDA jurisdiction under FDA\u2019s 2016 guidance. There are few labels that qualify for the \u2018\u2018healthy\u2019\u2019 claim under the allowances in this notice that wouldn\u2019t qualify otherwise. According to FSIS\u2019s Label Submission and Approval System (LSAS)2data, the types of products utilizing FDA\u2019s guidance for the claim \u2018\u2018healthy\u2019\u2019 are mostly products that meet the definition of meal-type in 317.313(l)/381.413(l). Egg product labels are not affected by this policy because FSIS inspected egg products are required by regulation to use the FDA nutrition requirements in 21 CFR part 101 in compliance with 9 CFR 590.411(e)\u2014as such, egg product labeling follows the FDA nutrition panel and the FDA enforcement discretion even though FSIS\u2019s Labeling and Program Delivery Staff (LPDS) reviews and approves FSIS inspected egg product label applications. Because FSIS has received multiple questions from industry about our policy, FSIS is announcing in this Federal Register notice that it will continue to recognize FDA\u2019s 2016 guidance to alleviate consumer confusion and promote uniformity in the marketplace. Specifically, FSIS has allowed and will continue to allow the implied nutrient content claim \u2018\u2018healthy\u2019\u2019 on foods that have a fat profile of predominantly mono and polyunsaturated fats (i.e. sum of monounsaturated fats and polyunsaturated fats are greater than the total saturated fat content of food), but do not meet the regulatory definition of \u2018\u2018low fat,\u2019\u2019 as specified in 9 CFR 317.363(b)(1)/381.463(b)(1) or that contain at least ten percent of the DV per RACC of potassium or vitamin D as one of the options in 9 CFR 317.363(b)(4) and 381.463(b)(4), provided the remaining criteria for healthy in 9 CFR 317.363 and 381.463 have been met. FSIS\u2019s LPDS has reviewed many proposed labels referencing FDA\u2019s \u2018\u2018healthy\u2019\u2019 notice, and most have contained errors and needed correction. If a company wishes to use FDA\u2019s \u2018\u2018healthy\u2019\u2019 claim, they will first need to submit at least one label sketch to LPDS for approval. A corporation\u2019s parent-company only needs to submit one label application for a product produced in multiple establishments that are owned by the corporation. Subsequent similar

labels for other products that use FDA\u2019s \u2018\u2018healthy\u2019\u2019 claim can be generically approved. Submitting one label and receiving approval helps ensure that the rest of the labels are in compliance with FDA and FSIS regulations. Labels using the modified \u2018\u2018healthy\u2019\u2019 claim must be submitted to LPDS in the new FDA nutrition panel format. FSIS will continue to allow the use of implied nutrient content claim \u2018\u2018healthy\u2019\u2019 on foods that have a fat profile of predominantly mono and polyunsaturated fats (i.e., sum of monounsaturated fats and polyunsaturated fats are greater than the total saturated fat content of food), but do not meet the regulatory definition of \u2018\u2018low fat,\u2019\u2019 as specified in 9 CFR 317.363(b)(1) and 381.463(b)(1) or that contain at least ten percent of the DV per RACC of potassium or vitamin D as one of the options in 9 CFR 317.363(b)(4) and 381.463(b)(4), provided the remaining criteria for healthy in 9 CFR 317.363 and 381.463 have been met until FSIS\u2019s \u2018\u2018healthy\u2019\u2019 regulations (9 CFR 317.363(b) and 381.463(b)) are amended through rulemaking. FSIS will continue to coordinate with FDA on any changes to these regulations. Additional Public Notification Public awareness of all segments of rulemaking and policy development is important. Consequently, FSIS will announce this Federal Register publication on-line through the FSIS web page located at: <http://www.fsis.usda.gov/federal-register>. FSIS will also announce and provide a link to it through the FSIS Constituent Update, which is used to provide information regarding FSIS policies, procedures, regulations, Federal Register notices, FSIS public meetings, and other types of information that could affect or would be of interest to our constituents and stakeholders. The Constituent Update is available on the FSIS web page. Through the web page, FSIS is able to provide information to a much broader, more diverse audience. In addition, FSIS offers an email subscription service which provides automatic and customized access to selected food safety news and information. This service is available at: <http://www.fsis.usda.gov/subscribe>. Options range from recalls to export information, regulations, directives, and notices. Customers can add or delete subscriptions themselves and have the option to password protect their accounts.

Congressional Review Act Pursuant to the Congressional Review Act at 5 U.S.C. 801 et seq., the Office of Information and Regulatory Affairs has determined that this notice is not a \u2018major rule,\u2019 as defined by 5 U.S.C. 804(2). USDA Nondiscrimination Statement No agency, officer, or employee of the USDA shall, on the grounds of race, color, national origin, religion, sex, gender identity, sexual orientation, disability, age, marital status, family/\u00b7 parental status, income derived from a public assistance program, or political beliefs, exclude from participation in, deny the benefits of, or subject to discrimination, any person in the United States under any program or activity conducted by the USDA. How To File a Complaint of Discrimination To file a complaint of discrimination, complete the USDA Program Discrimination Complaint Form, which may be accessed online at: [http://www.ocio.usda.gov/sites/default/files/docs/2012/Complain\\_combined\\_6\\_8\\_12.pdf](http://www.ocio.usda.gov/sites/default/files/docs/2012/Complain_combined_6_8_12.pdf), or write a letter signed by you or your authorized representative. Send your completed complaint form or letter to USDA by mail, fax, or email: Mail: U.S. Department of Agriculture, Director, Office of Adjudication, 1400 Independence Avenue SW, Washington, DC 20250\u20139410. Fax: (202) 690\u20137442. Email: [program.intake@usda.gov](mailto:program.intake@usda.gov). Persons with disabilities who require alternative means for communication (Braille, large print, audiotape, etc.) should contact USDA\u2019s TARGET Center at (202) 720\u20132600 (voice and TDD). ACTION: Notice of Solicitation of Applications; Amendment. VerDate Sep<11>2014 17:05 Mar 18, 2020 Jkt 250001 PO 00000 Frm 00004 Fmt 4703 Sfmt 4703 E:\\\\FR\\\\FM\\\\19MRN1.SGM 19MRN1 jbell on DSKJLSW7X2PROD with NOTICES"]}, {"file\_name": "FSIS\_GD\_2021\_0001", "title": "HACCP Model for the New Swine Inspection System (pork slaughter)", "num": "FSIS-GD-2021-0001", "id": "1035b53f451d9bbf7c3b2b5f71740ad2a8a8741d4b894ae8d790325c3a174a3f", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/media\_file/2021-06/HACCP-Model-New-Swine-Inspection-System-2021-0001.pdf", "type": "pdf", "n\_pages": 20, "word\_count": 6182, "text\_by\_page": ["Page 1 of 20 A Generic HACCP Model for New Swine Inspection System (NSIS) The United States Department of Agriculture (USDA) published the Pathogen Reduction\\Hazard Analysis Critical Control Point (HACCP) Systems Final Rule in July 1996. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to address safety hazards reasonably likely to occur in their production process. Therefore, this HACCP model\\u2019s focus, and the focus of the other HACCP models, is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic model for each food processing category defined in the regulation (9 CFR 417.2(b)(1)). The guidebook and the generic models have been updated since their initial publication to be consistent with current science and policy. FSIS recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used \\u201cas is\\u201d. FSIS recommends that establishments tailor the model(s) to fit the establishment\\u2019s operation. Establishments that slaughter market hogs may choose to operate under NSIS. Market hog slaughter establishments that do not choose to operate under the NSIS may operate under the traditional inspection system. FSIS has published a generic HACCP model for Traditional Swine Slaughter. The NSIS model\\u2019s critical control points (CCPs) do not necessarily apply to all NSIS operations. Products or operations may require fewer or more CCPs depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The food safety critical limits selected must come from scientific documents or other reliable sources to meet regulatory validation requirements. This model includes references for guidance on the selection of critical limits. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis are HACCP records (CFR 417.5(a)). Ensure you maintain the

documents produced while developing a HACCP plan. For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage.", "Page 2 of 20 EXAMPLE PRODUCT DESCRIPTION1 Process \ Product Name: New Swine Inspection System (NSIS) Market Hog Slaughter and Variety Meats Process \ Product name NSIS Market Hog Slaughter and Variety Meats (carcasses, variety meats (offal) and head meat) Important product characteristics (Aw, pH, Preservatives, etc.) Not Applicable Intended use2 For further processing at this facility or another establishment or Intended for cooking by end consumer Packaging (durability and storage conditions) Vacuum-packaged, bagged, boxed or in combos (catch weights) Shelf life and at what temperature Carcasses: 7 days when stored at less than 40\u2109 Variety Meats: 15 days at less than 40\u2109, Frozen \u2013 180 Days at less than 10\u2109 Where it will be sold (specify intended consumers, especially at-risk populations3) Carcasses and variety meats are either further processed inhouse or sold direct to another establishment or to household consumers through retail outlets or distributed to hotels, restaurants, and institutions (HRI). Labeling instructions Product name, inspection legend and establishment number, handling statement, net weight statement, address line, nutrition facts, and safe handling instructions. What special distribution controls are required? Keep refrigerated < 40\u2109 or frozen < 10\u2109 DATE: APPROVED BY: 1 Prior to developing the HACCP plan please read the FSIS Guidebook for the Preparation of HACCP Plans for detailed descriptions of the worksheets and hazard analysis. The FSIS Guidebook for the Preparation of HACCP Plans and the NSIS generic HACCP model are intended for establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP model is for demonstration purposes only. The model does not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. 2 The intended use or consumer of the product must be identified in accordance with 9 CFR 417.2(a)(2). Identifying the product\u2019s intended use in the product description is one way to meet the regulatory requirements specific to 417.2(a)(2). 3 At-risk populations include young children, the elderly and immunocompromised persons.", "Page 3 of 20 EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING MATERIAL4 Process \ Product Name: NSIS Market Hog Slaughter and Variety Meats Meat and meat by-products Live hogs Non-meat food ingredients None Antimicrobials5 or processing aids6 Scald agents, organic acid Packaging material Foam bone protectors, cardboard boxes and combos, selfadhesive labels, plastic vacuum bags, plastic combo bin and box liners. Restricted ingredients or allergens None Other None DATE: APPROVED BY: 4 List all meat, non-meat ingredients, restricted ingredients (for example, nitrites), processing aids, packaging material used in production of this product. This is important to help identify any special ingredients or processes to address in the HACCP plan. 5 FSIS and the Food and Drug Administration (FDA) have a memorandum of understanding (MOU) that establishes the working relationship followed when responding to notifications for the use of food additives (including ingredients) intended for use in the production of FSIS regulated products. FSIS determines the suitability of the use of food ingredients used in the production of meat, poultry, and egg products. FSIS consults, as necessary, with FDA on the requirements under the Federal Food, Drug & Cosmetic Act and its implementing regulations. See FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat Poultry and Egg Products for the list of suitable ingredients. 6 There are many different

organic acids (for example, lactic acid, acetic acid). Establishments will need to research the various organic acids and select the antimicrobial intervention best suited for their unique circumstances and validate its effectiveness. Antimicrobial agents are listed in FSIS Directive 7120.1 Safe and Suitable Ingredients used in the Production of Meat, Poultry, and Egg Products.", "Page 4 of 20 EXAMPLE PROCESS FLOW DIAGRAM7 Process \ Product Name: NSIS Market Hog Slaughter and Variety Meats 17. Returned Product8 12. Variety Meats (offal) Feces and Ingesta Verification CCP 3 and Organic Acid Spray CCP 4.9 DATE: APPROVED BY: 7 This is an example flow diagram. Establishments\u2019 flow diagrams for the same product may be different. Establishments determine which steps are included in their process. The steps must represent all relevant hazards in the hazard analysis. 8 The Returned Product step (16) is shown as not connected to another process step. Returned product may re-enter the production system at different process steps depending on condition or food safety concerns. Returned product may be relabeled, re-processed, discarded, etc. 9 This model demonstrates the use of a CCP to ensure carcasses, heads and variety meats (offal) intended for human consumption are free of visible feces and ingestra. 9 CFR 310.18(a) states: \u201cCarcasses, organs, and other parts shall be handled in a sanitary manner to prevent contamination with fecal material, urine, bile, hair, dirt, or foreign matter\u201d. 5. Cold storage \ transfer to Fabrication HACCP plan or Shipping", "Page 5 of 20 EXAMPLE NSIS MARKET HOG SLAUGHTER AND VARIETY MEATS HAZARD ANALYSIS10 10 See FSIS Compliance Guideline for Controlling Salmonella in Market Hogs, FSIS Compliance Guideline for the Prevention and Control of Trichinella and Other Parasitic Hazards in Pork and Products Containing Pork, and FSIS Compliance Guide: Modernization of Swine Inspection \u2013 Developing Microbiological Sampling programs in Swine Slaughter Establishments for suggested slaughter best practices and a list of scientific and technical references. 11 Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P). Biological hazards are living organisms. Chemical hazards may be naturally occurring in foods, used, or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification. 12 Place the justification for your decision in column 4. Include control measures in column 4 for hazards not reasonably likely to occur and place them in column 5 for hazards reasonably likely to occur. If a hazard is reasonable likely to occur, then a CCP must be addressed at this step or a later step. See FSIS Meat and Poultry Hazards and Controls Guide for a list of frequently used controls. 13 Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced article must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS

program, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan.<sup>14</sup> Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5).<sup>15</sup> To determine a CCP, see Guidebook for the Preparation of HACCP Plans for a CCP decision tree. Use the tool to evaluate the areas of control (column 5) to determine the best CCP to control, reduce, or eliminate a hazard. Column 1 Column 2 Column 3 Column 4 Column 5 Column 6 Ingredient \ Process Step Potential Hazards (Introduced or Controlled) at This Step<sup>11</sup> Is the Potential Food Safety Hazard Reasonably Likely to Occur<sup>12</sup> (RLTO) (Yes or No) Justification \ Basis for Decision<sup>13</sup> If yes in Column 3 (hazard RLTO), What Control Measures Can Be Applied to Prevent, Eliminate, or Reduce the Hazard to Acceptable Levels?<sup>14</sup> Is this Step a Critical Control Point (CCP)?<sup>15</sup>,"Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 6 of 20<sup>16</sup> See FSIS Compliance Guideline for Controlling Salmonella in Market Hogs, FSIS Compliance Guideline for the Prevention and Control of Trichinella and Other Parasitic Hazards in Pork and Products Containing Pork for options used to prevent the control of Trichinella in pork and pork products. 1. Live Hog Receiving \ Live Hog Sorting B: Live animals showing physical signs of central nervous system (CNS) disease, pyrexia, or moribund conditions. Pathogens (Salmonella) Trichinella<sup>16</sup> Yes Yes No Market hogs may exhibit physical signs of CNS disease, pyrexia, or moribund conditions. Well documented that Salmonella are known to be present in digestive tracts swine. Acquire market hogs from herds with a Trichinæ Certification Program. Therefore, Trichinella is a hazard not reasonably likely to occur and treatment of such products for the destruction of Trichinæ is not necessary. CCP 1 Live Hog Sorting Sorters follow written Live Hog Sorting Standard Operating Procedure (SOP). Sorting procedures to remove hogs exhibiting conditions described in 9 CFR 309.19 prior to FSIS ante-mortem inspection Controlled at subsequent CCP 3 Feces and Ingesta Verification, and CCP 4 Organic Acid Spray Maintain adequate sanitation in holding pens, part of Good Manufacturing Practices (GMPs). CCP 1 No C: Drug residues No Low risk per FSIS Residue Monitoring Program, Compliance Guide for Residue Prevention. Residue certifications for live animals. Written Drug Residue Control SOP.", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 7 of 20<sup>17</sup> This Foreign Material SOP (prerequisite program) should have details on how this procedure is preventing the hazard from occurring (such as metal prevention controls) as well as the on-going verification

procedures. These controls should be evident within the written document upon review. The Foreign Material SOP and plant data related to ongoing verification activities then become part of recordkeeping and historic data. 18 Note: this \u201chistorical data\u201d must be supported with evidence from the establishment through the establishment\u2019s history or validation data with reference to the actual SOP or prerequisite program. When historical data is not available (for example, a HACCP plan for a new process or product), then system design must be supported by other documentary evidence, such as the FSIS Meat and Poultry Hazards and Controls Guide which states \u201cvisual examination of carcass for foreign material during slaughter\u201d is a frequently used control for foreign material hazards in swine slaughter. 19 The criteria used to determine when the live wash will be used should be clearly established in a prerequisite program. P: Foreign material \u2225 metal (needles, buckshot, bullets, hardware in intestinal tract) No Recorded historic data from written Foreign Material Standard Operating Procedure17 indicates low likelihood at this establishment and from suppliers.18 1a. Live Wash for Heavy Contamination19 (Optional) B: Pathogens (Salmonella) Yes Skin and hair from swine are a significant source of contaminants in slaughter operations. Controlled at subsequent CCP 3 Feces and Ingesta Verification, and CCP 4 Organic acid spray. Written Optional Wash SOP with conditions for use of optional wash (processing conditions, suppliers, customer specifications, etc.); wash parameters to decrease pathogens and prevent cross-contamination and ensure humane handling of swine. Select and examine 12 carcasses and 20 pounds of head meat, cheek meat, weasand meat and offal. Observe all surfaces of each split carcass before the FSIS inspection station. Observe all sides of each piece of head meat, cheek meat, weasand meat and offal at packaging. Once every three hours of production. QA Tech designee Contaminants are knife trimmed. Contaminated carcasses may be railed out for trimming.31 The production supervisor will per 9 CFR 417.3(a): 1. Hold all product produced after the last acceptable check until appropriate disposition taken (no product injurious to health will enter commerce); 2. Determine and eliminate the cause of the deviation; 3. Bring the CCP under control; and 4. Take measures to prevent recurrence. A member of management will ensure that corrective actions are completed. Once per day a QA Manager will directly observe the monitoring of carcasses, head meat, cheek meat, weasand meat and offal. QA Manager will conduct a daily record review. Feces and Ingesta Verification Form32 HACCP Deviation Log Verification Records Pre-shipment Records review form 31 For example, an SOP describing the corrective actions might include this statement \u201ceach carcass with a deviation will be railed out by the employee and reported and shown to the supervisor. The supervisor will determine the cause of the deviation, take whatever measures are necessary to restore the CCP to control, and document the corrective actions in the Corrective Actions log. If more than one deviation is found in a shift, the line will be slowed x% until xx minutes\u2019 production successfully passes the CCP.\u201d 32 One form for all three CCP monitoring locations and

verification activities.", "Page 20 of 20 33 FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat, Poultry and Egg Products identifies the ingredients that are safe to use; however, each establishment must validate their own process. See FSIS Compliance Guideline HACCP Systems Validation for validation guidance. 34 FSIS does not endorse any specific antimicrobial intervention. \u201cOrganic acid\u201d is used as an example. If an antimicrobial is used, each establishment will need to find an antimicrobial intervention that works with their unique situation and they will need to validate the product\u2019s use. The critical limits should closely match the specific parameters for use as found in the technical or scientific supporting documentation. 35 NOTE: Critical operating parameters need to be addressed in this section as they are related to the scientific justification for use. Critical parameters include but are not limited to the following: type of sprayer (hand, cabinet), volume, coverage, chemical contact time, solution temperature, etc. The defined operational parameters are specific to each establishment. Example NSIS Market Hog Slaughter HACCP Plan Critical Control Point (CCP) Significant Hazard(s) Critical Limits for Each Control Measure33 Monitoring Procedures Corrective Action Verification Records What How Frequency Who CCP 4 Organic Acid Spray (Carcass, head meat, cheek meat, weasand meat, and offal) B: Pathogens: Salmonella The application of an organic acid34 (for example, organic acid at 25%). Mix solution per manufacturer\u2019s instructions to achieve 2-5% solution of organic acid not to exceed 55oC (131oF) sprayed directly onto carcasses, head meat, cheek meat, weasand meat and offal at 20-30 psi35 until all surfaces are dripping wet and some of the solution drips off. Observe the preparation and mixing of the solution and its application to verify the operational parameters are achieved. Observe the mixing of the solution and test the concentration of the organic acid (test kit). Observe the pressure gauges to determine the pressure at which the solution is being applied. Check thermometer for the temperature of the solution at the point of application. Observe for complete coverage of the product at the point the solution is applied. Once during each hour of slaughter operations. QA Tech or designee If a deviation from the critical limit occurs, the QA manager or designee will take corrective actions per 9 CFR 417.3(a): 1. Hold all product produced after the last acceptable check until appropriate disposition taken (no product injurious to health will enter commerce); 2. Determine and eliminate the cause of the deviation; 3. Bring the CCP under control; and 4. Take measures to prevent recurrence. Randomly, once per week, QA Manager observes QA Tech performing monitoring functions. Each week, a QA Tech calibrates the pressure of the sprayers per manufacturer\u2019s instructions. Weekly calibrate cabinet thermometers by checking temperature with a calibrated hand-held thermometer. Daily Records Review QA will review Organic Acid Wash CCP CCP 4 Organic Acid Spray Form. Control Point (HACCP) Systems Final Rule in July 1996. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to address safety hazards reasonably likely to occur in their production process. Therefore, this HACCP model's focus, and the focus of the other HACCP models, is on product safety, not product quality characteristics. With the rule, FSIS made available a Guidebook for the Preparation of HACCP Plans and a generic model for each food processing category defined in the regulation (9 CFR 417.2(b)(1)). The guidebook and the generic models have been updated since their initial publication to be consistent with current science and policy. FSIS recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used as is. FSIS recommends that establishments tailor the model(s) to fit the establishment's operation. This generic model uses bacon to illustrate the Heat-Treated, Not Fully Cooked processing category. Bacon is a cured and smoked pork product. Bacon is made with salt as a curing agent. Nitrite is the other most frequently used additive. Bacon may also contain sugars, wood smoke, flavorings, and spices. Bacon receives a heat processing step but the application of heat is not adequate to achieve food safety. Therefore, bacon is not ready-to-eat, it must be kept refrigerated or frozen, and it is cooked before consumption. This model's critical control point (CCP) does not necessarily apply to all operations or bacon products. HACCP plans may require more CCPs depending on the product and the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The food safety critical limits selected must come from scientific documents or other reliable sources to meet regulatory validation requirements. This model includes references for guidance on the selection of critical limits. The selection of this processing category and bacon HACCP model are preliminary steps to completing a hazard analysis. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis are HACCP records ((CFR 417.5(a))). Ensure you maintain the documents produced while developing a HACCP plan. For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP plans and the guidance materials available on the FSIS HACCP webpage." "Page 2 of 14 EXAMPLE PRODUCT DESCRIPTION1 Product Name and Process Type: Bacon (Heat-Treated, Not Fully Cooked) Product Name and Process Type Bacon; Heat-Treated, Not Fully Cooked Important product characteristics (Aw, pH, Preservatives, etc.) Contains Sodium Nitrite (120 ppm)2 How it is to be used3 Intended for cooking Packaging (durability and storage conditions) Vacuum packaged Shelf life and at what temperature4 1 month at 40°F or less or 6 months frozen at 0°F Where it will be sold (specify intended consumers, especially at-risk populations)5 Sold to household consumers through retail outlets or distributed to hotels, restaurants, and institutions (HRI). Labeling instructions and requirements Product name, nutrition facts, ingredients statement, allergen statement, establishment number, keep refrigerated, keep frozen, cooking instructions, safe handling instructions Special distribution control Keep refrigerated or frozen DATE: APPROVED BY: 1 Prior to developing the HACCP plan please read the FSIS Guidebook for the Preparation of

HACCP Plans for detailed descriptions of the worksheets and hazard analysis. The FSIS Guidebook for the Preparation of HACCP Plans and the generic HACCP models are intended for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP models are for demonstration purposes only. The models do not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. 2 Pumped bacon has a regulatory requirement for 120 ppm ingoing Sodium Nitrite or an equivalent amount of potassium nitrite (148 ppm ingoing) and 550 ppm Sodium Ascorbate or Sodium Erythorbate (9 CFR 424.22(b)). 3 The intended use or consumer of the product must be identified in accordance with 9 CFR 417.2(a)(2). Identifying the product\u2019s intended use in the product description is one way to meet the regulatory requirements specific to 417.2(a)(2). 4 Each establishment may have their own defined shelf life. 5 At-risk populations include young children, the elderly, and immunocompromised persons." , "Page 3 of 14

**EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING MATERIAL6** Product Name and Process Type: Bacon (Heat-Treated, Not Fully Cooked) Meat and Meat by-products Pork belly Non-Meat food ingredients Sugar, Salt, Flavor and Spice mixture Antimicrobial interventions<sup>7</sup> and processing aids Sodium Nitrite Packaging material Plastic vacuum bags Restricted ingredients and allergens Sodium Nitrite, Sodium Erythorbate Other None DATE: APPROVED BY: 6 List all meat, non-meat ingredients, restricted ingredients (for example, nitrites), processing aids, packaging material used in production of this product. This is important to help identify any special ingredients or processes to address in the HACCP plan. See the FSIS Compliance Guideline Allergens and Ingredients of Public Health Concern: Identification, Prevention and Control, and Declaration through Labeling for detailed information on allergens. To review restrictions on the use of nitrite and sodium ascorbate or sodium erythorbate, see 9 CFR 424.22(b). 7 FSIS and the Food and Drug Administration (FDA) have a memorandum of understanding (MOU) that establishes the working relationship followed when responding to notifications for the use of food additives (including ingredients) intended for use in the production of FSIS regulated products. FSIS determines the suitability of the use of food ingredients used in the production of meat, poultry, and egg products. FSIS consults, as necessary, with FDA on the requirements under the Federal Food, Drug & Cosmetic Act and its implementing regulations. See FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat Poultry and Egg Products for the list of suitable ingredients." , "Page 4 of 14 **EXAMPLE PROCESS FLOW DIAGRAM8** Product Name and Process Type: Bacon (Heat Treated, Not Fully Cooked) 12. ANALYSIS10 Product Name and Process Type: Bacon (Heat Treated, Not Fully Cooked) 10 See FSIS Salmonella Compliance Guidelines for Small and Very Small Meat and Poultry Establishments that Produce Ready-to-Eat (RTE) Products for suggested best practices and a list of scientific and technical references. 11 Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P). Biological hazards are living organisms. Chemical hazards may be naturally occurring in foods, used, or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification. 12 Place the justification for your decision in column 4. Include control measures in column 4 for hazards not reasonably likely to occur and place them in column 5 for hazards reasonably likely to occur. If a hazard is reasonable likely to occur, then a CCP must be addressed at this step or a later step. See FSIS Meat and Poultry Hazards and Controls Guide for a list of frequently used controls. 13 Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced article must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS program, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peerreviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan. 14 Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5). 15 To determine a CCP, see the Guidebook for the Preparation of HACCP Plans for a decision tree to evaluate the areas of control (column 5) to determine the best CCP to control, reduce, or eliminate a hazard. Column 1 Column 2 Column 3 Column 4 Column 5 Column 6 Ingredient \Process Step Potential Hazards (introduced or controlled) at this Step11 Is the Potential Food Safety Hazard Reasonably Likely to Occur? (Yes or No)12 Justification \ Basis for Decision in Column 313 If \u201cyes\u201d in Column 3 (hazard RLTO), What Control Measures Can Be Applied to Prevent, Eliminate, or Reduce the Hazard to Acceptable Levels14 Is this Step a Critical Control Point (CCP)?15 1. Pork Receiving (fresh) B: Salmonella No It is well documented that raw pork may be contaminated with pathogens. Bacon (like other forms of not ready-to-eat pork products, including all forms of fresh pork) is customarily well-cooked in the home or elsewhere before being served to the consumer and

the product bears safe handling", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 6 of 14 16 See FSIS Compliance Guideline for the Prevention and Control of Trichinella and Other Parasitic Hazards in Pork and Products Containing Pork for more information regarding Trichinella spiralis. 17 Prerequisite programs (SOP, Sanitation SOP, GMP) used as controls must be written procedures or protocols. The name of the program (for example, Receiving Trim SOP) must be listed, and the program and plant data become part of recordkeeping. These programs must have a description of controls and on-going verification used to prevent hazards from occurring. 18 FSIS recognizes the author's work since it was presented at a public hearing on a proposed regulation. The full title of the document is: Tompkin, R.B. 1996. The Significance of time-temperature to growth of foodborne pathogens during refrigeration at 40-50°F. Presented during the Joint FSIS/FDA Conference on Time/Temperature.

November 18, Washington, DC. Trichinella spiralis16 No instructions. Written Pork Receiving Standard Operating Procedure (SOP) to establish controls to prevent hazards.17 Written Pork Receiving SOP followed to establish controls for purchase specifications, ensure only qualified pork products are received and that product has been prepared and handled by the supplier in a manner that minimizes or eliminates the possibility of pathogen contamination. Written Temperature Control SOP for maintaining product at temperatures that preclude bacterial growth (<45°F, (Tompkin, R.B. 1996).18 Letter of Guarantee (LOG) is on file for each supplier of incoming pork. Bacon (like other forms of not ready-to-eat pork products, including all forms of fresh pork) is customarily well-cooked in the home or elsewhere before being served to the consumer. The product bears safe handling instructions. C: None", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 7 of 14 19 This Foreign Material SOP (prerequisite program) should have details on how this procedure is preventing the hazard from occurring (such as metal prevention controls) as well as the on-going verification procedures. These controls should be evident within the written document upon review. The Foreign Material SOP and plant data related to on-going verification activities then become part of recordkeeping and historic data. P: Foreign Material No Written Foreign Material SOP19 for visual inspection of containers and product at receiving. 1a. NonMeat Ingredient Receiving and Storage B: Presence and growth of pathogens e.g., Salmonella, E. coli, Listeria monocytogenes No Spices and flavorings may introduce pathogens. LOGs from suppliers describing quality controls and prevention procedures. Written Incoming Ingredients SOP for procedures to examine incoming non-meat ingredients including temperature (<45°F, (Tompkin, R.B. 1996) and sanitary conditions. Written Sanitation SOP for procedures used to protect ingredients from environmental contamination. C: Allergens, Sodium Nitrite, Sodium Erythorbate No The product formulation does not include an allergenic compound (Big 8). Allergenic ingredients are in other product formulations. Written Sanitation SOP for procedures used to protect non-allergenic ingredients and products from crosscontamination with allergenic ingredients. LOG for all non-meat ingredients describing quality controls and prevention procedures. Written Incoming Ingredients SOP for procedures to examine incoming non-meat ingredients including sanitary conditions. Written Sanitation SOP for procedures used to protect non-meat ingredients from environmental contamination. P: None", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 8 of 14 1b. Packaging Materials Receiving and Storage B: Contamination with Pathogens No Procedures to protect packaging materials from pests and environmental contamination. C: Chemical hazards No Packaging materials may

introduce chemical hazards. Letter of Guarantee for all packaging materials describing quality controls and prevention procedures. Written Packaging Material SOP for procedures to examine incoming materials including sanitary conditions. Written Sanitation SOP for procedures used to protect packaging materials from environmental contamination. P: Physical contaminants No Written Sanitation SOP for procedures used to protect packaging materials from contamination with physical hazards. 2. Cold Storage B: Pathogen outgrowth No Written Sanitation SOP for condition of use in coolers to prevent outgrowth of microorganisms. Written Temperature Control SOP for maintaining product at temperatures that preclude bacterial growth (<45\u00b0F, (Tompkin, R.B. 1996). C: None P: Physical contaminants No Written Sanitation SOP for procedures used to protect packaged product from contamination with physical hazards. B: None", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 9 of 14 3. Weighing and Mixing Marinade Ingredients (including restricted ingredient) C: Sodium Nitrite, Sodium Erythorbate, Allergens No Inappropriate levels of Sodium Nitrite or Sodium Erythorbate added to marinade mix creating potential toxic or uncured condition. Written SOP for Weighing Marinade Spices and Restricted Ingredients. Brine (concentration) records maintained for lots and batching. Written Sanitation SOP for procedures used to protect non-allergenic ingredients and products from crosscontamination with allergenic ingredients. P: None 4. Injecting Pork Belly B: Pathogen outgrowth No Duration of this step (Injecting Pork Belly) is short enough that pathogen outgrowth is not reasonably likely to occur. According to Tompkin, R.B. 1996, Salmonella growth is limited to < 1-log if product temperatures are no more than 70\u00b0F for up to 9 hours. This would be longer than a shift, so outgrowth is not reasonably likely to occur. Bacon (like other forms of not ready-to-eat pork products, including all forms of fresh pork) is customarily well-cooked in the home or elsewhere before being served to the consumer and the product bears safe handling instructions. C: Sodium Nitrite, Sodium Erythorbate No Written SOP for injection process ensures restricted ingredient limits are not exceeded and minimum levels of Sodium Nitrite are achieved. P: Metal from injector needles No Written SOP for equipment inspection during operations. No history of findings from daily equipment preoperational inspections (covered in Sanitation", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 10 of 14 20 Note: this \u201chistorical data\u201d must be supported with evidence from the establishment through the establishment\u2019s history or validation data. When historical data is not available (for example, a HACCP plan for a new process or product), then system design must be supported by other documentary evidence, such as the FSIS Meat and Poultry Hazards and Controls Guide which states \u201capropriate screening procedure for monitoring equipment\u201d is a frequently used control for foreign material hazards in processing. 21 See FSIS Salmonella Compliance Guidelines for Small and Very Small Meat and Poultry Establishments that Produce Ready-to-Eat (RTE) Products and Revised Appendix A for information that small and very small establishments can use to produce safe products with respect to Salmonella and other pathogens. 22 If an establishment implements a process consistent with the process specifications described in the scientific support, and the scientific support contains microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, the in-plant validation data collected during the 90 day initial validation period will consist of data on quantifiable characteristics of the critical operational parameters, such as pressure, temperature, and

concentration. (FSIS Compliance Guideline HACCP Systems Validation, page 27). SOPs).20 No history of consumer complaints. 5. Hanging B: Pathogen outgrowth Duration of this step (Hanging) is short enough that outgrowth is not reasonably likely to occur. According to Tompkin, R.B. 1996, Salmonella growth is limited to < 1-log if product temperatures are no more than 70°F for up to 9 hours. This would be longer than a shift, so outgrowth is not reasonably likely to occur. Bacon (like other forms of not ready-to-eat pork products, including all forms of fresh pork) is customarily well-cooked in the home or elsewhere before being served to the consumer and the product bears safe handling instructions. C: None P: None 6. Smoke (Low Temperature HeatTreatment)21 B: Clostridium perfringens, Clostridium botulinum, and No Pathogens present on raw meat. Pre-requisite formulation SOP to ensure sufficient ingredient levels (salt, brine, sodium nitrite, sodium erythorbate, sodium phosphate) for preventing outgrowth of Staphylococcus aureus, Clostridium perfringens and Clostridium botulinum during smoking.<sup>22</sup>, "Step Potential Hazard RLTO Justification √ Basis Controls CCP Page 11 of 14 23 See FSIS Compliance Guideline for Stabilization (Cooling and Hot-Holding) of Fully and Partially Heat-Treated RTE and NRTE Meat and Poultry Products Produced by Small and Very Small Establishments and the Appendix B for suggested best practices and a list of scientific and technical references. 24 Provide reference for scientific support and validation for effective concentrations and support for critical operational parameters that reduce biological hazards. FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat, Poultry and Egg Products contains the list of substances that may be used in the production of meat and poultry products. The list contains the allowable amounts and the intended use of the approved antimicrobials that can be used as supporting documentation for chemical hazard controls (safety and suitability). Directive 7120.1 cannot be used as support for the control of biological hazards because the antimicrobial concentration needed to control bacteria is different from the concentrations required for safety and suitability. 25 Taormina, P.J. and Bartholomew, G.W. 2005 Validation of Bacon processing Conditions to Verify Control of Clostridium perfringens and Staphylococcus aureus. Journal of Food Protection. 68(9): 1831-1839 Staphylococcus aureus Pre-requisite smoking SOP to ensure heating come up-time is met (heat to 120°F within 6 hours) while natural smoke applied: for preventing outgrowth of Staphylococcus aureus, Clostridium perfringens and Clostridium botulinum during smoking. C: None P: None 7. Cooling23 B: Clostridium perfringens, Clostridium botulinum, Staphylococcus aureus Yes Bacteria can grow and spores can survive the smoke step (#6) and can germinate and grow if not cooled quickly. Bacterial outgrowth can occur if product temperature reduction times are not met. Rapid and controlled cooling ensures no multiplication of toxigenic microorganisms such as Clostridium botulinum and no more than 1-Log multiplication of Clostridium perfringens. CCP 1 Cooling. Pre-requisite formulation SOP to ensure sufficient ingredient levels (salt, brine, sodium nitrite, sodium erythorbate, sodium phosphate) for preventing outgrowth of Staphylococcus aureus, Clostridium perfringens and Clostridium botulinum during cooling.<sup>24,25</sup> Yes, CCP 1 C: None P: None 8. Non-Intact)","num":"FSIS-GD-2021-0003","id":"53420c0c6d825340f611158271f2fb676d4635019e5f8a1b7e5daae76dd6d833","corpus":"fsis\_guidelines","source\_page\_url":"https://www.fsis.usda.gov/policy/fsis-guidelines","url":"https://www.fsis.usda.gov/sites/default/files/media\_file/2021-06/HACCP-Model-Beef-Raw-Non-Intact-2021-0003.pdf","type":"pdf","n\_pages":13,"word\_count":4171,"text\_by\_page":["Page 1 of 13 HACCP Model for Raw Non-Intact Beef The United States Department of Agriculture (USDA) published the Pathogen Reduction\Hazard Analysis Critical Control Point (HACCP) Systems Final Rule in July 1996 mandating all USDA inspected meat and poultry establishments implement a HACCP system. Hazard Analysis Critical Control Point (HACCP) is a systematic and scientific method of process control for the production of safe food products. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to improve the safety of their products. The HACCP models\u2019 focus is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic model for each food processing category defined in the regulation (9 CFR 417.2(b)(1)). The guidebook and the generic models have been revised since their initial publication to be consistent with current science and policy. FSIS recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used \u201cas is\u201d. Establishments are to tailor the model(s) to fit the establishment\u2019s operation. The model\u2019s critical control points (CCPs) do not necessarily apply to all operations or products. Products or operations may require fewer or more CCPs depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The food safety critical limits selected must come from scientific documents or other reliable sources. Each model includes references for guidance on the selection of critical limits. This model illustrates how establishments might include, in the production of ground beef, products from beef intended for intact use and from beef intended for non-intact use. The \u201csources\u201d here include beef from: 1) in-house slaughter product that underwent antimicrobial interventions and verification testing for STEC (shiga toxin-producing E. coli strains O157, O26, O45, O103, O111, O121 and O145); 2) purchased product intended for non-intact use with a certificate of analysis (COA) for STEC testing; and 3) product purchased without a COA and intended for intact use. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis, are HACCP records (CFR 417.5(a)). The selection of processing categories and HACCP models are preliminary steps to completing a hazard analysis. The documents produced during the selection process are HACCP records. Ensure you maintain the documents produced while developing a HACCP plan. For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage."],"Page 2 of 13 EXAMPLE PRODUCT DESCRIPTION1 Process \ Product Name: Raw, Non-Intact Beef Process \ Product Name Raw Non-Intact Beef: Ground Beef, Beef Patties,

Jalapeno Cheddar Burgers, Tenderized Steaks, and Cubed (tenderized) Steaks. Important product characteristics (Aw, pH, preservatives, etc.) None How it is to be used2 Intended for cooking. Packaging (durability and storage conditions) Plastic chubs, tray packages, vacuum sealed packages or in butcher paper. Shelf Life and at what temperature Not shelf stable \u2013 Keep refrigerated (7 days at \u226440\u00b0F) or frozen (180 days at \u226410\u00b0F). Where it will be sold (specify intended consumers, especially at-risk populations3) Sold to household consumers through retail outlets or distributed to hotels, restaurants, and institutions (HRI). Labeling Instructions Product name, inspection legend and establishment number, handling statement, net weight statement, ingredients statement, address line, nutrition facts, and safe handling instructions. Validated cooking instructions for needle and blade tenderized products. What special distribution controls are required? None DATE: APPROVED BY: 1 Prior to developing the HACCP plan please read the FSIS Guidebook for the Preparation of HACCP Plans for detailed descriptions of the worksheets and hazard analysis. The FSIS Guidebook for the Preparation of HACCP Plans and the generic HACCP models are intended for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP models are for demonstration purposes only. The models do not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. 2 The intended use or consumer of the product must be identified in accordance with 9 CFR 417.2(a)(2). Identifying the product's intended use in the product description is one way to meet the regulatory requirements specific to 417.2(a)(2). 3 At-risk populations include young children, the elderly and immunocompromised persons.", "Page 3 of 13 EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING MATERIAL4 Process \ Product Name: Raw, Non-Intact Beef Meat and Meat by-products 1. Beef and beef heart meat intended for non-intact use from In-house slaughter department. 2. Purchased beef intended for non-intact use and with a COA (certificate of analysis). 3. Purchased beef intended for intact use and without a COA. Non-meat food ingredients Wheat, Non-Fat Dry Milk, Soy, Cheese, Vegetables (Jalapenos), binders, spices, seasonings, and solutions for injection. Antimicrobial5 Interventions and processing aids Organic Acid6 Packaging Material Plastic, foam, or paper. Restricted Ingredients and Allergens Allergens - Wheat, Non-Fat Dry Milk, Cheese and Soy. Other None DATE: APPROVED BY: 4 List all meat, non-meat ingredients, restricted ingredients (for example, nitrites), processing aids, packaging material used in production of this product. This is important to help identify any special ingredients or processes to address in the HACCP plan. See the FSIS Compliance Guideline Allergens and Ingredients of Public Health Concern: Identification, Prevention and Control, and Declaration through Labeling for detailed information on allergens. To review restrictions on the use of nitrite and sodium ascorbate or sodium erythorbate, see 9 CFR 424.22(b). 5 FSIS and the Food and Drug Administration (FDA) have a memorandum of understanding (MOU) that establishes the working relationship followed when responding to notifications for the use of food additives (including ingredients) intended for use in the production of FSIS regulated products. FSIS determines the suitability of the use of food ingredients used in the production of meat, poultry, and egg products. FSIS consults, as necessary, with FDA on the requirements under the Federal Food, Drug & Cosmetic Act and its implementing regulations. See FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat, Poultry and Egg Products for the list of suitable ingredients. 6There are many

different organic acids (for example, lactic acid, acetic acid). Establishments will need to research the various organic acids and select a product best suited for their unique circumstances and validate its effectiveness." "Page 4 of 13 EXAMPLE PROCESS FLOW

DIAGRAM7 Process \ Product Name: Raw, Non-Intact Beef 1a. Meat Receiving: Beef and beef heart meat from inhouse slaughter HACCP plan intended for non-intact use<sup>8</sup> 7 This is an example flow diagram. Establishments\u2019 flow diagrams for the same product may be different. Establishments determine which steps are included in their process. The steps must represent all relevant hazards in the hazard analysis.<sup>8</sup> The flow diagram and hazard analysis demonstrate the use of three differently sourced beef products. They are from in-house slaughter production (step 1a) that underwent interventions as part of the slaughter HACCP plan, purchased product intended for nonintact use (with COA) (step 1b) and purchased product intended for intact use (without a COA) (step 1c). Note that CCP 1 Organic Acid Application (step 4) is a control measure only for purchased beef intended for intact use and without a COA. Also note the organic acid application occurs before the beef (in step 1c) is ground or subject to other further processing (step 5). Three source types are used to illustrate how establishments might address STEC in incoming materials that have received different interventions and microbial analysis.

1e. Organic Acid Receiving and Storage 1d. Packaging Materials Receiving and Storage 1b. Meat Receiving: Purchased beef intended for non-intact use and with a COA 1c. Fabrication and Cutting", "Page 5 of 13 EXAMPLE HAZARD ANALYSIS9 Process \ Product Name: Raw, Non-Intact Beef Column 1 Column 2 Column 3 Column 4 Column 5 Column 6 Ingredient \ Process Step Potential Hazards (introduced or controlled) at this Step<sup>10</sup> Is the Potential Food Safety Hazard Reasonably Likely to Occur (RLTO)? (Yes or No)<sup>11</sup> Justification \ Basis for Decision<sup>12</sup> If yes in Column 3 (hazard RLTO), What Control Measures Can Be Applied to Prevent, Eliminate, or Reduce the Hazard to Acceptable Levels<sup>13</sup> Is this Step a Critical Control Point (CCP)? 9 See Meat and Poultry Hazards and Controls Guide for lists of potential biological, physical, and chemical hazards and frequently used controls and preventive measures.

10 Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P). Biological hazards are living organisms. Chemical hazards may be naturally occurring in foods, used or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification.

11 Place the justification for your decision in column 4. Include control measures in column 4 for hazards not reasonably likely to occur and place them in column 5 for hazards reasonably likely to occur. If a hazard is reasonable likely to occur, then a CCP must be addressed at this step or a later step. See FSIS Meat and Poultry Hazards and Controls Guide for a list of frequently used controls.

12 Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced article must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from

an FSIS source, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan. 13 Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5).", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 6 of 13 1a. Meat Receiving: Beef and beef heart meat from in-house slaughter HACCP Plan intended for non-intact use B: Presence of pathogens: - Shiga-toxin producing Escherichia coli (STEC) (E. coli O157:H7, O26, O45, O103, O111, O121 and O145) - Salmonella B: Outgrowth of pathogens STEC and Salmonella. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to address safety hazards reasonably likely to occur in their production process. Therefore, this HACCP model\u2019s focus, and the focus of the other HACCP models, is on product safety, not product quality characteristics. With the rule, FSIS made available a Guidebook for the Preparation of HACCP Plans and a generic model for each food processing category defined in the regulation (9 CFR 417.2(b)(1)). The guidebook and the generic models have been updated since their initial publication to be consistent with current science and policy. FSIS recommends you use of the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used \u201cas is\u201d. FSIS recommends that establishments tailor the model(s) to fit the establishment\u2019s operation. The model\u2019s critical control points (CCPs) do not necessarily apply to all operations or products in the product category. Products or operations may require fewer or more CCPs depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The food safety critical limits selected must come from scientific documents or other reliable sources to meet regulatory validation requirements. Each model includes references for guidance on the selection of critical limits. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis, are HACCP records ((CFR 417.5(a)). The selection of processing categories and HACCP models are preliminary steps to completing a hazard analysis. The documents produced during the selection process are HACCP records. Ensure you maintain the documents produced while developing a HACCP plan. For further

assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage.", "Page 2 of 15 EXAMPLE PRODUCT DESCRIPTION1 PROCESS \ PRODUCT NAME: Beef Jerky (Ready-to-Eat, Heat-Treated, Shelf-Stable) Process \ Product Name Beef Jerky (Ready-to-Eat, Heat-Treated, Shelf-Stable) Important Product Characteristics2 (water activity, pH, Preservatives, etc.) Contains Sodium Nitrite and Sodium Erythorbate Water activity < 0.85 Intended Use Ready-to-eat3 Packaging (Durability and storage conditions) Plastic vacuumed packed single-serve units and stored at ambient temperature Shelf Life and at what temperature 240 days unopened and not refrigerated Where it will be sold (specify intended consumers, especially at-risk populations4) Sold to household consumers through retail outlets or distributed to hotels, restaurants, and institutions (HRI). \_\_\_\_\_ APPROVED BY: 1 Prior to developing the HACCP plan please read the FSIS Guidebook for the Preparation of HACCP Plans for detailed descriptions of the worksheets and hazard analysis. The FSIS Guidebook for the Preparation of HACCP Plans and the generic HACCP models are intended for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP models are for demonstration purposes only. The models do not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. 2 This jerky example is a product cured with sodium nitrite. See the Food Standards and Labeling Policy Book for jerky standards. Examples of jerky standards are products that have a moisture to protein ratio of 0.75:1 or less, they may be cured or uncured, and sodium nitrite is not required. Establishments should gather documentation to support the moisture to protein ratio standard using inplant data collected during initial validation and on-going verification. 3 The intended use or consumer of the product must be identified in accordance with 9 CFR 417.2(a)(2). Identifying the product\u2019s intended use in the product description is one way to meet the regulatory requirements specific to 417.2(a)(2). 3 At-risk populations include young children, the elderly and immunocompromised persons.", "Page 3 of 15 EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING MATERIAL5 Process \ Product Name: Beef Jerky (Ready-to-Eat, Heat-Treated, Shelf-Stable) Meat and Meat by-products Boneless beef top rounds and top sirloins Non-Meat food ingredients Sugar, Salt, Soy Sauce (water, wheat, soybeans, salt, sodium benzoate, brewing starter (*Aspergillus Sojae*)), Flavor and Spice Mixture Antimicrobials6 and processing aids None Packaging material Plastic vacuum bags Restricted ingredients and allergens Sodium Nitrite, Sodium Erythorbate, Soy Sauce (soy and wheat) Other None DATE: \_\_\_\_\_ APPROVED BY: 4 List all meat, non-meat ingredients, restricted ingredients (for example, nitrites), processing aids, packaging material used in production of this product. This is important to help identify any special ingredients or processes to address in the HACCP plan. See the FSIS Compliance Guideline Allergens and Ingredients of Public Health Concern: Identification, Prevention and Control, and Declaration through Labeling for detailed information on allergens. To review restrictions on the use of nitrite and sodium ascorbate or sodium erythorbate, see 9 CFR 424.22(b). 6 FSIS and the Food and Drug Administration (FDA) have a memorandum of understanding (MOU) that establishes the working relationship

followed when responding to notifications for the use of food additives (including ingredients) intended for use in the production of FSIS regulated products. FSIS determines the suitability of the use of food ingredients used in the production of meat, poultry, and egg products. FSIS consults, as necessary, with FDA on the requirements under the Federal Food, Drug & Cosmetic Act and its implementing regulations. See FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat Poultry and Egg Products for the list of suitable ingredients.", "Page 4 of 15

EXAMPLE PROCESS FLOW DIAGRAM<sup>7</sup> Process \ Product Name: Beef Jerky (Ready-to-Eat, Heat-Treated, Shelf-Stable)<sup>8</sup> 11. Returned Product<sup>9</sup> 6 This is an example flow diagram.

Establishments\u2019 flow diagrams for the same product may be different. Establishments determine which steps are included in their process. The steps must represent all relevant hazards in the hazard analysis. 7 For more information on general processing steps used in jerky production see the FSIS Compliance Guideline for Meat and Poultry Jerky Produced by Small and Very Small Establishments. As discussed on pages 6-7, antimicrobial interventions may also be added before, during, or after marinating the strips of raw beef to increase the level of pathogen reduction beyond that achieved by cooking alone. 9 The Returned Product step (12) is shown as not connected to another process step. Returned product may re-enter the production system at different process steps depending on condition or food safety concerns. Returned product may be relabeled, repackaged, or discarded. 8. Packaging and Labeling 9.

Metal Detection 10. Storage and Distribution 1. Beef Receiving 1a. Non-Meat Ingredients Receiving and storage 1b. Packaging Receiving and Storage 2. Cold Storage 3. Slicing 5. Marinate Beef and Place on Racks or Trays 6. Cooking CCP 1 (Lethality Step) 7. Drying CCP 2 4. Weighing and Mixing Marinade Ingredients", "Page 5 of 15 EXAMPLE HAZARD ANALYSIS<sup>10</sup> Beef Jerky: Ready-to-Eat, Heat-Treated, Shelf-Stable 9 See FSIS Compliance Guideline for Meat and Poultry Jerky Produced by Small and Very Small Establishments for suggested best practices and a list of scientific and technical support documents. 11 Hazards are grouped into three categories:

Biological (B), Chemical (C), and Physical (P). Biological hazards are living organisms. Chemical hazards may be naturally occurring in foods, used, or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the

Preparation of HACCP Plans for more information about hazards identification. 12 Place the justification for your decision in column 4. Include control measures in column 4 for hazards not reasonably likely to occur and place them in column 5 for hazards reasonably likely to occur. If a hazard is reasonable likely to occur, then a CCP must be addressed at this step or a later step.

See FSIS Meat and Poultry Hazards and Controls Guide for a list of frequently used controls. 13

Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced article must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS program, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peerreviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan. 14 Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an

establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5). 15 Shiga toxin-producing *Escherichia coli* (STEC) includes serogroups O157:H7, O26, O45, O103, O111, O121 and O145). .....	89","4 Preface This is a revised version of the FSIS Guideline for Controlling Salmonella and Campylobacter in Raw Poultry. This 2021 revision of the guideline was split into two separate documents in response to comments received: one for Salmonella and one for Campylobacter. This guideline represents FSIS\u2019 current thinking on these topics and should be considered usable as of its issuance. The information in this guideline is provided to assist poultry slaughter and processing establishments in controlling hazards and meeting the FSIS pathogen performance standards. The contents of this document do not have the force and effect of law and are not meant to bind the public in any way. This document is intended only to provide clarity to the public regarding existing requirements under the regulations. Under the regulations, establishments may choose to implement different procedures than those outlined in this guideline, but they would need to validate and support how those procedures are effective. This guideline is focused on small and very small establishments in support of the Small Business Administration\u2019s initiative to provide small businesses with compliance assistance under the Small Business Regulatory Enforcement Fairness Act (SBREFA). However, all poultry establishments may apply the recommendations in this guideline. It is important that small and very small establishments have access to a full range of scientific and technical support, and the assistance needed to establish safe and effective Hazard Analysis Critical Control Point (HACCP) systems. FSIS has other guidance documents available for establishments that slaughter and process raw poultry products, including: \u2022 Information about the chilling of poultry products can be found in the Modernization of Poultry Slaughter Inspection: Amendments to Chilling Requirements. \u2022 Information about designing and implementing a microbiological sampling plan can be found in the FSIS Compliance Guideline: Modernization of Poultry Slaughter Inspection - Microbiological Sampling of Raw Poultry. \u2022 Information about controlling Campylobacter and Salmonella in chicken liver can be found in the FSIS Guideline: Chicken Liver. \u2022 Information about controlling Campylobacter can be found in the FSIS Guideline for Controlling Campylobacter in Raw Poultry."5 Congressional Review Act

Pursuant to the Congressional Review Act at 5 U.S.C. 801 et seq., the Office of Information and Regulatory Affairs has determined that this guideline is not a \u201cmajor rule,\u201d as defined by 5 U.S.C. 804(2). Reason for Issuing the Guideline FSIS developed this guideline to assist establishments that slaughter or process raw poultry products to prevent and minimize the risk of Salmonella in their operations. FSIS is updating and reissuing this guideline as part of continuing efforts to assess the scientific support and new technologies available to improve the effectiveness of policy documents and recommendations to industry. Specifically, FSIS revised this guideline to respond to public comments on the 2015 guideline and provide updated information for establishments to use to control pathogens in raw poultry products with the goal of reducing human illnesses from consuming poultry contaminated with Salmonella. In addition, since the 2015 revision, FSIS has implemented pathogen performance standards for chicken parts and comminuted chicken and turkey products. This guideline can assist establishments in meeting the Salmonella performance standards and reducing illnesses associated with Salmonella. This guideline describes concerns and controls for each step in the poultry slaughter process. However, the interventions suggested in this guideline cannot overcome poor preharvest production practices, poor sanitary practices in slaughter and dressing, or poor slaughter and further processing facility sanitation. Establishments can use this guideline to improve management practices, make changes at the appropriate locations, and improve process control. As a result, establishments can produce raw poultry products that have less contamination with pathogens, including Salmonella. Again, the information in this guideline is provided as guidance to assist poultry slaughter and processing establishments in reducing Salmonella contamination and is not legally binding from a regulatory perspective.<sup>6</sup>

Changes from the Previous Version of the Guideline This guideline is final. FSIS will update this guideline as necessary when new information becomes available. FSIS made the following specific changes to the guideline to reflect the peer-reviewed literature and address public comments received on the previous version of the guideline:

- \u2022 Removed the word \u201ccompliance\u201d from the document title and throughout the document to clarify that this document does not constitute regulatory requirements;
- \u2022 Separated the 2015 Draft Compliance Guideline for Controlling Salmonella and Campylobacter in Raw Poultry (4th Edition) into two distinct guidelines, one addressing Salmonella control and one addressing Campylobacter control;
- \u2022 Removed redundant language related to other current FSIS guidelines, providing hyperlinks to those resources where appropriate;
- \u2022 Added relevant, current peer-reviewed science related to poultry slaughter and processing, including a complete revision of the bedding and litter section, and additional literature resources specific to Salmonella;
- \u2022 Added information about antimicrobial carryover and considerations to mitigate its effect on microbiological sampling;
- \u2022 Updated data tables outlining the relative risk of various source materials used in further processed poultry products based on recent FSIS data; and
- \u2022 Updated the sanitizer data table in response to a public comment that pointed to a more recent revision.

How to Effectively Use the Guideline This guideline is organized to provide users with the current science and recommendations. To use this guideline, FSIS recommends that readers use the navigation headings to move efficiently through the document sections of interest. Hyperlinks, where provided, will quickly take you to the correct place in the document electronically and are also provided to other complementary documents. The reference list at the end of the document provides resource material used in

the development of this guidance (References).", "7 Questions Regarding Topics in this Guideline If after reading this guideline you still have questions, FSIS recommends searching the publicly posted Knowledge Articles (\u201cPublic Q&As\u201d) in the askFSIS database. If after searching the database, you still have questions, refer them to the Office of Policy and Program Development through askFSIS and select \u201cSampling\u201d as the Inquiry Type or by telephone at 1-800-233-3935. Documenting these questions helps FSIS improve and refine present and future versions of the guideline and associated issuances. Background FSIS regulated poultry slaughter and processing establishments are required to determine the \u201cfood safety hazards that can occur before, during, and after entry into the establishment\u201d (9 CFR 417.2(a)) in their hazard analysis. Pre-harvest interventions, adequate sanitary dressing procedures at slaughter, and adequate sanitary conditions during further processing are a part of an integrated approach to reduce the public health impact of Salmonella. This pathogen is a hazard that establishments producing raw poultry products can control through a HACCP plan or prevent in the processing environment through a Sanitation Standard Operating Procedures (Sanitation SOPs) or other prerequisite programs. FSIS has determined that contamination of poultry carcasses and parts by fecal material and enteric pathogens (including Salmonella spp.) is a hazard reasonably likely to occur (RLTO) in poultry slaughter establishments unless addressed in a Sanitation SOP or other prerequisite program.<sup>1</sup> For this reason, if an establishment relies on its Sanitation SOP or other prerequisite program to address enteric pathogens, the establishment\u2019s HACCP system must identify why such Sanitation SOP or other prerequisite program results in the enteric pathogens being not reasonably likely to occur (NRLTO). The measures outlined in this document will be most effective at decreasing Salmonella in raw poultry products when considered together. Food Safety and the HACCP Framework Unlike the production of ready-to-eat (RTE) product in which a lethality treatment destroys pathogens of public health concern, slaughter and further processing 1 79 FR 49565 (p.49613) Key Point Federally inspected poultry establishments are required to conduct a hazard analysis as part of their Hazard Analysis and Critical Control Point (HACCP) system. The hazard analysis is required to include \u201cfood safety hazards that can occur before, during, and after entry into the establishment\u201d (9 CFR 417.2(a)).", "8 operations do not have as many available treatment options capable of destroying all pathogens in raw products. Under HACCP regulations, establishments are required to have a system designed to ensure that poultry is processed in a manner that prevents and controls potential contamination hazards that are RLTO during slaughter and processing. Slaughter establishments have controls and procedures in place to reduce the level of incoming contamination on the exterior of the birds and to reduce or mitigate any contamination that can occur throughout the slaughter process. Establishments must document the controls and procedures they use to prevent contamination in their HACCP plan, Sanitation SOP, or applicable prerequisite program in accordance with 9 CFR 417.5.

<https://www.govinfo.gov/content/pkg/CFR-2020-title9-vol2/pdf/CFR-2020-title9-vol2sec417-2.pdf> HACCP Plan to Control Hazards If the establishment decides through its hazard analysis that Salmonella is a food safety hazard RLTO, 9 CFR 417.2 requires that the establishment\u2019s HACCP plan address this food safety hazard. The HACCP plan must meet all parts of 9 CFR 417.2(c), including having a critical control point (CCP) to address the pathogen. A CCP is defined as a point, step, or procedure in a food process at which a control

can be applied, and, as a result, a food safety hazard can be prevented, eliminated, or reduced to an acceptable level. As an example, an establishment might have a CCP at a point during slaughter for applying a validated antimicrobial intervention to carcasses. FSIS requires the establishment to develop critical limits (CLs) for CCPs to control hazards that are RLTO (9 CFR 417.2(c)(3)). CLs are the parameters that indicate whether the control measure at the CCP is in or out of control. A critical limit is the maximum or minimum value to which a physical, biological, or chemical hazard must be controlled at a critical control point to prevent, eliminate, or reduce to an acceptable level the occurrence of the identified food safety hazard (9 CFR 417.1). An example of CLs are the critical operational parameters for an antimicrobial intervention applied to carcasses at a point during slaughter. For example, critical operational parameters of an antimicrobial applied with a spray bar may include concentration, pH, and spray pressure. To determine whether CLs are being met, establishments must monitor them (9 CFR 417.2(c)(4)). Monitoring is a planned sequence of observations or measurements to assess whether a CCP is under control and to produce an accurate record for future use in verification. Monitoring procedures usually involve either a measurement or an observation. For the example of a CCP of applying an antimicrobial intervention during slaughter, monitoring activities might include measuring the concentration, pH, and other critical limits of the antimicrobial intervention, at a frequency sufficient to determine whether the CCP is under control. If a CL is not met, the establishment must meet the corrective action requirements in 9 CFR 417.3. To document whether the establishment meets its CCP, the establishment records its measurements and corrective actions as part of a recordkeeping system." Verification ensures that the HACCP plan is being implemented as written and confirms the accurate monitoring of the CCPs. Guidance on validation and ongoing verification is available in the FSIS HACCP Systems Validation guideline. GENERAL CONSIDERATIONS Sanitation Cleaners and Detergents Cleaning followed by sanitizing is essential to control pathogens (e.g., *Salmonella*) in an establishment. Pathogens can attach to processing equipment or grow on food materials left behind on product contact surfaces. Properly cleaning an area requires removing debris, including dry pickup and pre-rinsing of gross soils, before using a cleaning agent (detergent). Alkaline detergents are frequently used as cleaning agents and vary in strength; examples include sodium hydroxide, nitrous oxide, sodium silicate, and trisodium phosphate (TSP). Acid detergents are also used as cleaning agents and vary in strength; examples include hydrochloric, sulfuric, phosphoric, and acetic acids. Quaternary ammonia is a type of synthetic detergent. Regardless of type of detergent used, they will need to be in contact with surfaces for enough time to ensure effectiveness of the product. Establishments can follow the manufacturer's instructions regarding application and contact time for detergents. Once a surface has been properly cleaned, sanitizers can be applied. There are several types of chemical sanitizers commonly used: quaternary ammonia, industrial strength bleach, iodine compounds, peracetic acid, steam, and ozone. There are areas within an establishment where it may be better to use one type of sanitizer over another. For example, to sanitize aluminum equipment, rubber belts, and tile walls, iodophors (e.g., betadine, iodine) are recommended. Active chlorine is best for other types of walls, wooden crates, and concrete floors. A study of *Salmonella* on food contact surfaces demonstrated biofilm formation on plastic, steel, and concrete surfaces; while iodophors and chlorine sanitizers were still generally effective, a higher contact time or concentration may be necessary when biofilms are present (Joseph, et al.,

2000). A listing of various sanitizers and their associated properties is presented below in Table 1." , "10 Table 1: Factors to Consider in Sanitizer Selection (Ecolab, 2016, 2020) Table 1 provides a comparison of several classes of sanitizers (X-axis) by associated properties (Y-axis).

\*Corrosion properties will depend on grade of stainless steel; ratings were provided assuming 304 stainless steel. \*\*\u201cVariable\u201d indicates that the sanitizer can be a formulated to specific outcome. As outlined in 9 CFR 416, each establishment\u2019s Sanitation SOPs, other prerequisite programs, or HACCP plans should address procedures that ensure that all slaughter and further processing equipment, food contact surfaces, and employees\u2019 hands, tools, and clothing are maintained in a sanitary manner to minimize the potential for cross contamination within and among lots of production. Establishments must develop and effectively implement Sanitation SOPs that address, at a minimum, the handling and cleaning and sanitizing of food contact surfaces, equipment, utensils, implements, and processing areas. The Sanitation SOPs must indicate the frequency with which these items will be cleaned and sanitized and the frequency at which the establishment will verify their cleanliness and removal of product residues." , "11 In addition to achieving pre-operational sanitation, maintaining operational sanitation can minimize cross contamination during poultry slaughter and further processing. Establishments are required to clean and sanitize both food contact and non-foodcontact surfaces as frequently as necessary to prevent the creation of insanitary conditions (9 CFR 416.4). Operational sanitation extends to active practices as well as maintaining sanitary equipment. Sanitation procedures are required to prevent crosscontamination from equipment, personnel, traffic, air flow, tables, and floors to product. Sanitation SOPs are required to ensure establishment employees regularly clean and disinfect knives or other product contact surfaces during use. When employees use knives during carcass trimming or cut-up operations, 9 CFR 416.4(a) requires an establishment to ensure that sanitation is maintained between carcasses. This may be achieved, in part, by sanitizing knives in 180\u00b0F water or antimicrobial-containing water between every carcass and using air or water knives instead of physical knives. Figure 1 shows an establishment employee washing their hands and their knife in water treated with an antimicrobial after cutting wings on each carcass; this is identified as a best practice. Figure 1 Best Practice: Establishment employee washes hands and knife with water treated with an antimicrobial after cutting wings on each carcass. This set up and practice reduces cross-contamination. Figure 2 shows cut-up stations in which fat and other product build up accumulates on the knife sharpeners, which establishment employees use as needed. No water for cleaning is available at each station. These practices are not recommended." , "12 Figure 2 Not Recommended: Cut-up stations do not include a mechanism for cleaning knives. Knife sharpeners are available at each cut-up station and are used as needed. This set up and practice increases crosscontamination. Employees are in continuous contact with the product. The production of wholesome products is difficult when employees do not maintain clean hands and clothing. Therefore, sanitation training and education, as well as supervision, are crucial. Sanitizing stations must be available and maintained for washing hands. It is important that all employees follow standard hygienic practices in accordance with 9 CFR 416.5. Outer garments, head coverings, aprons, gloves, and protective shields are worn to prevent contamination, and cleaned or changed as necessary. Jewelry, cell phones, food (including candy and gum), and tobacco products should be restricted within the establishment. In addition, care taken by employees when performing

tasks, including sanitation procedures, prevents cross-contamination. For example, covering exposed product prior to hosing floors prevents splash-back from contacting product. Figure 3 shows an establishment employee performing manual evisceration. The employee's arm is uncovered and is not being washed sufficiently to prevent crosscontamination, as shown by the organic material present on the bare arm, which may then enter another carcass."<sup>13</sup>

**Figure 3 Not Recommended:** Organic material is present on an establishment employee's arm (yellow arrow). Water is available for washing, but the employee is not washing with sufficient frequency to prevent crosscontamination during manual evisceration. Plastic sleeves are more sanitary and easier to wash than bare arms Sanitation requirements regarding dressing rooms, lavatories, and toilets must be followed per 9 CFR 416.2 (h)(1) and 416.2 (h)(2). Ensuring employee health and hygiene protects employees, product, and consumers. Keeping the processing areas and employee areas clean and in good repair is central to maintaining sanitary conditions. The sections on Slaughter and Further Processing provide additional guidance regarding maintaining sanitation during those processes.

#### Intervention Use

Establishments may choose to implement the use of antimicrobial interventions to prevent or control *Salmonella* contamination. For interventions used that are part of an establishment's HACCP system (HACCP plan, Sanitation SOP, or other prerequisite<sup>14</sup> programs), establishments must maintain scientific support for their effectiveness and implement the interventions according to their support. Because interventions applied as part of an establishment's HACCP system affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these interventions as supporting documentation for its hazard analysis (9 CFR 417.5(a)). Guidance on identifying and selecting critical operational parameters for antimicrobial interventions and validation is available in the FSIS Compliance Guideline HACCP Systems Validation. The guidance document discusses how to apply those parameters within an establishment as part of a HACCP system. FSIS has found that some poultry establishments measure critical operational parameters, such as pH, temperature, and concentration, at the point where chemicals are mixed rather than at the point where they are applied. Values for these parameters can differ between these two locations. For this reason, values including pH, temperature, and concentration are best measured at the point they are applied to the product, rather than where they are mixed or prepared. When selecting an antimicrobial intervention, establishments must ensure that antimicrobial interventions and levels used are safe and suitable. FSIS Directive 7120.1, Safe and Suitable Ingredients used in the Production of Meat, Poultry, and Egg Products, includes a web-based lookup table of antimicrobial agents that have been deemed safe and suitable when applied to certain products. This FSIS Directive is updated monthly. Together, 9 CFR 424.21 and FSIS Directive 7120.1 provide a complete list of substances that have been reviewed and can be used in the production of meat, poultry, and egg products. However, FSIS Directive 7120.1 by itself is not sufficient scientific support for establishments' use of interventions because it does not contain efficacy data or all of the critical operational parameters. FSIS does not endorse the use of any particular antimicrobial agent included in FSIS Directive 7120.1. If a company or establishment wishes to use a substance (e.g., an antimicrobial processing aid applied as a dip or spray) in the production of meat or poultry products that is not listed in FSIS Directive 7120.1, or desires to apply it to a different product or use it at a different level than that for which the substance has been listed, it would need to submit a protocol to FSIS for

review and determination. Additional information on New Technology Submissions and Protocols is available in the FSIS Guideline: Procedures for New Technology Notifications and Protocols. With any antimicrobial intervention, carcass\product coverage is important. Figure 4 below shows examples of incomplete coverage of poultry carcasses and parts. An establishment can use simple verification procedures to ensure an antimicrobial intervention achieves carcass\product coverage. When applying antimicrobial interventions to ground product or to parts that are macerated (or otherwise not Key Point FSIS Directive 7120.1 by itself is not sufficient scientific support for the efficacy of an establishment\u2019s interventions.", "15 smooth), establishments can consider how they will ensure that the intervention will be thoroughly mixed in and cover surfaces where bacteria may be present.

Figure 4 Not Recommended: Incomplete coverage is because of inadequate reach of antimicrobial spray in both images. On the left, only part of the carcass is receiving the spray. On the right, no spray is applied to the underside of products. In addition, not all pieces on the conveyor belt, nor all of the belt, are being treated because the arc of the spray (just inside the yellow lines) is too narrow to cover all product that could pass on the conveyor. Spray is also not being applied to all pieces due to product piling up and overlapping on the conveyor belt. Using Microbiological Sampling and Testing The FSIS Compliance Guideline: Modernization of Poultry Slaughter Inspection - Microbiological Sampling of Raw Poultry provides guidance to help small and very small poultry slaughter establishments meet the sampling and analysis requirements under the final rule to modernize poultry slaughter inspection. It is designed to assist establishments as they develop a microbiological sampling plan; utilize microbial testing results to monitor process control; and make decisions on process control throughout the poultry slaughter process (79 FR 49566) so that the establishment meets the minimum requirements set forth in the final rule. While the Modernization of Poultry Slaughter Inspection - Microbiological Sampling of Raw Poultry Guideline provides guidance on how to meet the minimum requirements under the final rule, establishments may want to consider developing an integrated sampling program that addresses multiple points throughout the poultry production process and includes sampling at points during further processing as well as during slaughter. Microbiological testing provides a measure of the extent of control at the step being evaluated and the steps preceding it. By performing microbiological analyses at several points within a process, it is relatively easy to identify the segment of the process where", "16 there has been a loss of control if that occurs. For example, testing before and after an intervention application can demonstrate whether the expected reduction in contamination is achieved (e.g., that part of the process is \u201cin control\u201d). FSIS regulated establishments may perform microbiological testing (or contract with an outside laboratory to perform such testing) for a variety of reasons, including, but not limited to: 1. Fulfill regulatory requirements; 2. Support on-going verification of the establishment\u2019s HACCP plan (9 CFR 417.4 (a)(2); 3. Support decisions made in the establishment\u2019s hazard analysis and HACCP plan (9 CFR 417.5(a)(1) and 417.5(a)(2); 4. Evaluate the effectiveness of the establishment\u2019s sanitation program (9 CFR 416.14); and 5. Comply with customer\u2019s purchase specifications or requirements. General Considerations for Establishment Ongoing Verification Testing Verification testing is utilized to \u201cverify\u201d (i.e., confirm) that a process is performing as anticipated. Verification differs from validation in that validation utilizes an initial predetermined number of repetitions and tests, while verification involves

ongoing, periodic testing. Process verification testing is intended to demonstrate that the validated process is functioning as designed, and that the results obtained during verification testing are not significantly different than those observed during validation. Verification testing works as one of the pieces of the HACCP system to help inform the establishment of any weak points that may exist in its process and that, consequently, may lead to a loss of process control. Official establishments are responsible for ongoing verification of their entire HACCP system. Therefore, establishments could choose to sample at multiple points in the process to verify that each component of the HACCP system is continuing to function as designed. Testing only finished product will not typically provide the establishment with sufficient information to detect and correct vulnerabilities at specific steps in their HACCP system. Similarly, FSIS verification testing may reveal trends that indicate a vulnerability but are not adequate alone to trace the root cause.

**Key Points** An establishment can sample at multiple points in its process to verify that each component of the HACCP system is continuing to function as designed. Simply testing finished product will not typically provide sufficient information to detect and correct vulnerabilities at specific steps in the HACCP system."

"**17 Process Mapping** One way an establishment could ensure that its HACCP system is effective is to use process mapping. Process mapping (also known as carcass mapping or bio-mapping) can be used as a baseline for assessing the effectiveness of certain interventions as well as the effectiveness of the overall HACCP system. Process mapping is defined as conducting microbial sampling at selected points in the process where contamination levels can be assessed. The assessment measures microbiological loads on carcasses against a specific target organism or class of organisms. Process mapping shows areas where immediate improvements can be made, or where there is a need for process adjustments. A process mapping (testing) protocol could contain procedures for obtaining multiple samples from a single flock after each processing step. Plotting these test results creates a map of the microbial reduction at each intervention step in the system. The plot shows where process control is most effective, least effective, or needs modification. FSIS strongly recommends that establishments use process mapping techniques to develop their own sampling programs for *Salmonella* or indicator organisms.

**Written Microbiological Sampling Program** The written microbiological sampling program at a slaughter establishment is designed in order to (at a minimum) meet the requirements of 9 CFR 381.65(g). Additionally, sampling at both slaughter and further processing may support the HACCP plan by demonstrating control of a hazard or effectiveness of an intervention. The written procedures for sampling and analysis of microbial organisms must be incorporated into the establishment's HACCP Plan, Sanitation SOPs, or other prerequisite program (9 CFR 381.65(g)). The following are the basic elements of a written sampling program:

1. A description of the sample collection procedures, including how sampling that is representative of all lines and production shifts is achieved, how samples are Recommended Best Practices, Statistical Process Control
1. When defining process control limits, verify that the establishment is maintaining process control, so that values within the control limits will be representative of performance when the system is functioning as designed.
2. Statistical control limits that are too tight may be more likely to indicate that process control issues are present when they are not, while limits that are too relaxed may be more likely to miss potential process vulnerabilities.
3. Consider using the *Salmonella* performance standards published by FSIS to establish internal pathogen controls."

"**18 handled to ensure sample integrity**, how the

establishment ensures that samples are collected per the written program, and the establishment employees designated to collect the samples for testing; 2. Information on the method used to analyze the samples and the identity of the laboratory performing the analysis. The method used must be fit-for-purpose, such as an Association of Analytical Chemists (AOAC) official method or one validated by another recognized independent testing body. FSIS provides an online lookup table of Validated Test Kits to assist establishments with identifying applicable options; 3. The microbiological organisms (i.e., *Salmonella* or indicator organisms) that the establishment will test for to monitor the effectiveness of its process control procedures; 4. The locations within the process where samples are collected; 5. The methods to ensure integrity of the samples throughout collection, storage, and analysis; 6. The frequency of sample collection; 7. Scientific and technical documentation to support the design of the sampling program. Further information on scientific and technical documentation can be found in the FSIS Compliance Guideline HACCP Systems Validation; 8. The method for evaluating test results; and 9. Actions to take in response to test results. Designing a Sampling and Testing Program When a microbiological sampling and testing program is properly designed and implemented, it can provide valuable information about an establishment's process control. When not properly designed and implemented, the test results can provide inaccurate and unreliable information that may not represent the establishment's actual process control. This use of inaccurate or unreliable test results could lead to inaction or an inappropriate course of action by establishments and can lead to false assurances of product safety. Effective testing depends on implementation within an establishment's food safety culture. Treating adverse test results as undesirable may introduce bias, as employees may be apprehensive in reporting these findings. A proactive approach to adverse sampling results can prevent a loss of process control at a greater level. Results from "19 laboratory or quality assurance staff may identify negative trends or vulnerabilities in the HACCP system before a hazard reaches the level of not meeting an FSIS pathogen performance standard. There are a number of factors that need to be considered when designing a sampling plan. Sample collection and analysis involves multiple steps, all of which must be successfully performed and documented to maintain the identity and integrity of the sample. Before starting sampling, an establishment needs to consider the design of the sampling program. Establishments can find information on criteria for selecting a commercial or private microbiological testing laboratory to analyze establishment samples in FSIS's Establishment Guidance for the Selection of a Commercial or Private Microbiological Testing Laboratory. Target Organisms Establishments can consider the advantages and disadvantages of testing for the presence of selected indicator bacteria and pathogens for ongoing HACCP verification. Sampling and testing costs for indicator species may be lower than costs for pathogens. However, while elevated levels of indicator bacteria are usually interpreted to mean pathogens are more likely, this relationship is not perfect. In other words, high levels of indicator organisms do not always mean that the pathogen is present, and low levels do not guarantee the pathogen is controlled. Only pathogen testing can effectively verify that pathogens are controlled to acceptable levels in finished product. There are no identified indicator organisms that directly reflect the presence or absence of pathogens (e.g., *Salmonella*) in poultry. Therefore, FSIS recommends that an establishment test for pathogens at least intermittently and compare its results against the presence or absence of other non-pathogenic organisms (i.e., the indicator organisms the

establishment is using) to assess whether it is maintaining process control. The indicator organisms can provide evidence of control, while periodic testing for pathogens may verify that the establishment is reducing pathogens to acceptable levels. Establishments conducting their own ongoing verification sampling and testing of finished product for Salmonella can use the FSIS performance standards as indicators of process control. For example, an establishment could consider the FSIS \u201cmminimum number to assess\u201d for each FSIS performance standard as a guide to ensure that they collect enough data points to have statistical confidence in their pathogen percent positive. For most products, that is roughly one Salmonella sample per month (11 samples/52 weeks for young chicken carcasses, 14 for turkey carcasses, and 10 for chicken parts and comminuted poultry). This approach is supportable if the analytical method has comparable sensitivity to the FSIS method; the less sensitive the method, the more samples are needed to increase confidence in the accuracy of the results.<sup>20</sup> Statistical Process Control Statistical process control is a scientific visual method used to monitor, control, and improve processes by reducing variation from the process. Statistical process control provides a powerful tool for establishments to use to monitor and interpret data collected for ongoing HACCP verification. Statistical process control can provide establishments with an early warning that their process may not be functioning as designed. This early warning can allow establishments to make modifications to bring their process back into control prior to not meeting an FSIS pathogen performance standard or an individual establishment-identified pre-determined performance criteria. Statistical process control can provide establishments with reasonable assurance that their HACCP system is functioning as designed, and that they are likely to meet applicable performance standards. The FSIS Compliance Guideline: Modernization of Poultry Slaughter Inspection - Microbiological Sampling of Raw Poultry provides additional information on sampling frequency and analysis, including the use of statistical process control. A number of methods and approaches for statistical process control are available for establishments to follow. Establishments can consider available guidance and develop a statistically valid approach for interpreting sample results (Saini et al., 2011; De Vries & Reneau 2010). Establishments can consider available information provided by FSIS, including the Salmonella performance standards for young chicken and turkey carcasses, chicken parts and comminuted poultry,<sup>2</sup> to develop their own internal controls for pathogens in these products. FSIS has found that its category approach (Category 1, 2, and 3) to assess process control has worked to identify whether individual establishments are maintaining consistent process control. Establishments developing their own internal pathogen controls can consider how they may apply this concept. Sample Collection Method Proper sample collection techniques and procedures are necessary to ensure the accuracy of test results. Sample handling and collection procedures are specific to the type of product to be sampled (e.g., parts or comminuted), the sample collection method (e.g., parts rinse, comminuted product sampling), and the type of sample collected (e.g., rinsate sample, finished product samples, excision sample of skin). Individuals who will collect samples need to receive training on proper sample collection procedures. 281 FR 7285<sup>21</sup> Antimicrobial Interventions and Drip Time An establishment can consider how sample results are affected by the antimicrobials used in the process and the timing of the sample collection. Antimicrobial interventions used during processing steps may make it more difficult to detect remaining bacteria, particularly when non-destructive or surface sampling is conducted. For destructive sampling, in which the tissue

itself is collected for analysis at the laboratory, remaining antimicrobials will continue to be inactivated by organic material in the sample during shipment of the sample to the laboratory. Conversely, with rinsate or through other surface sampling, capturing the antimicrobial in a buffer or other sampling solution may prolong the antimicrobial's effective time. For example, consider poultry carcasses exiting a chiller tank where antimicrobial interventions are used. Contaminated carcasses may have bacteria that survived the chiller tank. However, those bacteria may not be detected through sampling if the carcass is not allowed adequate drip time before the establishment collects a rinse sample. Adequate drip time will allow excess antimicrobials to drip off the carcass. Immediate sample collection will include a significant amount of residual antimicrobials, which suspended in rinsate will remain active and make it harder for the laboratory to detect live bacteria. If the carcass is allowed adequate drip time, the sample will contain less residual antimicrobials, and the laboratory will be more likely to detect live bacteria. At this time, FSIS generally recommends establishments wait at least 60 seconds after application of antimicrobial interventions before collecting a sample to reduce the amount of antimicrobial carryover. A longer drip time may be recommended by the antimicrobial manufacturer for particular solutions. Tipping over the carcass to allow drainage of chiller water that has accumulated in the body cavity can also result in greater accuracy of the test result. Establishments could consider whether a neutralizing agent is available which could stop the action of any residual antimicrobial intervention, making it possible to more accurately detect live bacteria remaining on the sample. Examples of a neutralizing agent suited for particular antimicrobials would include lecithin for Cetylpyridinium Chloride (CPC), sodium thiosulfate for Peroxyacetic Acid (PAA), or sodium thiosulfate plus bicarbonate for Acidified Sodium Chlorite (ASC) (Gamble et al., 2016). To effectively use quantitative data to evaluate process control, the collection, handling, storage, and transportation of samples are carefully controlled to prevent temperature abuse, sample leakage, and other events that could affect sample integrity and lead to unreliable test results. Procedures for maintaining sample integrity are particularly important when samples need to be transported from the establishment to an off-site laboratory (e.g., by a delivery service, such as FedEx or courier) where they may not be under the direct control of the establishment or the laboratory for a period of time.<sup>22</sup>

**Selection of Products for Sampling** The samples are selected and collected in a manner and at a frequency that will ensure that they are representative of the establishment's production. If more than one shift is operating at the establishment, a sample can be taken on any shift. All shifts are sampled with sufficient frequency in order to assess process control for each shift. The FSIS Compliance Guideline: Modernization of Poultry Slaughter Inspection - Microbiological Sampling of Raw Poultry provides information on methods for selection of carcasses for sampling during the slaughter process. In order to meet the requirements of 9 CFR 381.65(g), slaughter establishments must sample carcasses at the pre- and post-chill locations (very small establishments are only required to test at post-chill). The same selection techniques can also be applied to further processed products in support of a HACCP system. Different methods of selecting the specific products for sampling can be used, but all require the use of random numbers to reduce bias. Examples of methods for selecting products for sampling include random number tables, calculator- or computer-generated random numbers, or drawing cards. **Sample Analysis** To obtain the most accurate microbiological testing results, establishments ensure the following: Recommended Best Practices, Ongoing Verification

Testing 1. Establishments must maintain support for their verification procedures and frequencies. (9 CFR 417.2(c)(7)) 2. Both indicator bacteria and pathogens can provide useful information. 3. Allow at least 60 seconds before sampling after application of any antimicrobials, to prevent excessive antimicrobial carryover in the collected sample.", "23 \u2022 The collected sample is either analyzed in the establishment the same day as it is collected or by the following day. If shipping to an offsite laboratory, the sample can be held under refrigeration until overnight shipment to the laboratory the day of collection or the following day. \u2022 Samples can be held at refrigerated temperature, not frozen, and shipped cold to the laboratory in an insulated shipping container with frozen gel packs. Frozen samples are discarded since the sample results may not be accurate.

**Microbiological Testing Method**

An establishment needs to determine whether sample analysis will be performed by an outside (third party) laboratory or in its own onsite microbiological testing laboratory (if available). Because of the costs and the logistics involved with maintaining an onsite microbiological testing laboratory, establishments may choose to have samples analyzed by an outside laboratory. FSIS has available the resource titled Establishment Guidance for the Selection of a Commercial or Private Microbiological Testing Laboratory. This guideline is intended to be useful to very small establishments when they are selecting a commercial or private laboratory to analyze their microbiological samples.

**NOTE:** Establishments can (and often do) analyze samples for non-pathogenic organisms, such as generic E. coli and APC, on-site.

**Recordkeeping**

Upon implementation of its sampling program, an establishment must maintain daily records sufficient to document the samples collected and subsequent test results. For slaughter establishments, records must document the required sampling, as outlined by 9 CFR 381.65(h). Daily sampling records that best support analysis of the sample results include: \u2022 Time, date, and location of the sample collection; \u2022 Sample collector's name; \u2022 Name or description of the product or sample source; and \u2022 Lot information and producer.

**Key Points**

To obtain the most accurate results, samples are analyzed as soon after collection as possible. If samples must be transported to an off-site laboratory, they can be refrigerated and then shipped refrigerated, on the same day they were collected or the following day, via an overnight delivery service to the laboratory.", "24 A best practice is for all sample records to be dated and initialed by the sample collector immediately upon completion of the entry. If an outside laboratory is used for testing, then these sample records would also include information such as date the sample was shipped to the laboratory for analysis. The receiving laboratory will document the: \u2022 Date received; \u2022 Condition of the sample upon receipt, including sample temperature; \u2022 Date the analysis was started and completed; and the \u2022 Analytical result. Test results are best recorded and linked to the sample collection records by a sample number, form number or some other unique identifier.

Data integrity is a key consideration when determining how to maintain these records. These records can be maintained in an electronic format, provided there are measures in place to ensure the security of the information. These records must be available for FSIS inspection program personnel upon request.

**Actions in Response to Test Results**

As part of its process control procedures, an establishment defines the actions it will take if the test results obtained through its sampling are above the limits it has set. The establishment delineates what its actions will be, who will take each action, how the outcome of these actions will be documented, and how it will be verified. If the establishment determines that the trends in its

test results indicate a loss of process control, the establishment can first take action to investigate the cause. As discussed in the previous section on process control, an establishment can consider how the pieces of the HACCP system work together, and how they impact the entire system. To do this, the establishment can evaluate the process control procedures and sanitary dressing practices to identify the cause and to take steps to correct the problem. This determination can include a review of its process monitoring records as well as an evaluation of the process during normal operations. The establishment can consider any implementation problems or changes in its practices, including but not limited to the following:

1. Implementation problems or changes in procedures for routine cleaning and sanitizing of equipment, including hand tools that are used to remove contamination or to make cuts into the carcass; 2. Changes in the design, configuration, and calibration of equipment to ensure proper function within operational parameters to prevent the contact between carcasses and parts and prevent contamination of carcasses during operation;" "25 3. Implementation problems or changes in employee hygiene practices, to ensure that employees frequently wash hands and aprons that come in contact with carcasses; and 4. Implementation problems or changes in antimicrobial or mechanical intervention treatments, such as carcass washes, sprays, dips, drenches, or brushes, in accordance with the limits selected by the establishment.

Following its investigation, the establishment responds appropriately to its findings using decontamination procedures and antimicrobial intervention treatments as necessary to address any contamination that may have occurred on the carcasses and parts. The establishment can also take steps to initiate any necessary equipment repair or recalibration and employee training when identified during the investigation as potential root causes of the loss in process control. Depending on how the establishment has incorporated sampling and sanitary dressing into the written programs, the establishment may also need to perform and document corrective actions as required by Sanitation SOP (9 CFR 416.15) or HACCP (9 CFR 417.3(a)) PRE-HARVEST Pre-Harvest Interventions and Management Practices Pre-harvest interventions and practices can prevent or reduce *Salmonella* colonization of live birds, increasing the effectiveness of post-slaughter interventions and establishment controls. This section identifies available pre-harvest interventions\practices, and how slaughter and processing

establishments can encourage their use by poultry producers. This section covers poultry production from breeder stock through transport to the slaughter establishment. Live receiving and subsequent slaughter steps are covered in the following section. Food Safety Hazards Colonization of the poultry gastrointestinal tract with *Salmonella* is a food safety hazard that can occur at pre-harvest (i.e., at grow-out, the hatchery, or at the breeder farm). Colonization can then result in fecal shedding of bacteria, which can contaminate skin and feathers during many steps from breeder farm to arrival at the slaughter establishment. External contamination can also occur during slaughter from rupture of the gastrointestinal tract and transfer of pathogens on contaminated equipment. FSISregulated establishments can, as part of their overall HACCP system, address these hazards through purchase specifications or other agreements to require that their suppliers implement certain pre-harvest management controls." "26 Pre-Harvest Interventions & Management Practices FSIS recommends that establishments use two main practices for managing preharvest colonization of poultry with *Salmonella*. Together, these practices are expected to reduce the number of birds colonized with or shedding pathogens, reduce the number of these pathogens in colonized birds, and

reduce the likelihood that contamination will be transferred from colonized to uncolonized birds. First, FSIS recommends that slaughter establishments receive birds from grow-out farms, hatcheries, and breeder flocks that implement the recognized pre-harvest interventions described in this section. Implementing these interventions can decrease the Salmonella contamination on birds received by slaughter and processing establishments (Cox & Pavic 2010; Volkova et al. 2011). Establishments may include specifications in their grow-out contracts for growers to incorporate strategies that address the potential contamination of Salmonella during hatching and grow-out. Reducing or eliminating Salmonella on incoming birds at slaughter establishments can reduce contamination of finished products and increase the likelihood that the establishment will meet FSIS performance standards for Salmonella.

Alternately, if an establishment does not require that Salmonella is addressed at preharvest, FSIS recommends that slaughter and processing establishments test incoming birds and poultry products before entry into the establishment and make processing decisions based on those test results. Further information about using pre-harvest sampling data for decision-making can be found in the following section, Scheduled Slaughter and Processing. Using these test results, an establishment could decide to implement a scheduled slaughter and processing plan based on the presence or absence (\u201cstatus\u201d) of Salmonella. Other decisions could be to utilize additional chemical interventions or divert products from positive flocks to lethality treatment (such as cooking). Scheduled Slaughter & Processing Maximizing the amount of finished product that is negative for Salmonella can be achieved by implementing a scheduled slaughter and processing plan based on the status of incoming birds. Scheduled slaughter and processing depend on lotting definitions that ensure lots are microbiologically independent. To implement a scheduled slaughter and processing plan, establishments must determine the Salmonella status of poultry flocks before their entry into the establishment. Using this information, establishments can then schedule pathogen-negative flocks for slaughter and processing separately from pathogenpositive flocks. \u201cSeparately\u201d can be defined as different slaughter and processing establishments, different production lines in the same establishment, or at different times on the same production line (negative before positive and lines are cleaned and sanitized before negative flocks or products). Establishments can also choose to utilize", "27 additional interventions or lethality treatments, such as cooking, for product derived from pathogen-positive flocks. Step One: Determine Salmonella Flock Status The first step in scheduled slaughter and processing is to obtain accurate and reliable information about the Salmonella prevalence in the live birds at pre-harvest. Status can be determined as close to slaughter as possible in order to increase the likelihood that Salmonella will be detectable through drag swabs, boot samples, or litter samples. However, the results need to be available to the establishment early enough to take action. This typically means sampling between 2 and 5 days before transport to slaughter. Further information on sampling in the grow-out house can be found under the heading Determining Flock Pathogen Status Prior to Harvest, in the Pre-Harvest section of this guidance. Step Two: Separate Slaughter and Processing Positive or negative flock status can be maintained throughout slaughter and processing, including if carcasses or parts are moved to other establishments for further processing. For example, if a negative flock is slaughtered separately from a positive flock, but the carcasses and parts are commingled during storage or further processing, all product can be considered positive (microbiological independence is not in place). In cases where positive and

negative flocks are slaughtered and processed on the same line, establishments will need to evaluate their process to determine where to establish independence between lots. If there is no clear break, the establishment can consider carcasses or other raw poultry components to be positive until the next cleaning and sanitizing is performed. For example, all carcasses in the chiller tank at the time the first carcass from a positive flock enters the tank can be considered positive, even if some of the carcasses originated from negative flocks. Then, the establishment can consider all carcasses passing through the tank to be positive until the production line is cleaned and sanitized.

**Step Three: Further Processing or Cooking Establishments** can also choose to utilize additional interventions for poultry products derived from positive flocks. Use of interventions could be based on the establishment's knowledge of the log reduction achievable through the interventions and processes used. Alternatively, positive birds and products could be sent to cooking or another lethality treatment in order to achieve full lethality for any *Salmonella* present in the affected product. Key Point Status can be maintained throughout slaughter and processing, including if carcasses or parts are moved to other establishments for further processing.

"**28 Pre-harvest Recommendations to Control *Salmonella*** This section provides information on interventions intended to prevent the exposure of birds to pathogens and available products intended to reduce the incidence or level of *Salmonella*. Interventions to prevent exposure and colonization in live birds are typically more effective than products that treat birds exposed to *Salmonella* to reduce incidence or levels, as it is more difficult to eliminate *Salmonella* from infected flocks. There are numerous routes of exposure to *Salmonella* during pre-harvest including:

- \u2022 Transmission through the egg from the breeder flock to chicks (vertical transmission) and transmission between birds during hatch and grow-out;
- \u2022 Exposure to contaminated water, feed, and bedding in the grow-out house; and
- \u2022 Environmental exposures due to poor biosecurity practices and inadequate pest control.

FSIS is not aware of a single pre-harvest intervention that eliminates *Salmonella* as a pre-harvest hazard. Instead, FSIS recommends that a multi-hurdle approach be employed; this means that multiple sequential pathogen interventions are used that can have an additive effect to reduce pathogens. Implementing multiple interventions and controls beginning at preharvest extends the multi-hurdle approach to *Salmonella* prevention and control across each bird's life. Using interventions with differing modes of action can further improve the extent of pathogen reduction when using a multi-hurdle approach. In this Guideline, FSIS is providing available effectiveness data for pre-harvest interventions, as identified in scientific literature. However, because many factors during the pre-harvest period can contribute to pathogen colonization of individual birds, the spread of pathogens between birds in a flock, and the excretion of pathogens by birds, use of a particular Recommended Best Practices, Scheduled Slaughter & Processing

1. Use microbiologically independent lotting practices to minimize commingling or cross-contamination.
2. Determine the presence or absence of *Salmonella* before flocks are transferred to slaughter.
3. Slaughter and process negative flocks separately from positive flocks (different establishment, different line, or on sanitized equipment).
4. Consider the use of additional interventions or cooking for product derived from positive flocks and poultry products.

**Key Points** Interventions to prevent exposure and colonization in live birds are preferable as it is more difficult to eliminate *Salmonella* from flocks once infected. Preventive interventions in live birds lose effectiveness if the flock is already infected. Consider using

multiple interventions throughout preharvest.", "29 intervention may have different efficacy than specified. Thus, the concept of a multihurdle approach is important to keep in mind. Establishments can consider requiring suppliers to use the interventions listed here. Establishments can use these pre-harvest controls as part of their HACCP system (through purchase specifications or other agreements) and to support their decisionmaking. FSIS will work with other federal agencies, such as USDA-Animal and Plant Health Inspection Service (APHIS), Food and Drug Administration (FDA), and USDAAgricultural Research Service (ARS), to develop additional information on pre-harvest interventions. This Guideline breaks the pre-harvest interventions into six categories focused on physical, biological, and hygienic approaches to reduce pre-harvest exposure to *Salmonella*: Breeder Flock & Hatchery, Grow-out House, Bedding, Feed, Water, and Transportation. When considering the control of hazards on incoming birds, slaughter establishments can consider exposure-reducing interventions combined with one or more of the products available for pre-harvest control to reduce incidence or levels of *Salmonella* in poultry that may be exposed to these pathogens (Table 2). These products have different modes of action, but all produce the same result: reduced incidence of pathogen colonization and reduced pathogen levels in colonized birds. Efficacy depends on the specific product, and most can be used in consultation with a veterinarian. Using both types of pre-harvest approaches \u2014 those to reduce exposure and those that reduce incidence of colonization and levels of pathogens \u2014 will minimize pathogens on birds at harvest. Using the interventions and best practices recommended in this guideline can help to provide for animal welfare and bird health at pre-harvest, thereby reducing stress in poultry and reducing *Salmonella* in birds presented at slaughter. Evidence suggests that stress at pre-harvest can have adverse effects on food safety (Rostagno, 2009). Understanding the mechanism by which stress alters normal intestinal characteristics and induces susceptibility to enteric infections may help in developing additional preharvest strategies to reduce pathogen contamination in poultry. NOTE: In this section, the term '\u201cyoung chickens\u201d refers to all chickens raised for slaughter to distinguish it from chicken breeder stock. The term here is not limited to '\u201cbroilers\u201d as defined in 9 CFR 381.170(a)(1)(iii). In this section, '\u201cyoung turkeys\u201d refers to all turkeys raised for slaughter to distinguish it from turkey breeder stock." "30 Table 2. Pre-harvest products to reduce colonization and number (level) of *Salmonella* in poultry. Definition Notes on Use Vaccines: increase immunity to *Salmonella* by exposing the immune system to a controlled preparation. Vaccine types include live vaccines (an attenuated strain of *Salmonella*), subunit vaccines (a vaccine with minimal parts of the target for immune response), and autogenous vaccines (developed from bacteria isolated from the farm environment). Approved live-attenuated3 vaccines are available for use in breeder flocks and in young chickens and young turkeys and are administered orally or by injection. Other vaccine types, such as inactivated vaccines, may require multiple doses in order to produce the immune benefits. Special approvals from APHIS are required for long-term use of autogenous vaccines or for use of these vaccines with multiple flocks. Some vaccines were found to show a 9% reduction in *Salmonella* prevalence, a 1-2 log reduction, or a 2-3 log reduction of *Salmonella* recovered from poultry challenged after vaccination. Competitive Exclusion & Probiotics: preparations of beneficial bacteria that compete with *Salmonella* in the gut for space or nutrients. Also known as direct-fed microbials. Some products can be used on the day of hatch to establish healthy gut flora in chicks. Other products can be added to water

and feed for both breeders and young chickens and used to boost competition against pathogens throughout the bird's lifetime or when otherwise indicated (e.g., stress). One study on the effectiveness of a competitive exclusion culture in poultry found up to a 92% reduction of Salmonella following a Salmonella challenge. Prebiotics: specific nutrients that will allow beneficial bacterial species to more effectively compete against Salmonella. Can be added to the feed of both breeders and young chickens. The most common supplements include yeast extracts, such as beta-glucans and mannan oligosaccharides A study on the effectiveness of a prebiotic in poultry found a 34% reduction of Salmonella prevalence following Salmonella challenge. Organic Acids: increase the acidity of the gut, which can kill Salmonella. Because each bacterial species has a different susceptibility to organic acids, this can be added to both feed and water for breeders and young chickens. Adding to water during feed withdrawal is particularly important. After feed is withdrawn, birds may be more likely to peck at litter and may ingest pathogens. Additionally, during feed withdrawal, the gastrointestinal (GI) tract becomes 3 Live Salmonella vaccines administered to poultry presented for slaughter may have the potential to introduce a hazard into the establishment. Establishments should support how their use of such vaccines does not affect safety of poultry products derived from vaccinated poultry and does not interfere with FSIS inspection procedures.", "31 mechanism also increases the ability of beneficial bacteria to compete against pathogens. more susceptible to colonization by Salmonella because of the reduced organic acid concentration and higher pH. Organic acids added to the water will lower the pH in the crop and reduce pathogen colonization and growth. A review article found that use of most organic acid products resulted in up to a 1 log reduction of Salmonella. (References: Berge and Wierup 2012; Callaway et al. 2008; Desin, K\uf6ster, and Potter 2013; Feberwee et al. 2001; Hume et al. 1998; Khan et al. 2003; Penha et al 2009; Spring et al. 2000; Wales et al. 2013) Breeder Flock & Hatchery Breeder flocks and hatcheries can be the original source of Salmonella colonization for young chickens because infection can be transmitted through the egg (vertical transmission). Establishments can obtain broiler and turkey chicks from breeder flocks and hatcheries that follow National Poultry Improvement Plan (NPIP) procedures and recommendations. The NPIP was established in the early 1930's to provide a cooperative industry, state, and federal program through which new diagnostic technology can be effectively applied to the improvement of poultry and poultry products throughout the country. Because of the possibility of vertical transmission, establishment parent companies and independent growers can consider placing chicken and turkey chicks from breeder flocks free of Salmonella onto grow-out farms (Liljeblad et al. 2005; Crespo et al. 2004). (Note that pathogen-free breeder stock is not a requirement for participation in NPIP.) Chicken breeders also demonstrate variability in innate immunity to Salmonella; some chicken breeder stocks have been shown to be more resistant to colonization (Swaggerty et al. 2009). Utilization of these parental breeding stocks can produce broiler chicks that are more resistant to on-farm colonization. Consider the use of one or more of the products listed in Table 2 to prevent or reduce colonization with Salmonella in live birds that are destined for slaughter. Several of the probiotic, prebiotic, and organic acid products can be administered to both breeder flocks and young chickens, often through feed and water. Of special note for breeder flocks are vaccines for Salmonella, which can reduce the likelihood of vertical transmission to chicks (Desin, K\uf6ster, & Potter, 2013). Compared to the short grow-out period for young chickens, breeder flocks may remain productive for several months

or longer. As a result, a greater number of vaccine options are available in breeders compared to young chickens and turkeys. Competitive exclusion and probiotics can be administered to chicks on the day of hatch to inoculate the gastrointestinal tract with beneficial bacteria (Table 2). Inoculation with beneficial bacteria at the hatchery can be followed with use of appropriate prebiotics and organic acids at the grow-out house to maintain beneficial bacteria through growout. Chicks can be transported from the hatchery to the grow-out house in new or,"32 cleaned\sanitized, and ideally lined, containers (Cox & Pavic, 2010). Limit the number of individuals handling the chicks from the truck to the interior of the grow-out house to minimize chances for exposure. Although the following sections focus on young chickens and turkeys, the best practices identified also apply to chicken and turkey breeders and can serve to minimize pathogens in these flocks. Grow-out Houses Farms and houses can be designed to facilitate cleaning and disinfection between flocks (Cox & Pavic, 2010; Volkova et al., 2011). All poultry farms can develop and implement written biosecurity and hygiene plans. Poultry health is best monitored under the supervision of a veterinarian. Available research suggests that the following practices are correlated with a decreased likelihood of *Salmonella* in birds presented for slaughter (Cox & Pavic, 2010; Volkova et al., 2011; C. Wray et al., 1999): \u2022 Housing a single species (e.g., only chickens or only turkeys) on the farm; \u2022 Keeping birds of different ages in different houses; \u2022 Limiting the number of people with access to grow-out houses and using disinfecting boot dips or disposable foot coverings and disposable coveralls when entering the house (a study by Rabie et al. (2015) found that correct use of a boot dip effectively reduced *Salmonella*, although organic material can negatively impact effectiveness); \u2022 Removing vegetation around buildings, installing screens on windows and other openings, and increasing physical integrity of buildings to prevent access by rodents, birds, or insects; and \u2022 Using pest control measures including bait and traps.

Recommended Best Practices, Breeder Flock and Hatchery 1. Obtain chicks from pathogen-free breeder flocks and from breeders and hatcheries following NPIP procedures. 2. Use breeding stock with innate resistance to *Salmonella*. 3. Consider using one or more of the products listed in Table 4. 4. Transport chicks to grow-out in new or sanitized containers.", "33 In addition to reducing exposure to *Salmonella* with the measures described above, consider the use of one or more of the products in Table 2 to reduce colonization and the incidence or level of pathogens in exposed birds. Most probiotics, prebiotics, and organic acids can be used with both breeder and broiler flocks as feed or water additives. Vaccines remain an option for broiler flocks; however, manufacturer information can be used to determine whether immune protection can be achieved during the short grow-out period. Approved live-attenuated vaccines are available for use in young chickens and turkeys. Biologics, including vaccines and antibody products, are licensed for use by USDAAPHIS, which updates the complete listing on their webpage. Live vaccines may introduce *Salmonella* into flocks presented for slaughter; the establishment can consider this possibility when developing the HACCP plan and sampling programs accordingly. Bedding Litter or bedding can be considered a reservoir for *Salmonella* contamination (Bryan et al., 1979; Corrier et al., 1999). Downtime between flocks is recommended at around 10 -14 days, which allows moisture removal and desiccation of litter. Ensure that no new moisture is added and that wet caked areas are removed during the litter turn over (fluff). There are technologies that allow composting or windrowing of litter between flocks (Malone & Johnson, 2011; Wilkinson et al., 2011; Macklin et al., 2008). It is important to

note that litter is not uniform in moisture, organic carbon availability, pH, or microbial populations, which are all factors that can influence pathogen destruction or growth in litter during and following composting. Recommended Best Practices, Grow-out House 1. Implement on-farm biosecurity and hygiene plans, 2. Minimize the number of people with access to the grow-out house. 3. Require the use of disposable foot coverings or boot dips. 4. Consider the use of products in Table 4. Key Points Pre-harvest interventions must not: 1) Negatively impact product safety, 2) Jeopardize the safety of Federal inspection program personnel, 3) Interfere with inspection procedures, including FSIS sampling, or 4) Conflict with the Agency's regulations.", "34 Water activity ( $Aw$ ) and pH of the litter are positively correlated with pathogen growth (Opara, 1992; Terzich, 2000). Consider chemical treatment of the litter to reduce pH and  $Aw$  during production to reduce pathogen growth and contamination of the flock, which could reduce pathogen recovery at the processing establishment. Litter treatments to reduce pH are commonly added prior to flock placement because the early grow-out phase (~1st week for young chickens, ~ 3 weeks for turkeys) is when the birds are most susceptible to pathogen colonization (Santos et al., 2005; Payne et al., 2007). Several chemical additives have been used to decrease the pH of poultry litter, such as aluminum sulfate (Moore & Miller, 1994; Line, 2002), ferrous sulfate (Huff et al., 1984), phosphoric acid (Reece et al., 1979), sodium bisulfate (Moore et al., 1996) (Terzich, 1997), and acetic acid (Parkhurst et al., 1974). Experts recommend a pH of less than 4 to control *Salmonella* growth in litter and to prevent acid-tolerance in some strains of *Salmonella*. (Hardin & Roney, 1989; Payne et al., 2002; Payne et al., 2007). Reducing litter pH to less than 4 can reduce *Salmonella* to below detectable limits (Payne et al., 2007). Since litter pH increases to near neutral after the first week of production, reapplication of the litter treatment may be needed (Pope & Cherry, 2000). During grow-out, moisture in the house can be controlled with the use of tunnel ventilation systems. If the moisture in the litter is too high (as observed in the winter months due to decreased ventilation) *Salmonella* growth can increase. Wet litter can also be caused by environmental conditions (rain, poor drainage, leaky roofs), evaporative cooling systems, excess drinking, health problems, panting, excess bird density, and watering systems such as type of waterers (bell, trough, nipple), leaky valves, maladjusted waterers, too many birds per drinker, or broken water lines. *Salmonella*-positive birds can also spread the pathogen via aerosol when the environment is too dry (Gast et al., 2004). Feed Select growers that use feed that is free of *Salmonella*. Specifically, obtain feed from manufacturers that follow Good Manufacturing Practices to reduce or eliminate pathogens, such as those certified by the Safe Feed/Safe Food program administered by the American Feed Industry Association. Safe Feed/Safe Food producers may also conduct finished product testing to verify the product is negative of certain hazards. Clean and disinfect feeders between flocks and keep feeders in good repair. Consider adopting the use of feed additives that are effective in young chickens (Table 2). Recommended Best Practices, Bedding 1. Use a litter treatment to reduce litter pH  $< 4$  and  $Aw < 0.84$ . 2. Use a composting or windrow treatment during flock downtime. 3. Allow 10-14 days between flocks to desiccate litter and verify destruction of pathogens.", "35 Protect feed from contamination during transportation and storage. Transport the feed to the farm in accordance with the FDA's Sanitary Transportation of Human and Animal Food final rule (81 FR 20091), which includes provisions for cleaning transportation vehicles before transport of feed and measures to prevent contamination or tampering of feed during transportation. Store feed on-farm in a

manner that reduces the likelihood of contamination through contact with pests, fomites, or the environment (Berge & Wierup, 2012). If feed is stored on-farm in a manner that could result in contamination (such as open bins or bags), poultry producers can conduct periodic sampling of the feed to determine whether contamination has occurred during storage. Some research indicates that pelleted feed is more resistant to contamination during storage than mash, and that the addition of organic acids to the feed may also protect against contamination. The Association of American Feed Control Officials (AAFCO) provides additional recommendations on the production and distribution of animal feed in its document titled \u201cBest Management Practices for Manufacturing, Packaging & Distributing Animal Feeds and Feed Ingredients.\u201d Time feed withdrawal appropriately; withdrawal from feed can occur between 8 \u2013 12 hours before slaughter (Cox & Pavic, 2010). Withdrawing feed before slaughter can ensure that birds have an empty gastrointestinal tract during transport, slaughter, and evisceration, which can reduce external contamination with fecal material. However, some research indicates that early withdrawal may lead the birds to peck at the litter in the grow-out house and increase the likelihood that the bird will ingest pathogens and be contaminated at slaughter (Berge & Wierup, 2012). Also, the decrease in the acidity of the crop caused by the removal of feed that beneficial crop bacteria use to form organic acids allows *Salmonella* to grow in the crop (Hinton et al., 2000a, 2000b) because of a lower organic acid concentration and higher pH. Growers can consider providing water with organic acids (Table 2 and discussed below) during feed withdrawal to prevent colonization of the crop. Extended feed withdrawal may also make internal organs more fragile, increasing the likelihood that the crop or other organs will tear during processing and contaminate the carcass (Cox & Pavic, 2010). Most studies support a feed withdrawal period of 8-12 hours to prevent organ tearing (Rostagno et al., 2006; Cox & Pavic, 2010). Recommended Best Practices, Feed 1. Clean feeders between flocks. 2. Use feed that is pathogen free. 3. Consider use of appropriate feed additives (Table 4). 4. Protect feed from contamination during transport and storage 5. Pelleted and acidified feed may be more resistant to contamination during storage. 6. Time feed withdrawal appropriately (between 8 \u2013 12 hours) and supply water with organic acids during feed withdrawal.", "36 Water Provide abundant, potable water (Cox & Pavic 2010). If water is not from a chlorinated or municipal source, routine testing is recommended to ensure that the source is free of pathogens. Clean the water distribution system between flocks, ensuring that biofilms, which may be reservoirs for pathogens, are removed when possible. Ensure that the water system is free of cracks and leaks to minimize waste and to keep bedding dry. A number of the products listed in Table 2 are available as water additives for young chickens. Of note are organic acids added to water, particularly during feed withdrawal (Berge & Wierup 2012). Providing water during feed withdrawal distracts birds from pecking at the litter. Adding organic acids to this water source will increase the acidity of the crop, which can help protect the bird against any *Salmonella* they may ingest when pecking at the litter. Determining Flock Pathogen Status Prior to Harvest Understanding pathogen status on farm or at grow-out, prior to collecting birds for harvest, can provide valuable information to inform establishment decision-making for slaughter and further processing. Additional information and considerations to Recommended Best Practices, Water 1. Provide abundant, potable water. 2. Clean water distribution systems between flocks. 3. Consider feed and water additives listed in Table 4, particularly organic acids during feed withdrawal. Key Points Boot Swabs: single-use covers are placed over the

wearer's boots. After walking through the growout house, the covers are sent for lab analysis. Provides a measure of the entire house. Drag Swabs: collection swabs are dragged on strings throughout the grow-out house and sent for lab analysis. Provides a measure of the entire house. Litter Samples: a portion of the litter is collected and sent for lab analysis. Can only indicate contamination for the collected sample. Cloacal Swabs: a swab is used to collect material from the cloaca of a single bird. Multiple swabs can be collected but results will only represent the birds that are tested." "37 maximize use of on-farm sampling results can be found under the Scheduled Slaughter & Processing section. Pathogen status of the birds in each grow-out house can be determined. This may provide more accurate information than only sampling on farms, where only a portion of houses have colonized birds. In addition, this gives establishments the option to schedule negative houses separately from positive houses, provided the birds in negative versus positive houses can be transported separately. Several methods are available for collecting and analyzing samples from grow-out houses. Some studies suggest that boot swabs may be more sensitive than drag swabs, litter samples, or cloacal swabs; boot swabs provide establishments with a single sample site that represents conditions throughout the poultry house (MuellerDoblies et al., 2009). Samples can be analyzed for Salmonella. Recent research has shown that at least 30% of broiler flocks are Salmonella negative, based on testing fecal samples collected on the farm prior to slaughter or cecal samples collected at slaughter (Thakur et al., 2013). Flocks and houses that are negative for Salmonella can be considered negative for scheduled slaughter purposes. Flocks and houses that are positive for Salmonella can be considered positive for scheduled slaughter purposes.

Transportation The presence of Salmonella on birds at receiving at slaughter has been linked to dirty transport cages (Cory, et al., 2002; Slader, et al., 2002). Cross contamination of both birds and cages is frequently made worse when the birds are transported to the establishment. To prevent such contamination, transport birds in clean containers (Cox & Pavic 2010). Clean, single-use paper liners can be used when transporting chicks but are not recommended for transporting young chickens to slaughter. In all cases, clean and disinfect transportation cages between each load. Minimize the number of individuals involved in removing birds from the grow-out houses. Figure 5 shows a chicken transport crate that is not washed after every load." "38 Figure 5 Not Recommended: Transport crate that is not washed with sufficient frequency. There is a buildup of fecal material and feathers that can contaminate subsequent flocks during transport. Using cleaned and disinfected transport cages for each load of birds is especially important after flocks have been sampled prior to harvest. This is because contamination from dirty cages can change the pathogen status of a flock from negative to positive and reduce the effectiveness of scheduled slaughter and processing decisions.

Research suggests that a two-step process that first cleans and then disinfects the cages is effective at reducing Salmonella. Pre-cleaning the cages prior to immersing in hot water for 30 seconds at 60 °C (140 °F) or higher or immersing for 30 seconds in a solution of sodium hypochlorite at 750 ppm or higher reduces Salmonella on transport cages (Ramesh, et al., 2004).

Recommended Best Practices, Transportation

1. Use clean containers and sanitize containers between loads.
2. Use new disposable paper liners when transporting chicks to the farm.
3. Minimize number of individuals involved in transport.
4. Clean and disinfect transport crates between each load."

"39 SLAUGHTER AND PROCESSING Slaughter This section of the guideline provides information for establishments that slaughter poultry. The diagram below

presents the steps in poultry slaughter addressed in this section. How well an establishment conducts its slaughter dressing procedures has a direct bearing on whether the decontamination and antimicrobial intervention treatments in place in a poultry operation will have their intended effects. When contamination", "40 overwhelms the decontamination efforts and antimicrobial intervention treatments, the establishment may need to take additional steps to reduce pathogens. Live Receiving and Live Hanging This is the point in the slaughter process where poultry arrive at the establishment in transport crates or cages, are unloaded, and are hung on shackles. There is a potential for contamination with enteric pathogens including Salmonella. The feathers, skin, crop, colon, ceca, and cloaca of birds brought to slaughter are often highly contaminated with Salmonella (Kotula & Pandya, 1995). As described in the previous section, transport cages have been found to be sources of cross contamination of pathogens onto live birds transported to slaughter. Cleaning followed by sanitation of the unloading and holding area is important. High levels of Salmonella found on incoming birds can overwhelm establishment interventions. These levels are carried forward to the next steps of the slaughter process. Studies show links between Salmonella at live receiving and later in the process (Fluckey, et al., 2003). Employee traffic patterns and air flow can be controlled to prevent cross contamination and reduce levels of Salmonella. There can be positive airflow moving from inside to outside of the establishment. Standard operating procedures and training, including changing clothes and boots upon arrival, separate facilities for \u201cdirty\u201d versus \u201cclean\u201d employees, and restricting employee movement are measures that can be put in place. Most establishments keep detailed records of suppliers and slaughter schedules by lots to monitor output or yields of products. An establishment could use these records to correlate its own in-house testing programs to determine if there are suppliers that routinely deliver birds carrying a high microbial load. Addressing potential contamination sources with suppliers could lower the microbial level of incoming birds at receiving and thereby reduce microbial loads, particularly pathogens, in chilled carcasses. Recommended Best Practices - Live Receiving and Hanging 1. Control airflow and traffic patterns. 2. Provide SOP and employee training. 3. Schedule flocks for slaughter based on pathogen loads. Key Points The feathers, skin, crop, colon, ceca, and cloaca of birds brought to slaughter are often highly contaminated with Salmonella. Transport cages are an important source of cross contamination of birds with Salmonella.", "41 Stunning and Bleeding This is the point in the slaughter process where the bird is stunned, cut, and bled. Stunning methods render birds unconscious. The method of stunning may be electrical, mechanical, or chemical. Bleeding ensures death by slaughter and ensures that poultry have stopped breathing before going into the scalding tank (9 CFR 381.65(b)). Stunning reduces struggling and convulsions. However, wing flapping and quivering that may happen because of the electrical stunning can transfer bacterial pathogens from the inside to the outside of the bird and to nearby birds and equipment. Continuous Gas Stunning, or Controlled Atmospheric Stunning (CAS), is an additional available stunning method that uses a combination of gases to stun the birds before they are hung on the line. Any stunning method must be monitored and controlled to ensure effectiveness. By decreasing the amount of feces expressed, establishments can reduce fecal cross-contamination on the surface of the carcasses, in the scald tank, and on the feather removal equipment. This decreases the level of Salmonella carried forward into the next steps. Figure 6 shows young chickens entering the stunner with minimal external fecal contamination.

Figure 6 Best practice: These young chickens show minimal fecal contamination on their feathers as they enter the stunner. These birds are calmly entering the stunner.", "42 Scalding Scalding prepares carcasses for defeathering by breaking down the proteins that hold the feathers in place and opening up the feather follicles. It is the point in the slaughter process where the carcasses are placed in hot water in order to facilitate feather removal and is the first location during processing where carcasses are exposed to a common bath, which can allow Salmonella cells from positive carcasses to spread Salmonella to negative carcasses (Russell, 2012). However, scalding can reduce levels of Salmonella on the carcasses, since much of the dirt, litter, and feces on carcasses is removed at this step. Salmonella contamination consistently decreases when scalding is well controlled. Scalder water that contains high concentrations of fecal material is a problem. Birds may come into slaughter facilities with excessive fecal material on the feathers, which gets washed off in the scalder water. Figure 7 shows an immersion scald tank with excessive fecal material contamination. Salmonella has been recovered from 100% of the skin and feather samples entering the scald tank in some experiments (Geornaras, et al., 1997) and has been shown to survive in the scald tank. Bacteria present in the dirty water may be massaged into the skin and open feather follicles. Also, the organic material may be retained on the surface of the bird through evisceration and end up in the chiller, deactivating the chlorine and preventing disinfection. Scalding cannot overcome high numbers of pathogens carried forward from previous steps. To reduce this problem, a bird brush and washer used prior to the scalder can remove some of the incoming dirt and fecal material. There are two methods for scalding: \u2022 steam-spraying \u2022 immersion Steam spray systems work by applying a mixture of steam and air at a temperature and pressure designed to scald the surface of carcasses. Immersion scalding is carried out by placing the carcasses into a tank of hot water. Tanks are either single- or multistage. Immersion is more common than steam-spraying. However, under the right conditions, both methods can reduce Salmonella on carcasses (Dickens, 1989). Recommended Best Practices \u2013 Stunning and Bleeding 1. Electrical stunning and chemical (gas) stunning are very effective stunning methods when implemented correctly. 2. Use well-timed feed withdrawal practices to reduce feces release during stunning.", "43 Figure 7 Not recommended: Excessive fecal material is present in the scalder Several considerations can mitigate contamination at the scalding steps. Water flowing into the tank ideally moves through the system flowing against incoming carcasses. This flow creates a dirty-to-clean gradient. Carcasses moving through the tank are washed by ever-cleaner water. Multiple stages create more opportunities to clean the carcasses (Cason, et al., 2000). High flow rates of water and adequate agitation dilute the dry matter and bacterial load in the tank (Cason, et al., 2001). The water pH is a key operational parameter to monitor. A higher, more alkaline pH (9.0 \u00b1 .2) is best for reducing Salmonella in the water (Humphrey & Lanning, 1987). Making the pH more acidic (3-4) is also effective at decreasing levels of Salmonella (Okrend, et al., 1986)). Establishments can initially monitor the pH in scald tanks as frequently as necessary to determine the pH highs and lows occurring during operation. Once establishments can maintain a desirable pH, less monitoring is needed. Uric acid from poultry feces can reduce the pH from 8.4 to 6.0 in less than 2 hours (Humphrey, 1981). Organic matter in the tank acts as a buffer to maintain a more neutral pH (6-7). Salmonella is more heat resistant at a neutral pH (Okrend, et al., 1986). Understanding water characteristics is an important aspect in poultry slaughter operations. The source (well or treated surface water or

municipal water), hardness, mineral content, and pH influence the killing action of any antimicrobial chemicals that are added to the water, and water hardness may affect the ability of water to wash Key Points Scalding is an important step that can reduce levels of *Salmonella* on the carcasses. Water pH is a key parameter to monitor. Scalding can be used as an intervention if pH is properly maintained in the scald tank.","44 bacteria from the skin of carcasses during processing (Hinton & Holser, 2009). Poultry establishments using more than one water source might consider the potential effect of the water source on the chemicals used. FSIS Directive 7120.1 Safe and Suitable Ingredients used in the Production of Meat, Poultry, and Egg Products and 9 CFR 424.21 provides a lookup table of approved chemicals that can be used in scalders. Most U.S. poultry processors prefer a hard scald to a soft scald. A hard scald is a shorter scald time at higher temperatures compared to a soft scald. This approach allows better removal of the outer layer of skin (epidermis). The correct water temperature for the appropriate amount of time is important to prepare the carcasses for feather removal. The correct water temperature also reduces dressing defects. When the water temperature is too high, the carcasses become oily. This oiliness makes it easier for *Salmonella* to stick to the surface of the skin. If the carcasses are overscalded, the meat may start to cook, and the carcasses may be marked unacceptable and rejected by inspectors for over-scald per 9 CFR 381.92. If the temperature is too low, the tank becomes a breeding ground for bacteria. *Salmonella* cannot grow at temperatures greater than 116.6 °F (47°C). Therefore, scalding temperatures higher than 116.6°F (47°C) can be sufficient to control *Salmonella* growth. Table 3 shows common scalding times and temperatures for various classes of poultry.

Temperature (°F)	Time (seconds)	Class
138.2	59-64	Broiler (hard scald)
123.8-129.2	51-54	Broiler (soft scald)
138.2-145.4	59-63	Turkey

Reduction of *Salmonella* during scalding generally increases with higher water temperatures (Yang et al., 2001). While scalding above 116.6 °F (47 °C) controls *Salmonella* growth and initiates inactivation, scalding at 140 °F (60 °C) reduced counts by an additional 0.3 log units more than scalding at 125.6 °F (52 °C) or 132 °F (56 °C) (Slavik et al., 1995). Yang et al. (2001) also found that scalding at 140 °F (60 °C) resulted in reductions similar to scalding at 131 °F (55 °C). Some religious traditions forbid scalding. Under Kosher slaughter, carcasses are soaked in cold water to make feather removal easier. This method, as well as the steam spray method, may produce carcasses with skin more susceptible to *Salmonella* (Clouser, et al., 1995). Establishments can consider this potential effect in deciding what sanitary practices they employ downstream because the high number of 45 pathogens not reduced during scalding can be transferred to future steps in the slaughter process.

**Picking** The feather removal process is designed to remove feathers and the uppermost layer of the skin before evisceration. Carcasses typically pass through rubber picking fingers that mechanically remove feathers from the carcass. Most establishments use a continuous process. However, batch (not continuous; done at specific, defined and limited times) and manual processes are sometimes used in low-volume establishments. Good process controls at picking are critical. Cross-contamination of the carcasses with *Salmonella* occurs during picking because of contact with contaminated rubber picking fingers and contaminated reuse water (Geornaras, et al., 1997). Fecal material is released when picking fingers agitate and rub the carcasses and can lead to crosscontamination

with fecal material between the carcasses (Allen, et al., 2003). Several researchers have determined that levels of *Salmonella* increase during this step (Berrang, et al., 2011). Regular equipment sanitation and maintenance are recommended to minimize crosscontamination when using either batch or continuous picking. Post-feather removal Recommended Best Practices \u2013 Scalding 1. Have water moving counter current to carcasses. 2. Have high flow rates of water with adequate agitation to dilute dry matter and bacteria. 3. Use multi-staged tanks. 4. Maintain water pH at either above or below the optimum pH for *Salmonella* growth (6.5-7.5). 5. Use pre-scald brush systems to clean birds prior to scald tank. 6. Maintain hard scald temperatures of 140 \u00baF and above.", "46 rinses for carcasses is ideally maintained at 160\u00b0 F. Chlorine, acetic acid, and hydrogen peroxide are types of chemical rinses used during defeathering. If birds are plucked manually, the establishment can prevent crosscontamination by keeping the picking area as clean as possible and preventing feather buildup. Establishments can apply washes or antimicrobial interventions post-picking. However, cut surfaces of hocks must not be washed until FSIS postmortem inspection is complete (9 CFR 381.76, Post-mortem inspection). Otherwise pathological exudate could be removed or obscured and prevent detection of synovitis by inspectors. Water reuse is addressed in 9 CFR 416.2(g)(3). This regulation states that water, ice, and solutions may be reused for the same purpose if measures are taken to reduce physical, chemical, and microbiological contamination so as to prevent contamination or adulteration of product. An establishment is required to have data to support all decisions regarding reuse, including a decision that reuse will or will not cause adulteration (9 CFR 416.2(g)(2)). Recommended Best Practices \u2013 Picking 1. Prevent feather buildup on equipment. 2. Regular cleaning and maintenance of rubber picking fingers. 3. Ensure coverage of sanitizer on picking rails and equipment. 4. Use a post picking antimicrobial intervention rinse. 5. Scientifically support any water reuse plan. Key Points Good process control procedures at picking are critical and can reduce *Salmonella*. Fecal material is released when picking fingers agitate and rub the carcasses and can lead to crosscontamination between the carcasses.", "47 Evisceration Evisceration is the point in the process where removal of the internal organs, and any processing defects, from the poultry carcasses occurs in preparation for chilling. Evisceration includes multiple processes. It begins at the transfer point (i.e., re-hang) and ends when the carcass enters the chiller. It is the point in the slaughter process where the removal of the viscera (including the gastrointestinal tract and edible offal such as heart, liver, and gizzard) occurs by automated or manual means, along with any trim of processing defects from the poultry carcasses in preparation for chilling. If viscera are not handled properly, or if employee hygiene practices are not followed, an increase in microbial contamination can occur. Feed withdrawal practices affect process control at this step. For the evisceration process to work well, carcasses need to be placed on the shackles correctly and monitored as they move through the system. Blades are ideally kept sharpened, and attention given to routine and thorough cleaning. Figure 8 shows an automated opener system that utilizes replaceable blades that are cleaned between each carcass. Figure 8 Best practice: Replaceable blades (middle of picture) are washed between each carcass (yellow arrows) to reduce cross contamination. Blades are replaced daily, which minimizes cross contamination as compared to blades that are replaced less often. Key Points Evisceration begins at rehang and ends when the carcass enters the chiller. Feed withdrawal practices affect process control throughout the evisceration step. For the evisceration processes to work efficiently, carcasses

need to be placed on the shackles correctly and machinery needs to be adjusted to accommodate bird size.", "48 Keeping the equipment in good sanitary condition, free from intestinal contents and segments, is important for maintaining good process control. Figure 9 shows viscera that was caught in the machine as well as fat and tissue build up on breast plates and other surfaces that is not being sufficiently rinsed and cleaned between carcasses. These practices can lead to cross contamination. Figure 9 Not recommended: Viscera are stuck in machine and there is product build up on breast plates and bars around wings and legs (yellow arrows). Automated transfer (re-hang), rather than manual transfer, of carcasses between the defeathering and evisceration lines can reduce external surface cross-contamination.

Equipment used throughout the evisceration process can be installed, adjustments made, and machine performance calibrated effectively to handle the size, shape, gender, feed digestion capability, and live average weights of the birds to be slaughtered. These considerations apply to manual evisceration processes as well. Figure 10 shows a manual venting gun that is rinsed with chlorinated water between each carcass. Processing flocks with varying weight ranges can result in evisceration machinery performing poorly. Inconsistent carcass sizes (for example, because of poor bird size uniformity within a grower house or processing male and female birds together) can result in mis-cuts and fecal contamination. If machines are set for the median weight of the flock, poultry carcasses that are heavier or lighter may not be properly eviscerated. If carcasses are lighter or heavier than the machines can accommodate, the carcasses are more likely to have their gastrointestinal (GI) tracts split open, resulting in contamination of both carcasses and equipment. The machines need to be maintained", "49 in optimum condition and be properly aligned. Failure to maintain eviscerators in optimum condition can result in damaged intestines leading to carcass contamination. Equipment such as crop removal devices can easily become contaminated with *Salmonella*, causing carcasses to later become cross contaminated (Mead et al., 1994). Retracting the viscera from the body cavity can transfer crop and upper GI contents to the interior body cavity (Byrd et al., 2002). In some operations, at least half of carcass surfaces are contaminated with crop and upper GI contents immediately before evisceration (Byrd et al., 2002). Poultry establishments can benefit from awareness of these factors that lead to contamination and can implement necessary machinery checks to ensure that evisceration equipment is indeed functioning effectively.

Figure 10 Best practice: This manual venting gun is rinsed with chlorinated water, supplied to the gun by the red hose, between each carcass. Carcass rinses or sprays can be effective interventions for removing incidental contamination from the carcass surface during evisceration. Studies have shown that *Salmonella* prevalence on carcasses can be reduced by 50-90% following rinses (Buncic & Sofos, 2012). These rinses complement consistent sanitary dressing procedures to control pathogens. A 20 ppm free available chlorine rinse postevisceration can decrease microbial contamination and improve food safety (Waldroup, et al., 1992). The incidence of *Salmonella*-positive carcasses can decrease by one third", "50 when carcass rinses are incorporated into the evisceration process (Notermans, et al., 1980). When applying water rinses and sprays, establishments can consider the water pressure applied. Some studies have found that elevated spray pressure may force bacteria into muscle or skin rather than washing it off (Buncic & Sofos, 2012). Note: This guideline uses the term \u201cfree available chlorine\u201d when referring to parts per million (ppm) chlorine. Free available chlorine is the concentration of hypochlorous acid (HOCl) and hypochlorite ions (OCL) existing

in chlorinated water. (Reference: Handbook of Chlorination and Alternative Disinfectants, Geo. Clifford White, Fourth Edition 1998. Wiley Interscience). Rinses or sprays can be designed, installed, and calibrated to remove incidental contamination. When not properly designed or implemented, rinses or sprays may not effectively remove contamination and may even spread contamination from one part of the carcasses to another part or even to adjacent carcasses. Figure 11 shows a rinse that is not calibrated to wash contamination. Figure 12 shows sprays that spread contamination onto other parts of the carcass. Figure 11 Not recommended: Rinses are not positioned to wash contamination off tail area. On the left, a contaminated carcass moves on the line toward two washes. On the right, the carcass has moved past the washes, and the contamination remains. In this situation, if the nozzles are moved up, it is likely that due to the high pressure and angle of the spray, contamination may not be washed off but instead may spread to surrounding areas of the carcass. Key Point Antimicrobial interventions are not a substitute for consistently implementing sanitary dressing practices", "51 Figure 12 Not recommended: Overspray spreads contamination to adjacent areas of the carcass. In the closeup on the right, the middle spray bar results in splashing of water from the thigh up over the back of the thigh and onto the abdomen area (under yellow arrow), where it will run down the breast area. The contaminated vent area visible on the left (inside the red box) will not be washed off when it goes through the middle spray bar. Instead it will spread contamination to adjacent areas. This is also true of the faint yellow contamination on the outside of the thigh and bird's side (black bar of the right image). Multiple Salmonella controls throughout the evisceration process are recommended. Pathogens are not effectively removed by using one carcass rinse, and a multiple hurdle approach works best against pathogens. Some poultry processors consistently produce Salmonella positive carcasses, while others produce carcasses that upon testing typically do not have detectable levels of Salmonella. These variable test results may be the result of differences in sanitary dressing practices. Sanitary dressing practices are implemented throughout the slaughter process, in a manner that produces a clean, safe, wholesome poultry product in a sanitary manner. For example, rates of visible contamination on the carcasses after crop removal vary greatly depending on crop removal practices. In some establishments, fewer crops rupture because the crops are extracted toward the head (and downward) rather than toward the thoracic inlet (and upward) (Buhr et al., 2000). This is an important consideration for Salmonella control because crop tissue often contains Salmonella (Hargis et al., 1995). Note that some carcasses may become incidentally contaminated with feces and ingesta even with strict sanitary dressing practices. However, fecal contamination can be minimized with strict sanitary dressing practices.", "52 Chilling This is the point where eviscerated carcasses are chilled in order to inhibit microbial growth and meet the regulatory requirements of 9 CFR 381.66(b)(3). Additional information on chilling requirements can be found in the FSIS compliance guide Modernization of Poultry Slaughter Inspection: Chilling Requirements. Antimicrobial Intervention Use for On-line and Offline Reprocessing and for Chilling Procedures Reprocessing systems are used to control Salmonella on visibly contaminated carcasses. Both on-line (OLR) and off-line (OFLR) reprocessing systems can be used to remove incidental contamination during evisceration. On-line reprocessing is not a remedy or a substitute for poor sanitary dressing practices during evisceration. The on-line reprocessing system may be able to remove visible contamination, but the invisible contamination can remain if the intervention is overwhelmed. NOTE: Carcasses must be free of

visible fecal contamination prior to entering the chilling system as required by 9 CFR 381.65(f). Recommended Best Practices \u2013 Evisceration 1. Adjust and maintain equipment regularly as needed to accommodate bird size. 2. Implement an antimicrobial rinse to reduce equipment contamination. 3. Implement multiple hurdles to reduce pathogens.", "53 FSIS has posted lists of the approved OLR and OFLR systems. The lists are regularly updated and attached to FSIS Directive 7120.1, Safe and Suitable Ingredients Used in The Production of Meat, Poultry, and Egg Products. If an establishment desires to use an OLR or OFLR system that has not been approved by FSIS\u2019s Risk Management and Innovations Staff (RMIS) or wishes to modify an approved OLR or OFLR system, the establishment is responsible for submitting a protocol requesting permission to conduct an in-plant trial. Per the Memorandum of Understanding (MOU) between FDA and FSIS, FSIS would consult with FDA regarding safety of the proposed chemical. FSIS would review the protocol for any prohibitions that can potentially affect product safety, safety of inspection personnel, interfere with inspection procedures, or require a change to the Agency\u2019s regulations. If the in-plant trial is granted, FSIS would issue a letter granting permission to conduct an in-plant trial. More information regarding in-plant trials can be found in the FSIS Compliance Guideline Procedures for New Technology Notifications and Protocols. An establishment that uses chlorine or other antimicrobials as a part of its sanitary dressing and process control procedures or employs a pre-chill carcass wash that may affect the pH of the chiller water should consider the effect of pH on the efficacy of any antimicrobials used in the chiller. On Line Reprocessing Addresses incidental fecal or ingesta contamination during evisceration Utilizes washing systems and antimicrobial systems to achieve desired results. Off line Reprocessing Addresses disease conditions and contamination that cannot be removed by other means Produces carcasses microbiologically equivalent to those routinely eviscerated on line", "54 Further Processing This section of the guideline provides information for establishments that further process raw poultry carcasses to produce products such as: \u2022 Poultry parts \u2022 Injected, mechanically tenderized, or vacuum tumbled poultry products \u2022 Commminuted (including ground) poultry products (includes products such as patties and sausages that are made using comminuted poultry) \u2022 Stuffed chicken products Raw Source Material Considerations and the HACCP System There are two different sources for raw materials used in further processing: 1) in-house source materials (e.g., source materials from an establishment\u2019s own slaughter operation) and 2) incoming source materials from one or more supplying establishments. An establishment\u2019s knowledge of the production of source materials from its own slaughter operation is different than the knowledge of the production of purchased or otherwise incoming product because it will have more information about product derived from its own slaughter operations. Whether the source of raw materials used in further processing is another establishment, an establishment\u2019s own slaughter operations, or both, an establishment can consider how the source materials it uses in its processes can affect food safety decisions. A prudent establishment would incorporate this knowledge into its hazard analysis decisions to inform development of its HACCP system, including developing Sanitation SOPs and other prerequisite programs, and CCPs in the HACCP plan. Along these lines, if an establishment produces a raw or otherwise Not-Ready-To-Eat (NRTE) chicken product from parts received from other establishments, it can consider using only parts that are at or below a specific Salmonella percent positive as the source material for making this product. The

receiving establishment may also specify maximum levels for contamination (enumeration). In this scenario, considering the carcass category of the supplying establishment (e.g., only accepting parts from FSIS Salmonella Performance Standards carcass category 1 establishments) would not be as useful because parts and not carcasses are the immediate source materials. FSIS sampling of the industry indicates that pathogen prevalence increases as products are further processed from carcasses, to parts, to comminuted product. It is unclear what benefit requirements for carcasses would provide when the incoming source materials used to produce the finished products are not carcasses. Category 1 carcasses may go on to further processing within an establishment and be cross-contaminated or Key Point Comminuted products are those that are ground, mechanically separated, or hand- or mechanically-deboned and further chopped, flaked, minced or otherwise processed to reduce particle size.", "55 otherwise processed to result in a higher level of pathogens on chicken parts (or comminuted) than the carcass results would suggest. In-House Source materials Slaughter establishments that further process carcasses they produce are self-suppliers (they produce in-house source materials). For in-house source materials, the establishment has direct knowledge regarding the source materials\u2019 production, including pre-harvest information, sanitary dressing procedures, zero tolerance findings, antimicrobial treatments and records of critical operating parameters, and any microbial testing data. The establishment also has direct control of its processes and can monitor, verify, and correct its own processes more quickly than for product received from outside suppliers. It can verify that sanitary dressing and any interventions are being applied consistently as designed; it can implement corrective actions when it identifies that sanitary dressing procedures and any interventions have not been applied as designed; and it can identify and correct underlying problems that result in any repeated sanitary dressing or intervention failures. Figure 13 below shows the direct knowledge the slaughter establishment has concerning the production of in-house source materials during the slaughter process. Figure 13 If an establishment identifies problems in its own slaughter operations, for example, that sanitary dressing was not consistently implemented, it can consider how this problem may impact food safety decision-making during further processing. Similarly, if an establishment identifies problems during further processing, for example, that ground", "56 poultry sampling identified that a lot exceeded acceptable pathogen levels, the establishment can identify whether factors at slaughter may have contributed to the problem. Incoming Source Materials from Supplying Establishments Establishments have less knowledge available about and control over source materials that are produced at other supplying establishments. However, there are a number of actions that establishments receiving raw poultry for further processing can take to limit Salmonella in their incoming source materials. All establishments receiving raw poultry from supplying slaughter establishments can require the supplier to follow good sanitary dressing procedures to prevent contamination of poultry during slaughter. In addition, establishments can consider requiring that incoming raw materials be treated with interventions shown to reduce Salmonella. Establishments could also require that suppliers test source materials for pathogens of concern and have a plan for how to use test results in their decision-making. Establishments receiving source materials from outside suppliers can consider implementing the above requirements as purchase specifications and incorporating such specifications in their HACCP plans, Sanitation SOPs, or other prerequisite programs. If establishments producing raw poultry products require their suppliers

(both within and outside their corporate structure) to meet purchase specifications, they can also ensure that their suppliers actually meet these purchase specifications. They may accomplish this in several ways, by requiring, for example: \u2022 a document (e.g., letter of guarantee (LOG)) from each supplier that provides assurance that the supplier employs CCPs or other control points that address Salmonella and that describes the CCP, the monitoring of the CCP, and the use of any interventions; and \u2022 certificates of analysis (COAs) (i.e., actual test results) and the sampling method used by the supplier of the source material. A further processing establishment receiving source materials can maintain records (e.g., its own testing results, ongoing communication with suppliers, or third-party audits) that verify on an on-going basis that the supplier is executing its program in a consistent and effective manner. Ongoing verification ensures that the receiving establishment consistently receives product in which Salmonella is prevented or controlled to acceptable levels. Establishments that receive source materials from outside suppliers can still consider applying validated interventions during further processing. Approved interventions are listed in the FSIS Directive 7120.1 lookup table along with any required parameters for each entry. Such establishments can also consider carrying out their own testing of Key Point As part of the entire HACCP system, food safety decisions made at slaughter impact further processing, regardless of where further processing occurs.", "57 incoming source materials. As described in the Sampling and Testing section, testing can measure the pathogen load of incoming source material so that establishments can ensure that their processes are not overwhelmed by the incoming pathogen load. In addition, they can consider testing finished products to verify their systems reduce pathogens to acceptable levels. An establishment may be able to obtain detailed information concerning the purchased\incoming source material on a lot-by-lot basis (preferably, lots are defined as being microbiologically independent) from its supplier. In this situation, the receiving establishment may be able to support that Salmonella is NRTL at receiving based on the implementation of a prerequisite program (e.g., purchase specifications) that prevents the potential hazard from becoming RLTO. Such establishments that address pathogens in this manner can do the following: \u2022 have a written program that describes the purchase specifications that it will implement to show that pathogens are NRTL at receiving; \u2022 require information (for example, through letters of guarantee) on the supplying establishment\u2019s interventions that provide assurance that the supplier uses interventions that address pathogens, such as Salmonella; \u2022 obtain certificates of analysis (COA) affirming that source materials have been tested (with results available at purchase). If a receiving establishment is unable to obtain COAs, the establishment can obtain other evidence that each shipment or lot of purchased\incoming source materials was tested. In these situations, establishments can: o be aware of the sampling and testing method the supplier uses, and o be aware of the supplying company\u2019s information concerning the specific product codes that were sampled and tested.", "58 Figure 14 below shows the knowledge of the source materials\u2019 production that the receiving establishment is able to obtain by having a relationship with its suppliers. Figure 14 It is possible that a receiving establishment is not able to obtain detailed information concerning the purchased product\u2019s production on a lot-by-lot basis from its supplier. When a receiving establishment is only able to obtain general information concerning the production of purchased\incoming source materials, the establishment must take other measures to support its hazard analysis decision-making (9 CFR 417.5(a)(1)) at receiving in

order to justify the conclusion that pathogens are NRLTO. These measures may include, but are not limited to, the following options: 1. The receiving establishment may determine that pathogens such as Salmonella are RLTO on incoming source materials and apply an antimicrobial treatment as a part of their HACCP system. 2. The receiving establishment may be able to support that Salmonella are NRLTO in incoming source materials at receiving based on the implementation of a prerequisite program (e.g., antimicrobial treatment preventive measures on incoming raw materials) that prevents the potential hazard from becoming RLTO during its process, including rigorous recordkeeping documentation. For this situation, establishments can do the following: o have a written program that describes the antimicrobial treatment preventive measures that it will implement to show that Salmonella are NRLTO at receiving; o maintain supporting documentation for the program;" "59 o maintain records that demonstrate that the program is being implemented as written (i.e., verification records of the critical operating parameters); o maintain records that provide on-going evidence that the program effectively reduces pathogens to acceptable levels (e.g., its own verification testing) to support its decision that pathogens such as Salmonella are NRLTO at receiving; and o describe actions that the establishment will take when it fails to implement the program, or when it otherwise finds that the program has failed to prevent the hazard. Note that for option 2, if establishments determine that Salmonella are hazards NRLTO because of prerequisite programs, they are required to have records associated with their Sanitation SOP or other prerequisite programs that show these programs are preventing a food safety hazard from being RLTO as part of their HACCP decision making documents. When prerequisite programs are not effectively designed or consistently implemented, the hazard analysis is not supported, and FSIS would consider the hazard to be reasonably likely to occur. In this case, establishments must then take corrective actions (including reassessment) as set forth in 9 CFR 417.3(b). 3. The receiving establishment may be able to support that pathogens including Salmonella are NRLTO in the purchased source materials at receiving based on the implementation of its own verification testing measures in conjunction with purchase specifications that require information on the supplying establishment\u2019s interventions that provide assurance that the supplier employs CCPs that address pathogens such as Salmonella. Sanitation and Reducing Cross-Contamination Poultry carcasses processed as parts or used to make ground products have a higher incidence of pathogens because of possible cross contamination between positive and negative parts and carcasses during further processing. The sanitation considerations discussed in the Sanitation section also apply to further processing operations. This section discusses factors that establishments producing parts or comminuted poultry can consider to maintain sanitation and minimize cross-contamination during further processing. Opportunities for cross-contamination during further processing exist in various situations. One situation is when products are commingled (for example, parts are collected in combo bins for further processing). Another situation when pathogen spread and cross-contamination may occur is during parts cut-up or during the grinding (or other comminuting) process, specifically when skin is cut, ground, or otherwise Key Point Salmonella can be found inside feather follicles in the skin. When skin is cut, these pathogens can be exposed and spread during processing to previously uncontaminated product." "60 broken. Salmonella can be found in feather follicles in the skin (Kim et al 1996; Wu et al., 2014). These areas may not be accessible until they are disturbed, for example during cut-up or grinding, when these processes can result in exposure

of and spread of pathogens. National prevalence data from FSIS\u2019s Chicken Parts Baseline sampling indicate that skin-on parts were more likely to be positive for Salmonella than parts without skin (FSIS, 2014). Opportunities for cross-contamination also occur following the heat treatment step during production of raw but heat-treated poultry (for example, NRTE breaded, stuffed poultry products). For these products, it is essential that the finished product be processed in a manner to reduce the frequency and level of contamination before packaging at the establishment (e.g., by controlling cross-contamination between the time when products emerge from the hot oil or other batter-setting process until they are in final packaging). Approaches may include aseptic handling (gloves, sterile implements), designated clean spaces or containment to prevent exposure to contamination after the heat treatment. Handling of these types of products by the consumer may contribute to cross contamination in the home. Cross contamination can also occur anytime that raw poultry products are produced in one part of an establishment and further processed in another part. How product containers are handled within an establishment can increase cross contamination. Figure 15 shows tub containers used to hold poultry parts for further processing. The tubs were stored on dirty pallets, and employees touched the bottoms of the tubs when they emptied their contents into a hopper before using their gloved hands to push the contents into the hopper. Not only does this practice result in cross contamination, it is also an example of an insanitary practice.",<sup>61</sup> Figure 15 Not recommended: Plastic tubs used to hold raw poultry parts are stacked on wooden pallets, which are moved to another area in the establishment for further processing. Establishment employees picked up the tubs and frequently touched the bottoms of the tubs when emptying them into the hopper. Then, without first sanitizing their gloves, employees pushed the parts into the hopper. This is an example of both cross contamination and not maintaining operational sanitation.",<sup>62</sup> Product contact surfaces such as belts, augers, paddles, knives, hooks, and other implements can be regularly cleaned and sanitized to reduce cross contamination during operations. Figures 16a and 16b show that sanitary conditions during further processing are not being maintained due to buildup of organic material. Figure 16a Not recommended: Sanitary operation is not being maintained. There is significant buildup of fat and other organic material on the belts. This presents an increased risk of cross contamination. Figure 16b Not recommended: Sanitary operation is not being maintained. There is a significant buildup of fat and other organic material on the conveyors, blades, and associated product contact surfaces. This presents an increased risk of cross contamination. Establishments can keep in mind that the finished poultry products they produce that go for further processing at other establishments may be used to produce non-intact products such as those that are injected, tenderized, or vacuum tumbled. Finished",<sup>63</sup> poultry products may also be used as source materials for comminuted products, such as ground, mechanically separated, or similarly processed products, including patties and sausages. Because processes used to manufacture such products may increase the risk of cross-contamination and pathogen spread, establishments producing poultry parts for further processing can minimize opportunities for cross-contamination and consider whether the use of additional interventions for such products may prevent or reduce pathogens to acceptable levels. Establishments can also consider how their lotting practices can be designed to minimize cross-contamination. Achieving microbiological independence between lots can also limit product that may be implicated in a recall associated with an outbreak. Additional considerations for Non-intact

parts and products (mechanically tenderized, injected, or vacuum tumbled) Mechanical tenderization, such as needle and blade tenderization, injection with solutions, and vacuum tumbling are methods that some establishments use to tenderize products, add flavor, or add ingredients to raw poultry parts and carcasses. However, these processes can contribute to cross-contamination with pathogens. Any contamination on the outside of carcasses or parts may be carried to the inside through penetration by needles and other devices. Reusing injection solutions, such as brines or marinades, also presents risk for contamination of the solution by pathogens. A prime example of this mechanism of internalizing pathogens is an outbreak of Escherichia coli O157:H7 in beef steaks that occurred in 2007 (FSIS, 2007).

Contamination can also occur through introduction of contaminated liquid that is injected or forced into the muscle by injecting or vacuum tumbling. Contamination may be increased the longer solutions are reused and the greater the volume of product treated. Establishments should consider the effects of injected solutions in its hazard analysis (9 CFR 417.2(a)) and Recommended Best Practices, Sanitation and Reducing Cross Contamination 1. Clean product contact surfaces, including knives, as often as required to maintain sanitation during operations. 2. Knives and other tools can be sanitized between each carcass. 3. Consider using an antimicrobial intervention on parts. Key Points Blades and needles can push outside contamination into the interior of muscle. Injection solution picks up bacteria from contaminated product. Reused injection solution can push high levels of bacteria into the interior of muscle. The longer injection solution is reused, the greater the contamination.", "64 support all decisions made in the hazard analysis, 9 CFR 417.5(a)(1). Establishments that choose to tenderize, inject, or vacuum tumble raw poultry should consider the following factors: Operational sanitation should be maintained during the process, including evaluating the frequency that needles need to be replaced to minimize product residue buildup on the inside of the needle, which can be very difficult to remove. Establishments should consider the microbiological impact of introducing pathogens mechanically (through needles and blades) and by reusing a solution. Any solution reuse should be addressed in the HACCP plan or in the Sanitation SOP or another prerequisite program. Risk from microbial pathogens introduced during non-intact processes may be reduced in several ways: \u2022 by limiting this process to products that will undergo a lethality treatment at another federally inspected establishment \u2022 applying antimicrobial interventions to product just prior to treatment with needles or blades \u2022 limiting the time that solution is reused and maintaining a solution temperature of less than or equal to 40 \u00b0F (4.4 \u00b0C) to prevent pathogen outgrowth \u2022 treating reused solution with interventions to minimize or eliminate pathogens. Ultraviolet (UV) light treatment (Beers et al., 2010) can reduce pathogens in recirculated brine. Establishments can also consider how any solution reuse affects the establishment's lot designation.

Recommended Best Practices, Sanitation During Production of Non-Intact Products 1. Consider applying antimicrobial interventions to products prior to tenderizing or injecting. 2. Do not reuse injection needles if product residue cannot be removed. 3. Limit reusing injection solution to poultry that will receive a lethality treatment. 4. Establishments that choose to reuse injection solution can consider adding antimicrobial processing aids to the solution and can limit the time it is reused prior to sanitizing the injection system.", "65 Additional considerations for comminuted products Producers of comminuted poultry products can also consider that because of the fine texture of these products, meat and protein residues of these products may

extend into very small or unexpected food contact surfaces in grinding and other equipment. In addition to the factors already discussed, establishments that make comminuted poultry products can consider the information in this section with regard to minimizing microbial pathogens and creating and maintaining sanitary conditions. Surfaces of processing equipment, including grinders, blenders, pipes, and other components and surfaces in contact with the product require focused attention to ensure adequacy of sanitation procedures. These surfaces may include hoppers, augers, blades, grates, product blenders, and patty makers.

Establishments can consider parts of equipment that can harbor bacteria, such as rubber gaskets and similar pieces that may be difficult to reach and sanitize and ensure that they are sanitized when other surfaces are. The fine texture of comminuted product and the processes used to make them create a situation where one contaminated component can spread contamination into multiple batches of product. Systematic sanitizing of belts and other implements can break the chain of any contamination that slips through. Rather than the contaminant being spread across lots, it will be stopped or at least diminished. Different source materials used to produce comminuted products can present different risks of pathogen contamination. Establishments can consider the information below when making processing decisions for comminuted products. Source Materials Can Affect Pathogen Status of Comminuted Product Certain poultry parts may be more likely to be contaminated with pathogens and are therefore riskier to use as source materials to produce comminuted poultry products. The FSIS Chicken Parts Baseline study (FSIS, 2013) found that chicken necks were significantly more likely to be contaminated with Salmonella (55%) than other parts, including breasts, legs, and wings (between 20-44%). Establishments can consider not using chicken necks in comminuted poultry products or only using them in comminuted products that are intended for a lethality treatment. Similarly, skin-on and bone-in source materials used in comminuted chicken products present increased risk of contamination with Salmonella. As previously discussed, skin can contain Salmonella in feather follicles that can be exposed during the grinding or other comminuting process and spread throughout a lot. Chicken neck skin has Key Point Contaminated source materials going into a grinder, mechanical separator, or other comminuted poultry equipment can result in contamination of all product until the next cleaning and sanitizing is performed.", "66 typically been found to be more contaminated than other parts of the carcass. Research by Wu et al. (2014) concluded that neck skin included in ground chicken presents a significant risk for the introduction of pathogens. Table 4 shows that ground and other raw comminuted chicken products (such as sausages and patties) sampled by FSIS that were produced using either bone-in or skin-on source materials were more likely to be contaminated with Salmonella4 than those fabricated from deboned, skinless source materials. Table 5 shows the risk for use of bone-in source materials for comminuted turkey products.

Table 4. FSIS exploratory sampling testing results, raw comminuted chicken by source material composition (6\1\13-6\30\15, 2,688 samples) The interior of poultry bones can contain pathogens as well. In a recent study, 0.8% of chicken bones sampled were positive for Salmonella (Wu et al., 2014). In a different study, 5.2% of turkey bones sampled were positive for Salmonella (Cui et al., 2014). Although these may appear to be low percentages, again because of the nature of comminuted processes, contamination can spread throughout an entire batch or lot from a few contaminated bones through cross contamination. FSIS sampling data indicate that both chicken and turkey raw comminuted products produced using bone-in

source materials are more likely to be contaminated with Salmonella than those 4 FSIS Not Ready-to-Eat Comminuted Poultry Exploratory Sampling Project results from samples collected June 1, 2013 through June 30, 2015. For bone-in and skin-on source materials, Salmonella prevalence in comminuted chicken was 56.0%. The lowest prevalence product, made from deboned and skinless source materials, was 34.8%. To calculate the relative risk, each source material type was divided by the lowest risk product:  $56.0 / 34.8 = 1.6$ . Comminuted Chicken Products Salmonella prevalence in this source material Salmonella presence risk relative to the lowest prevalence source material (Deboned & skinless)5 Mechanically separated 83.4% 2.4-fold increase Ground and Other Comminuted Chicken Products Salmonella prevalence in this source material Salmonella presence risk relative to the lowest prevalence source material (Deboned & skinless) Bone-in & Skin-on 56.0% 1.6 Bone-in & Skinless 58.4% 1.7 Deboned & Skin-on 54.8% 1.6 Deboned & Skinless 34.8% N/A", "67 produced using deboned source materials. Table 4 shows this for comminuted chicken products, and Table 5 shows this for comminuted turkey products. Tables 4 and 5 indicate pathogen prevalence for comminuted products based on whether source material contained bone (chicken and turkey) or skin (chicken only). Analysis of FSIS comminuted poultry sampling results shows that it is more likely that comminuted chicken will be positive for Salmonella when its source materials contain bone, skin, or both bone and skin (58.4, 54.8, and 56.0%, respectively). Comminuted chicken made from deboned and skinless source materials had the lowest prevalence for both pathogens (34.8%). The tables also indicate how much more likely products made from different source materials are to contain pathogens, as compared to the product with lowest prevalence (products made from deboned and skinless source materials). Raw comminuted chicken products made from bone-in and skin-on source materials were 1.6-1.7 times more likely to be positive for Salmonella compared to those made from deboned and skinless source materials.4 Mechanically separated poultry product nearly always contains skin and bones in their source materials, because of the nature of the processing of this product. FSIS sampling results indicate for comminuted chicken, Salmonella prevalence was highest for mechanically separated poultry. For this reason, establishments can consider not using mechanically separated poultry as a component in NRTE comminuted products, or only using it in comminuted products that are intended for a lethality treatment. Table 5. FSIS exploratory sampling testing results, raw comminuted turkey by source material composition (6/1/13-6/30/15, 934 samples) Comminuted Turkey Products Salmonella prevalence in this source material Salmonella presence risk relative to the lowest prevalence source material (Deboned) Mechanically separated 52.4% 1.4-fold increase Ground and Other Comminuted Turkey Products Salmonella prevalence in this source material Salmonella presence risk relative to the lowest prevalence source material (Deboned) Bone-in 56.8% 1.5 Deboned 37.7% N/A It is important to keep in mind that the data in Tables 4 and 5 represents FSIS data from all establishments sampled in the exploratory program, without consideration of the amount of skin or bone going into comminuted processes. Each individual", "68 establishment can determine the extent that skin-on and bone-in source materials may contribute to pathogens in finished product. This determination can be made by sampling and testing comminuted products made from different source materials. Establishments that do not test products by source material can consider the information provided in the tables during decision-making in their processes. Using the information in the prevalence column of the tables, establishments

can compare the relative risk of using different types of source materials. For example, in the absence of its own sampling results, an establishment can compare using bone-in and skin-on source materials (56.0% Salmonella prevalence) with using deboned and skinless source materials (34.8%) to determine that the relative risk is 1.61 (56/34.8). This means there is about a one and a half times greater chance that the bone-in, skin-on source material will result in Salmonella being present in the finished product. Therefore, there is likely a benefit to using the deboned skinless source materials instead of the bone-in, skin-on source materials.

**Interventions** Unless otherwise stated, interventions (antimicrobial processing aids) described in this section have been reviewed for safety and suitability and are listed in FSIS Directive 7120.1. Establishments, intervention manufacturers, and other users that would like to implement interventions not listed in FSIS Directive 7120.1 would need to submit for review a protocol to FSIS describing the proposed function of the substance in the specific poultry or meat product and conditions of use, as described in the Intervention Use section.

Establishments may consider using interventions during further processing to decrease pathogens. Antimicrobial interventions may be applied to source materials prior to further processing, to parts, during grinding or other comminuting process, and during blending of ground or comminuted products. Establishments should consider all applicable labeling requirements when choosing an antimicrobial, in particular when adding aqueous solutions to products with a standard of identity that does not allow added water (e.g., \u201cgroun chicken\u201d; 9 CFR 319.15(a)). High pressure pasteurization (HPP) is another intervention that may be applied to raw comminuted product. Although applying interventions to source materials used in comminuted products can reduce pathogens in finished product, contamination may still occur during the process itself when skin or bones are broken, releasing bacteria that were not exposed to the antimicrobial application. Establishments can consider these factors when evaluating their use of interventions. Establishments can evaluate the adequacy of any Salmonella interventions they apply to parts during further processing, including those source materials that are specifically intended for non-intact use (such as grinding or other comminuted processes). Part of the evaluation can include consideration of variability of Salmonella levels on source materials. The same considerations discussed in the general Interventions section apply to selecting and applying interventions during further processing. Those", "69 considerations also apply to parts that are sent to other establishments for any kind of further processing because they may be used as source materials in comminuted or otherwise non-intact raw product. Interventions to control Salmonella can be applied by spraying or dipping (immersion). Generally, immersion is more effective than spraying because it ensures better coverage and longer contact time (Buncic & Sofos, 2012; McKee, 2014). Loretz et al. (2010) reported that acetic acid (20 ppm at 4\u00b0C) resulted in a Salmonella log reduction (log CFU) of 1.4 when applied as a dip (immersion), compared to a log reduction of 0.8 when applied as a spray. A potential challenge with immersion is maintaining the proper level of active chemical as it becomes absorbed and neutralized by organic material such as fat and protein. Another challenge with immersion is maintaining the active concentration of the intervention despite the natural decomposition of the compound as a result of chemical reactions, heat, or light. It is important to verify with sufficient frequency that the critical operational parameters of an antimicrobial dip are maintained. It may be necessary to either add more chemical or even to completely change the solution to maintain effectiveness. Figure

17 shows an antimicrobial dip being applied to boneless, skinless poultry parts prior to grinding. Figure 17 Best practice: Boneless, skinless poultry parts receive an antimicrobial dip prior to being ground. The following pages present information on some antimicrobial interventions that may be used during further processing and which have been studied to control pathogens during further processing. This information is summarized in the attachment to this guideline. Establishments need to adhere to the limits in the conditions of use for chemicals as described in FSIS Directive 7120.1 and 9 CFR 424.21. In addition, the establishment", "70 needs to determine the optimum concentration for its process based on the critical operational parameters in its scientific support documentation. Any ranges for pH, concentration, or other parameters included in this section are provided to give a general indication of these values, but they do not represent critical operational parameters. Inorganic and Organic Chlorine-based Treatments Chlorine is relatively inexpensive, has a broad spectrum of activity, and is quick acting. Its drawbacks include corrosiveness to processing equipment at low pH, loss of effectiveness at higher pH values, loss of effectiveness with increasing organic matter load, and longer contact time required as compared to some other antimicrobial interventions.

Commonly used chlorine compounds include liquid chlorine, hypochlorites, inorganic chloramines, and organic chloramines. Chlorine is typically used at pH 6.0 \u2013 7.5. A number of chlorine entries for use with poultry are in the FSIS Directive 7120.1 lookup table along with their acceptable uses. Chlorine added to water produces free available chlorine in the forms of hypochlorous acid and hypochlorite ions. Hypochlorous acid is the form most lethal to microorganisms. Acidified sodium chlorite Acidified sodium chlorite (ASC) is a type of chlorine compound that is a strong oxidizer. It enters bacterial cells and weakens or kills them by lowering the pH inside. ASC is safe and suitable for use on poultry carcasses and parts at concentrations of 500-1200 ppm, as indicated in FSIS Directive 7120.1. It is used at pH 2.3-2.7 and acidified with an organic acid, such as lactic acid, citric acid, or acetic acid. A benefit of ASC is that it is not as highly affected by the presence of organic material as chlorine. Mehyar et al. (2005) reported a 1.1 log reduction in *Salmonella* on inoculated drumsticks when treated with ASC. Recommended Best Practices, Interventions during Further Processing 1. Applying antimicrobial interventions during further processing can be part of an effective multiple hurdle approach to reducing pathogens. 2. Dipping is generally a better application method than spraying as it ensures full coverage of an intervention for a longer period of time.", "71

Trisodium Phosphate Trisodium phosphate (TSP) is an inorganic, non-chlorine-containing compound with a high pH. Its pH is 11-13 and is used at concentrations of 8-12%. A benefit of high pH is that it gives TSP detergent-like activity, which can improve effectiveness against microorganisms. The main disadvantage of using TSP is disposal, as the high discharge of phosphate into the sewer may be a violation of local, state, or federal Environmental Protection Agency sewer discharge regulations. Quaternary Ammonium Compounds Quaternary ammonium compounds (QAC) are a group of positively charged organic compounds that may have detergent-like properties (Schmidt, 2012). Most have a high pH (pH 6-10), are used at concentrations \u22641%, and are effective in killing a wide variety of microbes.

Cetylpyridinium chloride (CPC) is an example of a QAC. CPC is an odorless, colorless, stable compound that does not self-decompose and is not affected by organic material. QACs persist in solution for a relatively long time. QACs are not compatible with soaps, anionic detergents, or low pH solutions. CPC must be rinsed off poultry after use with water containing no more

than 50 ppm chlorine. The major disadvantage of QAC is that some may be less effective in hard water that contains >500 mg/L hardness (Miller, 2012). Organic Acids and Organic Oxidizers  
Organic acids and organic oxidizers used at the proper pH are effective in being able to enter bacteria to inhibit or kill them from the inside. Peroxyacetic acid (PAA) is an organic oxidizer. It has been studied on poultry parts to control pathogens. PAA is a mixture of the peroxy compound, hydrogen peroxide, and acetic acid. It is a versatile compound, as different formulations are available that may be used over a wide temperature range (0 to 40°C) and wide pH range (3 to 7.5). PAA is affected by protein or other organic materials to a lesser degree than chlorine is (Bauermeister et al., 2008). Studies comparing chemical interventions In one study, Del Rio (2007) evaluated acidified sodium chlorite (ASC), trisodium phosphate (TSP), citric acid, and peroxyacids (PAA) against Salmonella on chicken legs. The concentrations used were: ASC 1200 ppm with citric acid added until pH 2.7 was reached (final pH 2.70); TSP 12% (final pH 13.03); and peroxyacids 200 ppm (Inspexx 100, Ecolab, St. Paul, MN; final pH 3.75). The temperature of the disinfection solution at use was 18°C. Chicken legs containing approximately 9 log CFU/ml Salmonella were dipped in the disinfection solutions for 15 minutes and drained at 20°C for 15 minutes. The number of bacteria killed was then measured. All treatments", "72 resulted in Salmonella reduction, with ASC and TSP having greater effectiveness than PAA (log reduction of 2.05, 1.86, and 0.93, respectively). In another study (Chen et al., 2014), researchers treated Salmonella inoculated chicken parts (bone-in and skin-on) with chlorine, PAA, and cetylpyridinium chloride (CPC) at various concentrations in a chilled immersion system for 25 sec. PAA and CPC significantly reduced Salmonella in a dose-dependent manner. Water and chlorine had little effect in reducing Salmonella. A study by McKee et al. (2013) compared the pathogen reduction of antimicrobial interventions applied to chicken parts, including those used to produce ground product. Chicken parts were treated with different concentrations (0.35% and 0.60%) of cetylpyridinium chloride (CPC), (0.07% and 0.10%) peracetic acid (PAA), and (0.003%) chlorine in a parts decontamination tank. Preliminary research shows that parts immersed/dipped into PAA had the greatest reductions of Salmonella followed by CPC. Chlorine was the least effective. However, this lack of effect may be related to short contact times (<20 sec) for chlorine. Findings from this study suggest that dips/immersions are more effective than single spray systems when treating parts because of their longer contact times and complete coverage. Bacteriophages Bacteriophages (also called phages) are naturally occurring organisms (viruses) that infect only a specific host bacterium (Hagens & Loessner, 2010). Phages cannot infect humans (Lu & Breidt, 2015). Phages are ubiquitous in the environment in the water, in soil, and on food consumed (Guenther, 2009). Once phages infect bacteria, they can multiply inside of the bacteria, destroy the cell wall of the bacteria, and then be released into the environment where they can infect other susceptible bacteria. Several phage applications demonstrated to infect Salmonella are listed in Directive 7120.1 for use with poultry. The phage application researched by Sukumaran, et al. (2015) was on chicken skin and skinless chicken breast filets. The study combined a 20 second dip at 4°C in organic antimicrobial compounds followed by a spray application of anti-Salmonella phage (108109 PFU/g). The organic antimicrobial compounds tested were: cetylpyridinium chloride (CPC) at 0.6%; lauric arginate (also known as lauramide arginine ethyl ester; LAE) at 200 ppm; and peroxyacetic acid (PAA) at 50 and 400 ppm. Chicken skin treated in this manner achieved the following Salmonella reductions: CPC, 2.1 log reduction; LAE, 2.4 log

reduction; PAA (50 ppm), 1.7 log reduction; and PAA (400 ppm), 0.9 log reduction. Skinless chicken breast treated in this manner achieved the following Salmonella reductions: CPC, 2.2 log reduction and LAE, 2.6 log reduction (the PAA dip was not studied on skinless chicken breast).", "73 Physical Interventions Electrolyzed Oxidizing Water Treatment Electrolyzed oxidizing (EO) water is inexpensive, must be generated on-site with specialized equipment, has strong bacterial killing effect, and has little residual (longlasting) effect. EO water is acidic and is an effective antimicrobial immersion\dip solution (Northcutt et al., 2007). However, it usually requires much longer contact time than other interventions, so spraying may not be an appropriate application method. EO water is produced by passing direct current voltage through a dilute sodium chloride (salt) solution. The result of the reaction is the production of two types of water (Hsu, 2005). It is the EO water that has low pH (2.3-2.7), high oxidation-reduction potential (>1000 mV), and high dissolved oxygen. A high oxidation-reduction potential means that more oxidation will occur. That translates to a greater capacity to form free radicals that kill bacteria (Venkitanarayanan, 1999). Huang (2008) and Hsu (2005) provide detailed descriptions on the concepts. The production of EO water containing sodium chloride (1-12% w\% v) results in the formation of sodium hypochlorite (NaOCl) and hypochlorous acid (HOCl). HOCl functions as if chlorine gas was added into the poultry parts disinfection solution without the need to store a dangerous gas. It is important to point out that although EO water is strongly acidic, it is different from strong acids, such as hydrochloric acid or sulfuric acid, in that it is not corrosive to skin, to mucous membranes in the nose and lungs, or to poultry carcasses or parts (Huang, 2008). However, the HOCl (sodium hypochlorite) generated by the EO process may cause breathing irritation that can be reduced with proper ventilation (Huang, 2008). High Pressure Inactivation A typical high pressure pasteurization (HPP) system consists of a pressure vessel, pressure transmission fluid (usually water), and pressure generating pumps. HPP is a technology by which a product is treated at a very high pressure. HPP requires specialized equipment and is usually applied off-site where that equipment is located. HPP treatment kills or inhibits microorganisms, and researchers have studied its effectiveness in reducing pathogens in comminuted chicken and chicken parts. An advantage of using HPP is that surviving microorganisms can be more sensitive to other types of antimicrobial interventions as compared to bacteria that have not been exposed to HPP (Alpas, 2000). Escriu (2009) treated finely minced chicken inoculated with 6 log CFU\g Salmonella with HPP at 400 MPa at 20\u00b0C for 2 min with a water-oil mixture used as the pressure transmission fluid. Salmonella was reduced 3.26 to 4.35 log CFU\g.", "74 Tananuwong (2012) applied HPP to chicken breast inoculated with Salmonella (7 log CFU\g) at 300 MPa at 35\u00b0C for 1 min and achieved approximately 2 log reduction. Irradiation using Ionizing Radiation Food irradiation is the process of exposing food to high levels of radiant energy and is applied by directing ionizing radiation to food products. Food can be irradiated commercially for several purposes: to extend shelf-life, eliminate insect pests, or reduce numbers of pathogenic microorganisms. Ionizing radiation can penetrate deeply into food, killing insect pests and microorganisms without raising the temperature of the food significantly (Jaczynski, 2003). Ionizing radiation kills bacterial cells and pests by damaging DNA (Tahergorabi, 2012; Verma, 2001). Ionizing radiation results from cobalt-60, cesium-137, x-rays, and electron beams. Cobalt-60 (60Co) is a common source of a form of ionizing radiation called gamma irradiation. It has high penetrating power (Ahn, 2013), which allows the treatment of poultry of variable sizes,

shapes, and densities (including frozen and unfrozen). X-rays are also used to produce ionizing radiation. X-rays have high penetrating power but are typically not used for treatment of food because it is not an efficient process (Tahergorabi, 2012). Another way of producing ionizing radiation is by applying an electron beam (e-beam). In this approach, a stream of high-energy electrons is applied to products. Because the radiation penetrates only a few centimeters, it is useful to treat thin layers of food (Jaczynski, 2003; Ahn, 2013). The electron beam may be applied over moving food on a conveyor, unlike some other sources of ionizing radiation. Electron beam systems require regular maintenance, high electric power, and cooling as the equipment produces high heat (Ahn, 2013). The maximum dosage of ionizing radiation is 3 kGy absorbed by raw poultry (fresh and frozen). The maximum dosage limit allowed for poultry is based on the safety determination that was made by FDA (21 CFR 179.26(b)(6)). A requirement that FDA placed on the use of irradiation is that the packaging of irradiated poultry must be air permeable and does exclude moisture and microorganisms from penetrating the package barrier. To promote processing flexibility and innovation that will lead to improvements in food safety, FSIS does not specify at which point irradiation may or may not be applied. Under HACCP, an establishment must control the conditions under which product is held from initial processing through irradiation and packaging to ensure and preserve the intended antimicrobial effects of irradiation (64 FR 72150)6. FSIS requires the labeling of irradiated meat and poultry products, including the radura symbol. These labeling requirements are outlined in the final rule, Irradiation of Meat Food Products, 64 FR 72150. 6 Irradiation of Meat Food Products; Final rule. Dec 21, 1999. Federal Register. 64: 72150-72166.","75 Thayer (1991) used gamma irradiation at 0 to 3.6 kGy on sterile, mechanically deboned chicken meat inoculated with approximately log 9.9 cfu/g Salmonella Typhimurium. In this study, the higher the dose of gamma radiation used, the higher the kill rates of Salmonella (log reductions). Gamma irradiation was also more lethal for S. Typhimurium at higher temperatures and in the presence of air (as opposed to in a vacuum). The researchers found that using gamma irradiation resulted in a log reduction between 5.5-7 log. More details of the conditions used to achieve these log reductions are available in the research article. In a different study, Thayer (1992) inoculated fresh, nonfrozen chicken wings with Salmonella Typhimurium and used five gamma irradiation doses: (0, 0.90, 1.80, 2.70, and 3.60 kGy) in air at 5\u00b0C. All Salmonella were killed on samples inoculated with 10 or 100 CFU/wing. Surviving Salmonella were detected on chicken wings inoculated with either 1,000 or 10,000 CFU/wing after irradiation with 1.8 kGy, but the numbers were very low (below enumeration limit). No Salmonella were detected following gamma radiation doses of 2.7 or 3.6 kGy. This study demonstrated that irradiating poultry could result in significant reductions in Salmonella on raw chicken wings. Another study found that applying electron beam irradiation to boneless, skinless chicken breasts containing naturally occurring bacteria resulted in an approximately 5log reduction in Salmonella and Campylobacter. The doses applied were 1.0 and 1.8 kGy at ambient temperature and both doses resulted in comparable reduction of Salmonella and Campylobacter (Lewis 2002).","76 References Ahn DU, Kim IS, and Lee EJ. 2013. Preface This is a revised version of the FSIS Guideline for Controlling Salmonella and Campylobacter in Raw Poultry. This is the 2021 edition of the FSIS Guideline for Controlling Campylobacter in Raw Poultry. This edition separates the guideline into two separate documents in response to comments received on the 2015 edition: one for Salmonella and one for Campylobacter. This guideline represents FSIS\u2019 current thinking on these topics and should be considered usable as of its issuance. The information in this guideline is provided to assist poultry slaughter and processing establishments in controlling hazards and meeting the FSIS pathogen performance standards. The contents of this document do not have the force and effect of law and are not meant to bind the public in any way. This document is intended only to provide clarity to the public regarding existing requirements under the regulations. Under the regulations, establishments may choose to implement different procedures than those outlined in this guideline, but they would need to validate and support how those procedures are effective. This guideline is focused on small and very small establishments in support of the Small Business Administration\u2019s initiative to provide small businesses with compliance assistance under the Small Business Regulatory Enforcement Fairness Act (SBREFA). However, all poultry establishments may apply the recommendations in this guideline. It is important that small and very small establishments have access to a full range of scientific and technical support, and the assistance needed to establish safe and effective Hazard Analysis Critical Control Point (HACCP) systems. FSIS has other guidance documents availabe for establishments that slaughter and process raw poultry products, including: \u2022 Information about the chilling of poultry products can be found in the Modernization of Poultry Slaughter Inspection: Amendments to Chilling Requirements. \u2022 Information about designing and implementing a microbiological sampling plan can be found in the FSIS Compliance Guideline: Modernization	

of Poultry Slaughter Inspection - Microbiological Sampling of Raw Poultry. \u2022 Information about controlling Campylobacter and Salmonella in chicken liver can be found in the FSIS Guideline: Chicken Liver. \u2022 Information about controlling Salmonella can be found in the FSIS Guideline for Controlling Salmonella in Raw Poultry." , "4 Congressional Review Act Pursuant to the Congressional Review Act at 5 U.S.C. 801 et seq., the Office of Information and Regulatory Affairs has determined that this guideline is not a \u201cmajor rule,\u201d as defined by 5 U.S.C. 804(2). Reason for Issuing the Guideline FSIS revised this guideline to respond to public comments on the Draft Compliance Guideline For Controlling Salmonella and Campylobacter in Raw Poultry (4th Edition) and provide updated information for establishments to use to control pathogens in raw poultry products with the goal of reducing human illnesses from consuming poultry contaminated with Campylobacter. In addition, since the 2015 revision of this guideline, FSIS has implemented the more sensitive enrichment method for Campylobacter and is therefore revising Campylobacter pathogen performance standards for chicken parts, comminuted chicken and turkey products. This guideline can assist establishments in meeting Campylobacter performance standards and reducing illnesses associated with Campylobacter. CDC estimates Campylobacter is the #1 cause of bacterial diarrheal illness in the United States; most Campylobacter infections are associated with eating raw or undercooked poultry or from contamination of other foods by these items (CDC, 2017). This guideline describes concerns and controls for each step in the poultry slaughter process. The interventions suggested in this guideline cannot overcome poor preharvest production practices, poor sanitary practices in slaughter and dressing, or poor slaughter and further processing facility sanitation. Establishments can use this guideline to improve management practices, make changes at the appropriate locations, and improve process control. As a result, establishments can produce raw poultry products at a higher standard of pathogen control, including Campylobacter. Again, the information in this guideline is provided as guidance to assist poultry slaughter and processing establishments and is not legally binding from a regulatory perspective. Changes from the Previous Version of the Guideline This guideline is final. FSIS will update this guideline as necessary when new information becomes available." , "5 FSIS made the following specific changes to the guideline to reflect the peer-reviewed literature and address public comments received on the Draft Compliance Guideline For Controlling Salmonella and Campylobacter in Raw Poultry (4th Edition): \u2022 Removed the word \u201ccompliance\u201d from the document title and throughout the document to clarify that this document does not constitute regulatory requirements; \u2022 Separated information specific to controlling Campylobacter into a separate guideline; \u2022 Removed redundant language related to other current FSIS guidelines, providing hyperlinks to those resources where appropriate; \u2022 Added relevant, current peer-reviewed science related to poultry slaughter and processing, including a complete revision of the bedding and litter section, and additional literature resources specific to Campylobacter; \u2022 Added information about antimicrobial carryover and considerations to mitigate its effect on microbiological sampling; and \u2022 Updated data tables outlining the relative risk of various source materials used in further processed poultry products based on recent FSIS data. How to Effectively Use the Guideline This guideline is organized to provide users with the current science and recommendations. To use this guideline, FSIS recommends that readers use the navigation headings to move efficiently through the document sections of interest. Hyperlinks, where

provided, will quickly take you to the correct place in the document electronically and are also provided to other complementary documents. The reference list at the end of the document provides resource material used in the development of this guidance (References). Questions Regarding Topics in this Guideline If after reading this guideline you still have questions, FSIS recommends searching the publicly posted Knowledge Articles (\u201cPublic Q&As\u201d) in the askFSIS database. If after searching the database, you still have questions, refer them to the Office of Policy and Program Development through askFSIS and select \u201cSampling\u201d as the Inquiry Type or by telephone at 1-800-233-3935.","6 Documenting these questions helps FSIS improve and refine present and future versions of the guideline and associated issuances. Background FSIS regulated poultry slaughter and processing establishments are required to determine the \u201cfood safety hazards that can occur before, during, and after entry into the establishment\u201d (9 CFR 417.2(a)) in their hazard analysis. Pre-harvest interventions, adequate sanitary dressing procedures at slaughter, and adequate sanitary conditions during further processing are a part of an integrated approach to reduce the public health impact of *Campylobacter*. This pathogen is a hazard that establishments producing raw poultry products can control through a Hazard Analysis and Critical Control Point (HACCP) plan or prevent in the processing environment through Sanitation Standard Operating Procedures (Sanitation SOPs) or other prerequisite programs. FSIS has determined that contamination of poultry carcasses and parts by fecal material and enteric pathogens (including *Campylobacter*) is a hazard reasonably likely to occur (RLTO) in poultry slaughter establishments unless addressed in a Sanitation SOP or other prerequisite program.<sup>1</sup> For this reason, if an establishment relies on its Sanitation SOP or other prerequisite program to address enteric pathogens, the establishment\u2019s HACCP system must identify why such Sanitation SOP or other prerequisite program results in the enteric pathogens being not reasonably likely to occur (NRLTO). The measures outlined in this document will be most effective at decreasing *Campylobacter* in raw poultry products when considered together. Food Safety and the HACCP Framework Unlike the production of ready-to-eat (RTE) product in which a lethality treatment destroys pathogens of public health concern, slaughter and further processing operations do not have as many available treatment options capable of destroying all pathogens in raw products. Under HACCP regulations, establishments are required to have a system designed to ensure that poultry is processed in a manner that prevents and controls potential contamination hazards that are RLTO during slaughter and processing. Slaughter establishments can have controls and procedures in place to reduce the level of incoming contamination on the exterior of the birds and to reduce or mitigate any contamination that can occur throughout the slaughter process. 1 79 FR 49565 (p.49613) Key Point Federally inspected poultry establishments are required to conduct a hazard analysis as part of their Hazard Analysis and Critical Control Point (HACCP) system. The hazard analysis is required to include \u201cfood safety hazards that can occur before, during, and after entry into the establishment\u201d (9 CFR 417.2(a)).","7 Establishments must document the controls and procedures they use to reduce contamination in their HACCP plan, Sanitation SOP, or applicable prerequisite program in accordance with 9 CFR 417.5. HACCP Plan to Control Hazards If the establishment decides through its hazard analysis that *Campylobacter* is a food safety hazard that is RLTO, 9 CFR 417.2 requires that the establishment\u2019s HACCP plan address this food safety hazard. The HACCP plan must meet all parts of 9 CFR 417.2(c), including having a critical control point (CCP) to address the pathogen. A CCP is defined as a point, step, or

procedure in a food process at which control can be applied, and, as a result, a food safety hazard can be prevented, eliminated, or reduced to acceptable levels. As an example, an establishment might have a CCP at a point during slaughter for applying a validated antimicrobial intervention to carcasses. FSIS requires the establishment to develop critical limits (CLs) for CCPs to control hazards that are RLTO (9 CFR 417.2(c)(3)). CLs are the parameters that indicate whether the control measure at the CCP is in or out of control. A critical limit is the maximum or minimum value to which a physical, biological, or chemical hazard must be controlled at a critical control point to prevent, eliminate, or reduce to an acceptable level the occurrence of the identified food safety hazard (9 CFR 417.1). An example of CLs are the critical operational parameters for an antimicrobial intervention applied to carcasses at a point during slaughter. For example, critical operational parameters of an antimicrobial applied with a spray bar may include concentration, pH, and spray pressure. To determine whether CLs are being met, establishments must monitor them (9 CFR 417.2(c)(4)). Monitoring is a planned sequence of observations or measurements to assess whether a CCP is under control and to produce an accurate record for future use in verification. Monitoring procedures usually involve either a measurement or an observation. For the example of a CCP of applying an antimicrobial intervention during slaughter, monitoring activities might include measuring the concentration, pH, and other critical limits of the antimicrobial intervention, at a frequency sufficient to determine whether the CCP is under control. If a CL is not met, the establishment must meet the corrective action requirements in 9 CFR 417.3. To document whether the establishment meets its CCP, the establishment records its measurements and corrective actions as part of a recordkeeping system. Verification ensures that the HACCP plan is being implemented as written and confirms the accurate monitoring of the CCPs. Guidance on validation and ongoing verification is available in the FSIS HACCP Systems Validation guideline.", "8 GENERAL CONSIDERATIONS More general considerations, including information on sanitation, sampling, hazard analysis, scheduled slaughter, and HACCP, relative to controlling pathogens during poultry production are covered in the FSIS Guideline for Controlling Salmonella in Raw Poultry. These principles apply to both the control of Salmonella and Campylobacter. Additional sampling guidance is available in The FSIS Compliance Guideline: Modernization of Poultry Slaughter Inspection - Microbiological Sampling of Raw Poultry. Using Microbiological Sampling and Testing Use of Microbiological Sampling Data Following successful validation of its HACCP system, an establishment uses the validation data to implement its system. Establishments are required to support the monitoring and verification procedures selected and the frequency of those procedures (9 CFR 417.5(a)(2)). Microbiological verification data ideally includes samples collected at a number of points throughout the process (e.g., samples of starting materials, interim product, and finished product) for the same lot. Selecting samples in this way allows the establishment to determine whether the HACCP system is reducing contamination, and whether the HACCP system is working as designed, similar to process mapping. Samples at intermediate points provide additional information about intermediate process steps. Target Organisms Establishments can consider the advantages and disadvantages of testing for the presence of selected indicator bacteria and pathogens for ongoing HACCP verification. Sampling and testing costs for indicator species may be lower than costs for pathogens. However, while elevated levels of indicator bacteria are usually interpreted to mean pathogens are more likely, this relationship is not perfect. In other words, high levels of indicator organisms do not always

mean that the pathogen is present, and low levels do not guarantee the pathogen is controlled. Only pathogen testing can effectively verify that pathogens are controlled to acceptable levels in finished product. *Campylobacter* is not captured by commonly used indicator tests, including Aerobic Plate Count (APC) and Enterobacteriaceae (EB). There are no identified indicator organisms that directly reflect the presence or absence of pathogens in poultry (e.g., *Campylobacter*). Therefore, FSIS recommends that an establishment test for pathogens at least intermittently and compare its results against the presence or absence of other non-pathogenic organisms (i.e., the indicator organisms the establishment is using) to assess whether it is maintaining process control. For example, an establishment could consider the FSIS "minimum number to", "9 assess" for each FSIS performance standard as a guide to ensure that they collect enough data points to have statistical confidence in their pathogen percent positive. For most products, that is roughly one *Campylobacter* sample per month (for example, 11 samples/52 weeks for comminuted poultry). This approach is supportable if the analytical method has comparable sensitivity to the FSIS method; the less sensitive the method, the more samples are needed to increase confidence in the accuracy of the results. The indicator organisms can provide evidence of control, while periodic testing for pathogens may verify that the establishment is reducing pathogens to acceptable levels. Establishments conducting their own ongoing verification sampling and testing of finished product for *Campylobacter* can use the FSIS performance standards as indicators of process control. Sample Collection Method Proper sample collection techniques and procedures are necessary to ensure the accuracy of test results. Sample handling and collection procedures are specific to the type of product to be sampled (e.g., parts or comminuted), the sample collection method (e.g., parts rinse, comminuted product sampling), and the type of sample collected (e.g., rinsate sample, finished product samples, excision sample of skin). Individuals who will collect samples need to receive training on proper sample collection procedures. It is important for the establishment to be able to collect and ship samples properly. Onsite assistance or information on proper sample collection (aseptic techniques) and prompt shipment of samples to the laboratory from the establishment are also important. The final result of the analysis will be neither accurate nor meaningful if a laboratory has not implemented procedures to prevent mishandling of samples or alteration of records. In particular, *Campylobacter* is sensitive to light (Ultraviolet exposure) and freezing, so it is critical that samples are maintained in a refrigerated, but not frozen, place until shipped or transported to the laboratory. Maintaining temperature of the sample above 0 °C but below 15 °C before and during transport protects sample integrity. To effectively use data to evaluate process control, the collection, handling, storage, and transportation of samples must be carefully controlled to prevent temperature abuse, sample leakage, and other events that could affect sample integrity and lead to unreliable test results. Procedures for maintaining sample integrity are particularly important when samples need to be transported from the establishment to an off-site laboratory (e.g., by a delivery service such as FedEx or courier) where they may not be under the direct control of the establishment or the laboratory for a period of time. Examples of non-destructive sample collection techniques that an establishment may choose to use to collect poultry carcass samples are included as attachments to the FSIS Compliance Guideline: Modernization of Poultry Slaughter Inspection - Microbiological Sampling of Raw Poultry. Non-destructive techniques do not result in", "10 destruction of the product being sampled. A parts rinse sample

collection is an example of a non-destructive sampling technique. Antimicrobial Interventions and Drip Time Using antimicrobial interventions during processing steps may make it more difficult to detect remaining bacteria, particularly when non-destructive or surface sampling is conducted. For destructive sampling, in which the tissue itself is collected for analysis at the laboratory, remaining antimicrobials will continue to be inactivated by organic material in the sample during shipment of the sample to the laboratory. Conversely, with rinsate or through other surface sampling, capturing the antimicrobial in a buffer or other sampling solution may prolong the antimicrobial's effective time. For example, consider poultry carcasses exiting a chiller tank where antimicrobial interventions are used. Contaminated carcasses may have bacteria that survived the chiller tank. However, those bacteria may not be detected through sampling if the carcass is not allowed adequate drip time before the establishment collects a rinse sample. Adequate drip time will allow excess antimicrobials to drip off the carcass. Immediate sample collection will include a significant amount of residual antimicrobials, which suspended in rinsate will remain active and make it harder for the laboratory to detect live bacteria. If the carcass is allowed adequate drip time, the sample will contain less residual antimicrobials, and the laboratory will be more likely to detect live bacteria. At this time, FSIS generally recommends establishments wait at least 60 seconds after application of antimicrobial interventions before collecting a sample to reduce the amount of antimicrobial carryover. A longer drip time may be recommended by the antimicrobial manufacturer for particular solutions. Tipping over the carcass to allow drainage of chiller water that has accumulated in the body cavity can also result in greater accuracy of the test result. Establishments could consider whether a neutralizing agent is available which could stop the action of any residual antimicrobial intervention, making it possible to more accurately detect live bacteria remaining on the sample. Examples of a neutralizing agent suited for particular antimicrobials would include lecithin for Cetylpyridinium Chloride (CPC), sodium thiosulfate for Peroxyacetic Acid (PAA), or sodium thiosulfate plus bicarbonate for Acidified Sodium Chlorite (ASC) (Gamble et al., 2016). Recommended Best Practices, Ongoing Verification Testing 1. Prevent samples being analyzed for *Campylobacter* from exposure to freezing temperatures and Ultraviolet light exposure. 2. Both indicator bacteria and pathogens can provide useful information. 3. Allow at least 60 seconds before sampling after application of any antimicrobials, to prevent excessive antimicrobial carryover in the collected sample.", "11 PRE-HARVEST Pre-Harvest Interventions and Management Practices Pre-harvest interventions and practices can prevent or reduce *Campylobacter* contamination in live birds, increasing the effectiveness of post-slaughter interventions and establishment controls. This section identifies available pre-harvest interventions\practices, and how slaughter and processing establishments can encourage their use by poultry producers. This section covers poultry production from breeder stock through transport to the slaughter establishment. Live receiving and subsequent slaughter steps are covered in the following section. Food Safety Hazards Colonization of the poultry gastrointestinal tract with *Campylobacter* is a food safety hazard that can occur at pre-harvest (i.e., at grow-out, the hatchery, or at the breeder farm). Colonization can then result in fecal shedding of bacteria, which can contaminate skin and feathers during many steps from breeder farm to arrival at the slaughter establishment. External contamination can also occur during slaughter from rupture of the gastrointestinal tract and transfer of pathogens on contaminated equipment. FSISregulated establishments can,

as part of their overall HACCP system, address these hazards through purchase specifications or other agreements to require that their suppliers implement certain pre-harvest management controls. Pre-Harvest Interventions & Management Practices FSIS recommends that establishments use two main practices for managing preharvest colonization of poultry with *Campylobacter*. Together, these practices are expected to reduce the number of birds colonized with or shedding pathogens, reduce the number of these pathogens in colonized birds, and reduce the likelihood that contamination will be transferred from colonized to uncolonized birds. First, FSIS recommends that slaughter establishments receive birds from grow-out farms, hatcheries, and breeder flocks that implement the recognized pre-harvest interventions described in this section. Implementing these interventions can decrease *Campylobacter* contamination on birds received by slaughter and processing establishments (Cox & Pavic, 2010). Establishments may include specifications in their grow-out contracts for growers to incorporate strategies that address the potential contamination of *Campylobacter* during hatching and grow-out. Reducing or eliminating *Campylobacter* on incoming birds at slaughter establishments can reduce contamination of finished products and increase the likelihood that the establishment will meet FSIS performance standards for *Campylobacter*. Alternately, if an establishment does not require *Campylobacter* to be addressed at preharvest, FSIS recommends that slaughter and processing establishments test incoming", "12 birds and poultry products before entry into the establishment and make processing decisions based on those test results. By using these test results, an establishment could decide to implement a scheduled slaughter and processing plan based on the presence or absence (\u201cstatus\u201d) of *Campylobacter* (Katsma et al., 2007) as described in the FSIS Guideline for Controlling *Salmonella* in Raw Poultry. Other decisions could be to utilize additional chemical interventions or divert products from positive flocks to lethality treatment (such as cooking). Pre-harvest Recommendations to Control *Campylobacter* FSIS recommends that official establishments obtain birds produced from a system of breeder flocks, hatcheries, and grow-out houses that use the pre-harvest best practices and interventions described here. This section provides information on interventions intended to prevent the exposure of birds to pathogens and on available products intended to reduce the incidence or level of *Campylobacter* contamination in birds. Interventions to prevent exposure and colonization in live birds are typically more effective than products that treat birds exposed to *Campylobacter* to reduce incidence or levels, as it is more difficult to eliminate *Campylobacter* from colonized flocks. There are numerous routes of exposure to *Campylobacter* during pre-harvest including: \u2022 Exposure to contaminated water, feed, and bedding in the grow-out house; and \u2022 Environmental exposures due to poor biosecurity practices and inadequate pest control. Vertical transmission of *Campylobacter* (transmission via the egg from hen to chick) is not as well documented as that of *Salmonella*; however, contamination of the egg during laying by a colonized hen can lead to exposure during hatching, transferring the pathogen from parent to progeny (Cox et al., 2012). FSIS is not aware of a single pre-harvest intervention that eliminates *Campylobacter* as a pre-harvest hazard. Instead, FSIS recommends that a \u201cmulti-hurdle\u201d approach be employed; this means that multiple sequential pathogen interventions are used that can have an additive effect to reduce pathogens. Implementing multiple interventions and controls beginning at pre-harvest extends the multi-hurdle approach to *Campylobacter* prevention and control across each bird\u2019s life. Using interventions with

differing modes of action can further improve the extent of pathogen reduction when using a multi-hurdle approach. In this Guideline, FSIS is providing available effectiveness data for preharvest interventions, as identified in scientific literature. However, because many factors during the pre-harvest period can contribute to pathogen colonization of individual birds, the spread of pathogens between birds in a flock, and the excretion of Key Points Interventions to prevent exposure and colonization in live birds are preferable as it is more difficult to eliminate *Campylobacter* from flocks once infected. Preventive interventions in live birds lose effectiveness if the flock is already infected. Consider using multiple interventions throughout preharvest." "13 pathogens by birds, use of a particular intervention may have different efficacy than specified. Thus, the concept of a multi-hurdle approach is important to keep in mind.

Establishments can consider requiring suppliers to use the interventions listed here.

Establishments can use these pre-harvest controls as part of their HACCP system (through purchase specifications or other agreements) and to support their decisionmaking. FSIS will work with other federal agencies such as USDA-Animal and Plant Health Inspection Service (APHIS), the Food and Drug Administration (FDA), and USDA-Agricultural Research Service (ARS), to develop additional information on preharvest interventions. This Guideline breaks the pre-harvest interventions into six categories focused on physical, biological, and hygienic approaches to reduce pre-harvest exposure to *Campylobacter*: Breeder Flock & Hatchery, Grow-out House, Bedding, Feed, Water, and Transportation. Scheduled Slaughter is an additional approach, which is covered in the FSIS Guideline for Controlling *Salmonella* in Raw Poultry. When considering the control of hazards on incoming birds, slaughter establishments can consider exposurereducing interventions combined with one or more of the products available for preharvest control to reduce incidence or levels of *Campylobacter* in poultry that may be exposed to this pathogen (Table 1). These products have different modes of action, but all produce the same result: reduced incidence of pathogen colonization and reduced pathogen levels in colonized birds. Efficacy depends on the specific product, and most are used in consultation with a veterinarian. Using both types of pre-harvest approaches \u2014 those to reduce exposure and those that reduce incidence of colonization and levels of pathogens \u2014 will minimize pathogens on birds at harvest. Using the interventions and best practices recommended in this guideline can help to provide for animal welfare and bird health at pre-harvest, thereby reducing stress in live poultry and reducing *Campylobacter* in birds presented at slaughter. Evidence suggests that stress at pre-harvest can have adverse effects on food safety (Corry, 2001). Understanding the mechanism by which stress alters normal intestinal characteristics and induces susceptibility to enteric infections, may help in developing additional pre-harvest strategies to reduce pathogen contamination in poultry. NOTE: In this section, the term \u201cyoung chickens\u201d refers to all chickens raised for slaughter to distinguish it from chicken breeder stock. The term here is not limited to \u201cbroilers\u201d as defined in 9 CFR 381.170(a)(1)(iii). In this section, \u201cyoung turkeys\u201d refers to all turkeys raised for slaughter to distinguish it from turkey breeder stock. Table 1. Pre-harvest products to reduce colonization and number (level) of *Campylobacter* in poultry. Definition Notes on Use Vaccines: increase immunity to *Campylobacter* by exposing the immune Several vaccines are currently in development for the prevention of *Campylobacter* in live poultry. Proposed targets include the flagellar antigens as well as the", "14 system to a controlled preparation. Vaccine types include live vaccines (an attenuated strain of *Campylobacter*), sub-

unit vaccines (a vaccine with minimal parts of the target for immune response), and autogenous vaccines (developed from bacteria isolated from the farm environment). capsule of the bacteria (Poly et al., 2019). Special approvals from APHIS are required for long-term use of autogenous vaccines or for use of these vaccines with multiple flocks. Competitive Exclusion & Probiotics: preparations of beneficial bacteria that compete with *Campylobacter* in the gut for space or nutrients. Also known as direct-fed microbials. Some products can be used on the day of hatch to establish healthy gut flora in chicks. Other products can be added to water and feed for both breeders and young chickens and used to boost competition against pathogens throughout the bird's lifetime or when otherwise indicated (e.g., stress). One study on the effectiveness of a competitive exclusion culture in poultry found a statistically significant reduction in colonization and shedding of *Campylobacter* (Smialek et al, 2018). Prebiotics: specific nutrients that will allow beneficial bacterial species to more effectively compete against *Campylobacter*. Can be added to the feed of both breeders and young chickens. The most common supplements include yeast extracts, such as beta-glucans and mannan oligosaccharides. A study on the effectiveness of a prebiotic in poultry found that some available prebiotics reduced *Campylobacter* by more than 1 log, and when combined with probiotics, reduced *Campylobacter* by more than 3 logs (Kim et al, 2019). Organic Acids: increase the acidity of the gut, which can kill *Campylobacter*. Because each bacterial species has a different susceptibility to organic acids, this mechanism also increases the ability of beneficial bacteria to compete against pathogens. Can be added to both feed and water for breeders and young chickens. Adding to water during feed withdrawal is particularly important. After feed is withdrawn, birds may be more likely to peck at litter and may ingest pathogens. Organic acids in the water will lower the pH in the crop and reduce pathogen colonization and growth. One study found that use of lauric acid products resulted in up to a 1 log reduction of *Campylobacter* (Zieger, 2017).<sup>15</sup> Breeder Flock & Hatchery Breeder flocks and hatcheries can be the original source of *Campylobacter* colonization for young chickens because infection can be transmitted through the egg (vertical transmission). Establishments can obtain broiler and turkey chicks from breeder flocks and hatcheries that follow National Poultry Improvement Plan (NPIP) procedures and recommendations. The NPIP was established in the early 1930's to provide a cooperative industry, state, and federal program through which new diagnostic technology can be effectively applied to the improvement of poultry and poultry products throughout the country. Because of the possibility of vertical transmission, establishment parent companies and independent growers can consider placing broiler and turkey chicks from breeder flocks free of *Campylobacter* onto grow-out farms (Cox et al., 2012). (Note that pathogen-free breeder stock is not a requirement for participation in NPIP.) Broiler breeders also demonstrate variability in innate immunity to *Campylobacter*<sup>14</sup> some chicken breeder stocks have been shown to be more resistant to colonization (Han et al., 2016; Connell et al., 2012). Utilization of these parental breeding stocks can produce broiler chicks that are more resistant to on-farm colonization. Consider the use of one or more of the products listed in Table 1 to prevent or reduce colonization by *Campylobacter* in live birds that are destined for slaughter. Several of the probiotic, prebiotic, and organic acid products can be administered to both breeder flocks and young chickens, often through feed and water. Competitive exclusion and probiotics can be administered to chicks on the day of hatch to inoculate the gastrointestinal tract with beneficial bacteria (Table 1). Inoculation with beneficial bacteria at the hatchery can be followed with use

of appropriate prebiotics and organic acids at the grow-out house to maintain beneficial bacteria through growout. Chicks can be transported from the hatchery to the grow-out house in new or cleaned\sanitized, and ideally lined, containers (Cox & Pavic, 2010). Limit the number of individuals handling the chicks from the truck to the interior of the grow-out house to minimize chances for exposure. Recommended Best Practices, Breeder Flock and Hatchery 1. Obtain chicks from pathogen-free breeder flocks and from breeders and hatcheries following NPIP procedures. 2. Use breeding stock with innate resistance to Campylobacter. 3. Consider using one or more of the products listed in Table 1. 4. Transport chicks to grow-out in new or sanitized containers.", "16 Although the following sections focus on young chickens and turkeys, the best practices identified also apply to chicken and turkey breeders and can serve to minimize pathogens in these flocks. Grow-out Houses Farms and houses can be designed to facilitate cleaning and disinfection between flocks (Cox & Pavic, 2010). All poultry farms can develop and implement written biosecurity and hygiene plans. Poultry health is best monitored under the supervision of a veterinarian. Available research suggests that the following practices are correlated with a decreased likelihood of Campylobacter in birds presented for slaughter (Cox & Pavic 2010; Newell et al., 2011; Muenier et al., 2017): \u2022 Housing a single species (e.g., only chickens or only turkeys) on the farm; \u2022 Keeping birds of different ages in different houses; \u2022 Limiting the number of people with access to grow-out houses and using disinfecting boot dips or disposable foot coverings and disposable coveralls when entering the house (a study by Gibbens et al. (2001) found that correct use of a boot dip and house-specific boots and overalls reduced flock colonization of Campylobacter by 50%); \u2022 Removing vegetation around buildings, installing screens on windows and other openings, and increasing physical integrity of buildings to prevent access by rodents, birds, or insects; and \u2022 Using pest control measures including bait and traps.", "17 In addition to reducing exposure to Campylobacter with the measures described above, consider the use of one or more of the products in Table 1 to reduce colonization and the incidence or level of pathogens in exposed birds. Most probiotics, prebiotics, and organic acids can be used with both breeder and broiler flocks as feed or water additives. Biologics, including vaccines and antibody products, are licensed for use by USDA-APHIS, which updates the complete listing on their webpage. Live vaccines may introduce the target pathogen into flocks presented for slaughter; the establishment can consider this possibility and develop their HACCP plan and sampling programs accordingly. Bedding Litter or bedding can be considered a reservoir for Campylobacter contamination (Montrose et al., Shane, Harrington, 1985). Downtime between flocks is ideally around 10 -14 days which allows moisture removal and desiccation of litter. Ensure that no new moisture is added and that wet caked areas are removed during the litter turn over (fluff). There are technologies that allow composting or windrowing of litter between flocks (Malone & Johnson, 2011; Wilkinson et al., 2011; Macklin et al., 2008). It is important to note that litter is not uniform in moisture, organic carbon availability, pH, or microbial populations, which are all factors that can influence pathogen destruction or growth in litter during and following composting. Water activity (Aw) and pH of the litter are positively correlated with pathogen growth (Terzich, 2000). Consider chemical treatment of the litter to reduce pH and Aw during production to reduce pathogen growth and contamination of the flock, which could reduce pathogen recovery at the processing establishment. Recommended Best Practices, Grow-out House 1. Implement on-farm biosecurity and hygiene plans, 2.

Minimize the number of people with access to the grow-out house. 3. Require the use of disposable foot coverings or boot dips. 4. Consider the use of products in Table 1. Key Points Pre-harvest interventions must not: 1) Negatively impact product safety, 2) Jeopardize the safety of Federal inspection program personnel, 3) Interfere with inspection procedures, including FSIS sampling, or 4) Conflict with the Agency's regulations.","18 Litter treatments to reduce pH are commonly added prior to flock placement because the early grow-out phase (~1st week for young chickens, ~ 3 weeks for turkeys) is when the birds are most susceptible to pathogen colonization (Han, 2016). Several chemical additives have been used to decrease the pH of poultry litter, such as aluminum sulfate (Moore & Miller, 1994; Line, 2002;), ferrous sulfate (Huff et al., 1984), phosphoric acid (Reece et al., 1979), sodium bisulfate (Moore et al., 1996) (Terzich, 1997), and acetic acid (Parkhurst et al., 1974). Reducing litter pH to less than 4.5 can reduce *Campylobacter* to below detectable limits (Line, 2002). Since litter pH increases to near neutral after the first week of production, reapplication of the litter treatment may be needed (Pope & Cherry, 2000). During grow-out, moisture in the house can be controlled with the use of tunnel ventilation systems. If the moisture in the litter is too high (as observed in the winter months due to decreased ventilation), *Campylobacter* colonization of birds from contaminated litter can increase. Wet litter can also be caused by environmental conditions (rain, poor drainage, leaky roofs), evaporative cooling systems, excess drinking, health problems, panting, excess bird density, and watering systems such as type of waterers (bell, trough, nipple), leaky valves, maladjusted waterers, too many birds per drinker, or broken water lines. Feed Select growers that use feed that is free of *Campylobacter*. Specifically, obtain feed from manufacturers that follow Good Manufacturing Practices (GMPs) to reduce or eliminate pathogens, such as those certified by the Safe Feed/Safe Food program administered by the American Feed Industry Association. Safe Feed/Safe Food producers may also conduct finished product testing to verify the product is negative of certain hazards. Clean and disinfect feeders between flocks and keep feeders in good repair. Consider adopting the use of feed additives that are effective in young chickens (Table 1). Protect feed from contamination during transportation and storage. Transport the feed to the farm in accordance with the FDA's Sanitary Transportation of Human and Animal Food final rule (81 FR 20091), which includes provisions for cleaning transportation vehicles before transport of feed and measures to prevent contamination or tampering of feed during transportation. Store feed on-farm in a manner that reduces the Recommended Best Practices, Bedding 1. Use a litter treatment to reduce litter pH < 4 and Aw < 0.84. 2. Use a composting or windrow treatment during flock downtime. 3. Allow 10-14 days between flocks to desiccate litter and verify destruction of pathogens.","19 likelihood of contamination through contact with pests, fomites, or the environment (Hald et al., 2004). If feed is stored on-farm in a manner that could result in contamination (such as open bins or bags), poultry producers can conduct periodic sampling of the feed to determine whether contamination has occurred during storage. Some research indicates that pelleted feed is more resistant to contamination during storage than mash, and that the addition of organic acids to the feed may also protect against contamination. The Association of American Feed Control Officials (AAFCO) provides additional recommendations on the production and distribution of animal feed in its document titled '\u201cBest Management Practices for Manufacturing, Packaging & Distributing Animal Feeds and Feed Ingredients.\u201d Time feed withdrawal appropriately; withdrawal from feed can occur

between 8 \u2013 12 hours before slaughter (Cox & Pavic, 2010). Withdrawing feed before slaughter can ensure that birds have an empty gastrointestinal tract during transport, slaughter, and evisceration, which can reduce external contamination with fecal material. However, some research indicates that early withdrawal may lead the birds to peck at the litter in the grow-out house and decrease the acidity of the crop, increasing the likelihood that the bird will ingest pathogens and be contaminated at slaughter (Byrd et al., 1998). Consider providing water with organic acids (Table 1 and discussed below) during feed withdrawal to prevent colonization of the crop. Extended feed withdrawal may also make internal organs more fragile, increasing the likelihood that the crop or other organs will tear during processing and contaminate the carcass (Cox & Pavic, 2010). Most studies support a feed withdrawal period of 8-12 hours to prevent organ tearing (Cox & Pavic, 2010). Water Provide abundant, potable water (Cox & Pavic, 2010). If water is not from a chlorinated or municipal source, routine testing is recommended to ensure that the source is free of pathogens. Clean the water distribution system between flocks, ensuring that biofilms, which may be reservoirs for pathogens, are removed when possible. Ensure that the water system is free of cracks and leaks to minimize waste and to keep bedding dry. Recommended Best Practices, Feed 1. Clean feeders between flocks. 2. Use feed that is pathogen free. 3. Consider use of appropriate feed additives (Table 1). 4. Protect feed from contamination during transport and storage 5. Pelleted and acidified feed may be more resistant to contamination during storage. 6. Supply water with organic acids during feed withdrawal.", "20 A number of the products listed in Table 1 are available as water additives for young chickens. Of note are organic acids added to water, particularly during feed withdrawal (Byrd et al., 2001). Providing water during feed withdrawal distracts birds from pecking at the litter. Adding organic acids to this water source will increase the acidity of the crop, which can help protect the bird against any *Campylobacter* they may ingest when pecking at the litter.

Transportation The presence of *Campylobacter* on birds at receiving at slaughter has been linked to dirty transport cages (Slader, et al., 2002). Cross contamination of both birds and cages is frequently made worse when the birds are transported to the establishment. To prevent such contamination, transport birds in clean containers (Cox & Pavic 2010). Clean, single-use paper liners can be used when transporting chicks but are not recommended for transporting young chickens to slaughter. In all cases, clean and disinfect transportation cages between each load. Minimize the number of individuals involved in removing birds from the grow-out houses. Figure 1 shows a chicken transport crate that is not washed after every load.

Recommended Best Practices, Water 1. Provide abundant, potable water. 2. Clean water distribution systems between flocks. 3. Consider feed and water additives listed in Table 1, particularly organic acids during feed withdrawal.", "21 Recommended Best Practices, Transportation 1. Use clean containers and sanitize containers between loads. 2. Use new disposable paper liners when transporting chicks to the farm. 3. Minimize the number of individuals involved in transport. 4. Clean and disinfect transport crates between each load.

Figure 1 Not Recommended: Transport crate that is not washed with sufficient frequency. There is a buildup of fecal material and feathers that can contaminate subsequent flocks during transport. Using cleaned and disinfected transport cages for each load of birds is especially important after flocks have been sampled prior to harvest. This is because contamination from dirty cages can change the pathogen status of a flock from negative to positive and reduce the effectiveness of scheduled slaughter and processing decisions.", "22 SLAUGHTER AND

**PROCESSING Slaughter** This section of the guideline provides information for establishments that slaughter poultry. The diagram below presents the steps in poultry slaughter addressed in this section. How well an establishment conducts its slaughter dressing procedures has a direct bearing on whether the decontamination and antimicrobial intervention treatments in<sup>23</sup> place in a poultry operation will have their intended effects. When contamination overwhelms the decontamination efforts and antimicrobial intervention treatments, the establishment may need to take additional steps to reduce pathogens.

**Live Receiving and Live Hanging** Live receiving is the point in the slaughter process where poultry arrive at the establishment in transport crates or cages, are unloaded, and are hung on shackles. There is a potential for contamination with enteric pathogens, including *Campylobacter*. The feathers, skin, crop, colon, ceca, and cloaca of birds brought to slaughter are often highly contaminated with *Campylobacter* (Kotula and Pandya, 1995). As described in the previous section, transport cages have been found to be sources of cross contamination of pathogens onto live birds transported to slaughter. Cleaning followed by sanitation of the unloading and holding area is important. High levels of *Campylobacter* found on incoming birds can overwhelm establishment interventions. These levels are carried forward to the next steps of the slaughter process. Studies show links between *Campylobacter* at live receiving and later in the process (Fluckey, et al., 2003; Newell, et al., 2001). Establishments can consider how the frequency of cleaning transport cages might inform their lotting practices, since research has indicated *Campylobacter* positive birds were linked to dirty transport cages. If establishments lot product (to achieve microbiological independence) on a flock basis, they can clean and sanitize transport cages between each flock to maintain microbiological independence. Employee traffic patterns and air flow can be controlled to prevent cross contamination and reduce levels of *Campylobacter*. There can be positive airflow moving from inside to outside of the establishment. Standard operating procedures and training, including changing clothes and boots upon arrival, separate facilities for dirty versus clean employees, and restricting employee movement are measures that can be put in place. One study found employee clothing to be a source of contamination for birds relative to *Campylobacter* (Herman, et al., 2003). Most establishments keep detailed records of suppliers and slaughter schedules by lots to monitor output or yields of products. An establishment could use these records to correlate its own in-house testing programs to determine if there are suppliers that routinely deliver birds carrying a high microbial load. Addressing potential contamination sources with suppliers could lower the microbial level of incoming birds at receiving and thereby reduce microbial loads, particularly pathogens, in chilled carcasses.

**Key Points** The feathers, skin, crop, colon, ceca, and cloaca of birds brought to slaughter are often highly contaminated with *Campylobacter*. Transport cages are an important source of cross contamination of birds with *Campylobacter*.<sup>24</sup>

**Stunning and Bleeding** This is the point in the slaughter process where the bird is stunned, cut, and bled. Stunning methods render birds unconscious. The method of stunning may be electrical, mechanical, or chemical. Bleeding ensures death by slaughter and ensures that poultry have stopped breathing before going into the scalding bath (9 CFR 381.65(b)). Stunning reduces struggling and convulsions. However, wing flapping and quivering that may happen because of the electrical stunning can transfer bacterial pathogens from the inside to the outside of the bird and to nearby birds and equipment. Continuous Gas Stunning, or Controlled Atmospheric Stunning (CAS), is an additional available

stunning method that uses a combinations of gases (e.g., carbon dioxide, argon, and nitrogen) to stun the birds before they are hung on the line. Any stunning method must be monitored and controlled to ensure effectiveness. A study by Musgrove, et al., (1997) showed that *Campylobacter* increased in carcass rinses collected after stunning. Good feed withdrawal practices can greatly reduce this problem. By decreasing the amount of feces expressed, establishments can reduce fecal cross-contamination on the surface of the carcasses, in the scald tank, and on the feather removal equipment. This decreases the level of *Campylobacter* carried forward into the next steps. Figure 2 shows young chickens entering the stunner with minimal external fecal contamination. Recommended Best Practices - Live Receiving and Hanging 1. Control airflow and traffic patterns. 2. Provide SOP and employee training. 3. Schedule flocks for slaughter based on pathogen loads.", "25 Figure 2 Best practice: These young chickens show minimal fecal contamination on their feathers as they enter the stunner. These birds are calmly entering the stunner. Scalding Scalding prepares carcasses for defeathering by breaking down the proteins that hold the feathers in place and opening up the feather follicles. It is the point in the slaughter process where the carcasses are placed in hot water in order to facilitate feather removal and is the first location during processing where carcasses are exposed to a common bath, which can allow *Campylobacter* cells from positive carcasses to spread *Campylobacter* to negative carcasses. However, scalding can reduce levels of *Campylobacter* on the carcasses, since much of the dirt, litter, and feces on carcasses is removed at this step. *Campylobacter* contamination consistently decreases when scalding is well controlled (Slavik et al., 1994; Hinton et al, 2004). Scalder water that contains high concentrations of fecal material is a problem. Birds may come into slaughter facilities with excessive fecal material on the feathers, which gets washed off in the scalder water. Figure 3 shows an immersion scald tank with excessive fecal material contamination. Berrang and Dickens (2000) found  $3.80 \log_{10} \text{CFU/g}$  of *Campylobacter* in breast skin before entering the scald tank. *Campylobacter* may harbor in chicken skin, which may aid its survival through scalding (Lee et al., ", "26 1998). Bacteria present in the dirty water may be massaged into the skin and open feather follicles. Also, the organic material may be retained on the surface of the bird through evisceration and end up in the chiller, deactivating the chlorine and preventing disinfection. Scalding cannot overcome high numbers of pathogens carried forward from previous steps. To reduce this problem, a bird brush and washer used prior to the scalder can remove some of the incoming dirt and fecal material. There are two methods for scalding: \u2022 steam-spraying \u2022 immersion Steam spray systems work by applying a mixture of steam and air at a temperature and pressure designed to scald the surface of carcasses. Immersion scalding is carried out by placing the carcasses into a tank of hot water. Tanks are either single- or multistage. Immersion is more common than steam-spraying. However, under the right conditions, both methods can reduce *Campylobacter* on carcasses. Figure 3 Not recommended: Excessive fecal material is present in the scalder Several considerations can mitigate contamination at the scalding steps. Water flowing into the tank ideally moves through the system flowing against incoming carcasses. This flow creates a dirty-to-clean gradient. Carcasses moving through the tank are washed by ever-cleaner water. Multiple stage tanks create more opportunities to clean the carcasses (Cason, et al., 2000). High flow rates of water and adequate agitation dilute the dry matter and bacterial load in the tank (Cason, et al., 2001). The water pH is a key operational parameter to monitor. A higher, more alkaline pH (9.0 \u00b1

.2) is best for reducing Campylobacter in the water (Humphrey & Lanning, 1987).,""27 Making the pH more acidic (3-4) is also effective at decreasing levels of Campylobacter (Okrend, et al., 1986). Establishments can initially monitor the pH in scald tanks as frequently as necessary to determine the pH highs and lows occurring during operation. Once establishments are able to maintain a desirable pH, less monitoring is needed. Uric acid from poultry feces can reduce the pH from 8.4 to 6.0 in less than 2 hours (Humphrey, 1981). Organic matter in the tank acts as a buffer to maintain a more neutral pH (6-7). Campylobacter is most heat resistant at a pH of 7.0 (Humphrey & Lanning, 1987). Understanding water characteristics is an important aspect in poultry slaughter operations. The source (well or treated surface water or municipal water), hardness, mineral content, and pH influence the killing action of any antimicrobial chemicals that are added to the water, and water hardness may affect the ability of water to wash bacteria from the skin of carcasses during processing (Hinton & Holser, 2009). Poultry establishments using more than one water source might consider the potential effect of the water source on the chemicals used. FSIS Directive 7120.1 Safe and Suitable Ingredients used in the Production of Meat, Poultry, and Egg Products and 9 CFR 424.21 provide a list of approved chemicals that can be used in scalders. Additives to raise the pH during scald have shown to be effective at reducing Campylobacter (Berrang et al., 2006). Most U.S. poultry processors prefer a hard scald to a soft scald. A hard scald is a shorter scald time at higher temperatures compared to a soft scald. This approach allows better removal of the outer layer of skin (epidermis). The correct water temperature for the appropriate amount of time is important to prepare the carcasses for feather removal. The correct water temperature also reduces dressing defects. When the water temperature is too high, the carcasses become oily. This oiliness makes it easier for Campylobacter to stick to the surface of the skin. If the carcasses are overscalded, the meat may start to cook, and the carcasses may be marked unacceptable and rejected by FSIS inspectors for overscald per 9 CFR 381.92. If the temperature is too low, the tank becomes a breeding ground for bacteria. Campylobacter cannot grow at temperatures greater than 116.6 °F (47°C). Therefore, scalding temperatures higher than 116.6°F (47°C) can be sufficient to control Campylobacter growth. Table 2 shows common scalding times and temperatures for various classes of poultry. Key Points Scalding is an important step that can reduce levels of Campylobacter on the carcasses. Water pH should be monitored carefully. Scalding can be used as an intervention if pH is properly maintained in the scald tank.,""28 Table 2. Common Scalding Times and Temperatures Class of Poultry Time /seconds Temperature °F Temperature °C Broiler (hard scald) 30-75 138.2-147.2 59-64 Broiler (soft scald) 90-120 123.8-129.2 51-54 Turkey 50-125 138.2-145.4 59-63 While scalding above 116.6 °F (47 °C) controls Campylobacter growth and initiates inactivation, scalding at 132 °F (56 °C) reduced Campylobacter counts most effectively (Slavik et al.,1995). Some religious traditions forbid scalding. Under Kosher slaughter, carcasses are soaked in cold water to make feather removal easier. Establishments can consider this potential effect in deciding what sanitary practices they employ downstream because the high number of pathogens not reduced during scalding can be transferred to future steps in the slaughter process. Picking The feather removal process is designed to remove feathers and the uppermost layer of the skin before evisceration. Carcasses typically pass through rubber picking fingers that mechanically remove feathers from the carcass. Most establishments use a continuous process. However, batch (not continuous; done at specific, defined and limited

times) and manual processes are sometimes used in low-volume establishments. Good process controls at picking are critical. Cross-contamination of the carcasses with *Campylobacter* occurs during picking because of contact with contaminated rubber Recommended Best Practices \u2013 Scalding 1. Have water moving counter current to carcasses. 2. Have high flow rates of water with adequate agitation to dilute dry matter and bacteria. 3. Use multi-staged tanks. 4. Maintain water pH at either above or below the optimum pH for *Campylobacter* growth (6.5-7.5). 5. Use pre-scald brush systems to clean birds prior to scald tank. 6. Maintain hard scald temperatures of 132 \u00baF and above.","29 picking fingers and contaminated reuse water (Geornaras, et al., 1997, Wempe, et al., 1983). Fecal material is released when picking fingers agitate and rub the carcasses and can lead to cross-contamination with fecal material between the carcasses (Allen, et al., 2003). Several researchers have determined that levels of *Campylobacter* increase during this step (Berrang & Dickens, 2001). Regular equipment sanitation and maintenance are recommended to minimize crosscontamination when using either batch or continuous picking. Post-feather removal rinses for carcasses is ideally maintained at 160\u00b0 F. Chlorine, acetic acid, and hydrogen peroxide are types of chemical rinses used during defeathering. If birds are plucked manually, the establishment can prevent cross-contamination by keeping the picking area as clean as possible and preventing feather buildup. Establishments can apply washes or antimicrobial interventions post-picking. However, cut surfaces of hocks must not be washed until FSIS postmortem inspection is complete (9 CFR 381.76, Post-mortem inspection). Otherwise, pathological exudate could be removed or obscured and prevent detection of synovitis by inspectors. Water reuse is addressed in 9 CFR 416.2(g)(3). This regulation states that water, ice, and solutions may be reused for the same purpose if measures are taken to reduce physical, chemical, and microbiological contamination so as to prevent contamination or adulteration of product. An establishment is required to have data to support all decisions regarding reuse, including a decision that reuse will or will not cause adulteration (9 CFR 416.2(g)(2)). Recommended Best Practices \u2013 Picking 1. Prevent feather buildup on equipment. 2. Regular cleaning and maintenance of rubber picking fingers. 3. Ensure coverage of sanitizer on picking rails and equipment. 4. Use a post picking antimicrobial intervention rinse. 5. Scientifically support any water reuse plan. Key Points Good process control procedures at picking are critical and can reduce *Campylobacter*. Fecal material is released when picking fingers agitate and rub the carcasses and can lead to crosscontamination between the carcasses.","30 Evisceration Evisceration is the point in the process where removal of the internal organs, and any processing defects, from the poultry carcasses occurs in preparation for chilling. Evisceration includes multiple processes. It begins at the transfer point (i.e., re-hang) and ends when the carcass enters the chiller. It is the point in the slaughter process where the removal of the viscera (including the gastrointestinal tract and edible offal such as heart, liver, and gizzard) occurs by automated or manual means, along with any trim of processing defects from the poultry carcasses in preparation for chilling. If viscera are not handled properly, or if employee hygiene practices are not followed, an increase in microbial contamination can occur. Feed withdrawal practices affect process control at this step. For the evisceration process to work well, carcasses need to be placed on the shackles correctly and monitored as they move through the system. Blades are ideally kept sharpened, and attention given to routine and thorough cleaning. Figure 4 shows an automated opener system that utilizes replaceable blades that are cleaned between each carcass. Figure 4 Best

practice: Replaceable blades (middle of picture) are washed between each carcass (yellow arrows) to reduce cross contamination. Blades are replaced daily, which minimizes cross contamination as compared to blades that are replaced less often. Key Points Evisceration begins at rehang and ends when the carcass enters the chiller. Feed withdrawal practices affect process control throughout the evisceration step. For the evisceration processes to work efficiently, carcasses need to be placed on the shackles correctly and machinery needs to be adjusted to accommodate bird size.", "31 Keeping the equipment in good sanitary condition, free from intestinal contents and segments, is important for maintaining good process control. Figure 5 shows viscera that was caught in the machine as well as fat and tissue build up on breast plates and other surfaces that is not being sufficiently rinsed and cleaned between carcasses. These practices can lead to cross contamination. Figure 5 Not recommended: Viscera are stuck in machine and there is product build up on breast plates and bars around wings and legs (yellow arrows). Automated transfer (re-hang), rather than manual transfer, of carcasses between the defeathering and evisceration lines can reduce external surface cross-contamination. Equipment used throughout the evisceration process can be installed, adjustments made, and machine performance calibrated effectively to handle the size, shape, gender, feed digestion capability, and live average weights of the birds to be slaughtered. These considerations apply to manual evisceration processes as well. Figure 6 shows a manual venting gun that is rinsed with chlorinated water between each carcass. Processing flocks with varying weight ranges can result in evisceration machinery performing poorly. Inconsistent carcass sizes (for example, because of poor bird size uniformity within a grower house or processing male and female birds together) can result in mis-cuts and fecal contamination. If machines are set for the median weight of the flock, poultry carcasses that are heavier or lighter may not be properly eviscerated. If carcasses are lighter or heavier than the machines can accommodate, the carcasses are more likely to have their gastrointestinal (GI) tracts split open, resulting in contamination of both carcasses and equipment. The machines need to be maintained in optimum condition and be properly aligned. Failure to maintain eviscerators in optimum condition can result in damaged intestines leading to carcass contamination.", "32 Equipment such as crop removal devices can easily become contaminated with *Campylobacter*, causing carcasses to later become cross contaminated. In some operations, at least half of carcass surfaces are contaminated with crop and upper GI contents immediately before evisceration (Byrd et al., 2002). Retracting the viscera from the body cavity can transfer crop and upper GI contents to the interior body cavity (Byrd et al., 2002). Poultry establishments can benefit from awareness of these factors that lead to contamination and can implement necessary machinery checks to ensure that evisceration equipment is indeed functioning effectively. Figure 6 Best practice: This manual venting gun is rinsed with chlorinated water, supplied to the gun by the red hose, between each carcass . Carcass rinses or sprays can be effective interventions for removing incidental contamination from the carcass surface during evisceration. However, establishments can aim to consistently implement sanitary dressing procedures to control pathogens. Rinses with an antimicrobial have been shown to reduce *Campylobacter* by 1.5 log", "33 (Bashor, et al., 2004). When applying water rinses and sprays, establishments can consider the water pressure applied. Some studies have found that elevated spray pressure may force bacteria into muscle or skin rather than washing it off (Buncic & Sofos, 2012). Note: This guideline uses the term \u201cfree available chlorine\u201d when referring to parts per

million (ppm) chlorine. Free available chlorine is the concentration of hypochlorous acid (HOCl) and hypochlorite ions (OCL) existing in chlorinated water. (Reference: Handbook of Chlorination and Alternative Disinfectants, Geo. Clifford White, Fourth Edition 1998. Wiley Interscience). Rinses or sprays can be designed, installed, and calibrated to remove incidental contamination. When not properly designed or implemented, rinses or sprays may not effectively remove contamination and may even spread contamination from one part of the carcasses to another part or even to adjacent carcasses. Figure 7 shows a rinse that is not calibrated to wash contamination. Figure 8 shows sprays that spread contamination onto other parts of the carcass. Figure 7 Not recommended: Rinses are not positioned to wash contamination off tail area. On the left, a contaminated carcass moves on the line toward two washes. On the right, the carcass has moved past the washes, and the contamination remains. In this situation, if the nozzles were moved up, it is likely that due to the high pressure and angle of the spray, contamination may not be washed off but instead may spread to surrounding areas of the carcass. Key Point Antimicrobial interventions are not a substitute for consistently implementing sanitary dressing practices.", "34 Figure 8 Not recommended: Overspray spreads contamination to adjacent areas of the carcass. In the closeup on the right, the middle spray bar results in splashing of water from the thigh up over the back of the thigh and onto the abdomen area (under yellow arrow), where it will run down the breast area. The contaminated vent area visible on the left (inside the red box) will not be washed off when it goes through the middle spray bar. Instead it will spread contamination to adjacent areas. This is also true of the faint yellow contamination on the outside of the thigh and bird's side (black bar of the right image). Multiple Campylobacter controls throughout the evisceration process are recommended. Pathogens are not effectively removed by using one carcass rinse, and a multiple hurdle approach works best against pathogens. Some poultry processors consistently produce Campylobacter positive carcasses, while others produce carcasses that upon testing typically do not have detectable levels of Campylobacter. These variable test results may be the result of differences in sanitary dressing practices. Sanitary dressing practices are implemented throughout the slaughter process, in a manner that produces a clean, safe, wholesome poultry product in a sanitary manner. For example, rates of visible contamination on the carcasses after crop removal vary greatly depending on crop removal practices. In some establishments, fewer crops rupture because the crops are extracted toward the head (and downward) rather than toward the thoracic inlet (and upward) (Buhr et al., 2000). This is an important consideration for Campylobacter control because crop tissue often contains Campylobacter (Byrd et al., 1998). Note that some carcasses may become incidentally contaminated with feces and ingesta even with strict sanitary dressing practices. However, fecal contamination can be minimized with strict sanitary dressing practices.", "35 Chilling This is the point where eviscerated carcasses are chilled in order to inhibit microbial growth and meet the regulatory requirements of 9 CFR 381.66(b)(3). Additional information on chilling requirements can be found in the FSIS Compliance Guide: Modernization of Poultry Slaughter Inspection: Chilling Requirements. Antimicrobial Intervention Use for On-line and Offline Reprocessing and for Chilling Procedures Reprocessing systems are used to control Campylobacter on visibly contaminated carcasses. Both on-line (OLR) and off-line (OFLR) reprocessing systems can be used to remove incidental contamination during the evisceration. On-line reprocessing is not a remedy or a substitute for poor sanitary dressing practices during evisceration. The on-line reprocessing

system may be able to remove visible contamination, but the invisible contamination can remain if the intervention is overwhelmed. NOTE: Carcasses must be free of visible fecal contamination prior to entering the chilling system as required by 9 CFR 381.65(f).

Recommended Best Practices \u2013 Evisceration 1. Adjust and maintain equipment regularly as needed to accommodate bird size. 2. Implement an antimicrobial rinse to reduce equipment contamination. 3. Implement multiple hurdles to reduce pathogens.", "36 FSIS has posted lists of the approved OLR and OFLR systems. The lists are regularly updated and attached to FSIS Directive 7120.1, Safe and Suitable Ingredients Used in the Production of Meat, Poultry, and Egg Products. If an establishment desires to use an OLR or OFLR system that has not been approved by FSIS\u2019s Risk Management and Innovations Staff (RMIS) or wishes to modify an approved OLR or OFLR system, the establishment is responsible for submitting a protocol to FSIS requesting permission to conduct an in-plant trial. Per the Memorandum of Understanding (MOU) between FDA and FSIS, FSIS would consult with FDA regarding safety of the proposed chemical. FSIS would review the protocol for any prohibitions that can potentially affect product safety, safety of inspection personnel, interfere with inspection procedures, or require a change to the Agency\u2019s regulations. If the in-plant trial is granted, FSIS would issue a letter granting permission to conduct an in-plant trial. More information regarding in-plant trials can be found in the FSIS Compliance Guideline Procedures for New Technology

Notifications and Protocols. An establishment that uses chlorine or other antimicrobials as a part of its sanitary dressing and process control procedures, or employs a pre-chill carcass wash that may affect the pH of the chiller water, can consider the effect of pH on the efficacy of any antimicrobials used in the chiller. On Line Reprocessing Addresses incidental fecal or ingesta contamination during evisceration Utilizes washing systems and antimicrobial systems to achieve desired results. Off line Reprocessing Addresses disease conditions and contamination that cannot be removed by other means Produces carcasses microbiologically equivalent to those routinely eviscerated on line", "37 Further Processing This section of the guideline provides information for establishments that further process raw poultry carcasses to produce products such as: \u2022 Poultry parts \u2022 Injected, mechanically tenderized, or vacuum tumbled poultry products \u2022 Commminuted (including ground) poultry products, includes products such as patties and sausages that are made using comminuted poultry \u2022 Stuffed chicken products Source Materials Can Affect Pathogen Status of Commminuted Product Certain poultry parts may be more likely to be contaminated with pathogens and therefore riskier to use as source materials to produce comminuted poultry products. The FSIS Chicken Parts Baseline study (FSIS, 2013) found that chicken necks were significantly more likely to be contaminated with Campylobacter (55%) than other parts, including breasts, legs, and wings (between 16-43% for Campylobacter). Establishments can consider not using chicken necks in comminuted poultry products or only using them in comminuted products that are intended for a lethality treatment. Similarly, skin-on and bone-in source materials used in comminuted chicken products present increased risk of contamination with Campylobacter. As previously discussed, skin can contain Campylobacter in feather follicles that can be exposed during the grinding or other comminuting process and spread throughout a lot. Chicken neck skin has typically been found to be more contaminated than other parts of the carcass. Table 3 shows that ground and other raw comminuted chicken products (such as sausages and patties) sampled by FSIS that were produced using skin-on source materials were more likely to be

contaminated with Campylobacter2. Table 4 shows the risk for use of bone-in source materials for comminuted turkey products. 2 FSIS Not Ready-to-Eat Comminuted Poultry Exploratory Sampling Project results from samples collected June 1, 2013 through June 30, 2015. Key Point Comminuted products are those that are ground, mechanically separated, or hand- or mechanically-deboned and further chopped, flaked, minced or otherwise processed to reduce particle size.", "38 Table 3. FSIS exploratory sampling testing results, raw comminuted chicken by source material composition (6\1\13-6\30\15, 2,688 samples) The interior of poultry bones can contain pathogens as well. Because of the nature of comminuted processes, contamination can spread throughout an entire batch or lot from a few contaminated bones through cross contamination. FSIS sampling data indicates that both chicken and turkey raw comminuted products produced using bonein source materials are more likely to be contaminated with Campylobacter than those produced using deboned source materials. Table 3 shows this for comminuted chicken products, and Table 4 shows this for comminuted turkey products. Tables 3 and 4 indicate pathogen prevalence for comminuted products based on whether source material contained bone (chicken and turkey) or skin (chicken only). Analysis of FSIS comminuted poultry sampling results shows that it is more likely that comminuted chicken will be positive for Campylobacter when its source materials contain both bone and skin (12.1%). Comminuted chicken made from deboned and skinless source materials had the lowest prevalence for Campylobacter (1.7% for Campylobacter). 3 For bone-in and skin-on source materials, Campylobacter prevalence in comminuted chicken was 12.1%. The lowest prevalence product, made from deboned and skinless source materials, was 1.7%. To calculate the relative risk, each source material type was divided by the lowest risk product: 12.1\1.7 = 7.1. Comminuted Chicken Products Campylobacter prevalence in this source material Campylobacter presence risk relative to the lowest prevalence source material (Deboned & skinless)3 Mechanically separated 20.2% 11.9-fold increase Ground and Other Comminuted Chicken Products Campylobacter prevalence in this source material Campylobacter presence risk relative to the lowest prevalence source material (Deboned & skinless)3 Bone-in & Skin-on 12.1% 7.1 Bone-in & Skinless 4.4% 2.6 Deboned & Skin-on 3.6% 2.1 Deboned & Skinless 1.7% N\A", "39 The tables also indicate how much more likely products made from different source materials are to contain Campylobacter, as compared to the product with lowest prevalence (products made from deboned and skinless source materials). Raw comminuted chicken products made from bone-in and skin-on source materials were more likely to be positive for Campylobacter compared to those made from deboned and skinless source materials.3 Mechanically separated poultry products nearly always contain skin and bones in their source materials, because of the nature of the processing of this product. FSIS sampling results indicate that Campylobacter prevalence was highest for mechanically separated chicken. For this reason, establishments can consider not using mechanically separated chicken as a component in not-ready-to-eat (NRTE) comminuted products, or only using it in comminuted products that are intended for a lethality treatment. Table 4. FSIS exploratory sampling testing results, raw comminuted turkey by source material composition (6\1\13-6\30\15, 934 samples) Comminuted Turkey Products Campylobacter prevalence in this source material Campylobacter presence risk relative to the lowest prevalence source material (Deboned) Mechanically separated 2.4% 1.2-fold increase Ground and Other Comminuted Products Campylobacter prevalence in this source material Campylobacter presence risk relative to the lowest

prevalence source material (Deboned) Bone-in 9.8% 4.9 Deboned 2.0% N/A It is important to keep in mind that the data in Tables 3 and 4 represents FSIS data from all establishments sampled in the exploratory program, without consideration of the amount of skin or bone going into comminuted processes. Each individual establishment can determine the extent that skin-on and bone-in source materials may contribute to pathogens in finished product. This determination can be made by sampling and testing comminuted products made from different source materials. Establishments that do not test products by source material can consider the information provided in the tables during decision-making in their processes. Using the information in the prevalence column of the tables, establishments can compare the relative risk of using different types of source materials. For example, in the absence of ", "40 its own sampling results, a chicken establishment can compare using bone-in and skinon source materials (12.1% Campylobacter prevalence) with using deboned and skinon source materials (3.6%) to determine that the relative risk is 3.36 (12.1\3.6). This means there is about a 3 times greater chance that the bone-in source material will result in Campylobacter being present in the finished product. Therefore, there is likely a benefit to using the deboned source materials instead of the bone-in source materials. Additional guidance regarding the use of in-house source materials and incoming source materials purchased from supplying establishments, including the use of Certificates of Analysis or Letters of Guarantee, is available in the FSIS Guideline for Controlling Salmonella in Raw Poultry. Interventions Unless otherwise stated, interventions (antimicrobial processing aids) described in this section have been reviewed for safety and suitability and are listed in FSIS Directive 7120.1. Establishments, intervention manufacturers, and other users that would like to implement interventions not listed in FSIS Directive 7120.1 would need to submit for review a protocol to FSIS describing the proposed function of the substance in the specific poultry or meat product and conditions of use, as described in the FSIS Compliance Guideline Procedures for New Technology Notifications and Protocols. Establishments may consider using interventions during further processing to decrease pathogens. Antimicrobial interventions may be applied to source materials prior to further processing, to parts, during grinding or other comminuting process, and during blending of ground or comminuted products. Establishments should consider all applicable labeling requirements when choosing an antimicrobial, in particular when adding aqueous solutions to products with a standard of identity that does not allow added water (e.g., \u201cground chicken\u201d; 9 CFR 319.15(a)). High pressure pasteurization (HPP) is another intervention that may be applied to raw comminuted product. Although applying interventions to source materials used in comminuted products can reduce pathogens in finished product, contamination may still occur during the process itself when skin or bones are broken, releasing bacteria that were not exposed to the antimicrobial application. Establishments can consider these factors when evaluating their use of interventions. Establishments can evaluate the adequacy of any Campylobacter interventions they apply to parts during further processing, including those source materials that are specifically intended for non-intact use (such as grinding or other comminuted processes). Part of the evaluation can include consideration of variability of Campylobacter levels on source materials. That consideration also applies to parts that are sent to other establishments for any kind of further processing because they may be used as source materials in comminuted or otherwise non-intact raw product. Interventions to control Campylobacter can be applied by spraying or dipping (immersion). Generally,

immersion is more effective than spraying because it ensures better coverage and longer contact time (Loretz, 2010). A potential challenge with<sup>41</sup> immersion is maintaining the proper level of active chemical as it becomes absorbed and neutralized by organic material, such as fat and protein. Another challenge with immersion is maintaining the active concentration of the intervention despite the natural decomposition of the compound as a result of chemical reactions, heat, or light. It is important to verify with sufficient frequency that the critical operational parameters of an antimicrobial dip are maintained. It may be necessary to either add more chemical or even to completely change the solution to maintain effectiveness. Figure 9 shows an antimicrobial dip being applied to boneless, skinless poultry parts prior to grinding. Figure 9 Best practice: Boneless, skinless poultry parts receive an antimicrobial dip prior to being ground. The following pages present information on some antimicrobial interventions that may be used during further processing and which have been studied to control pathogens during further processing. This information is summarized in the attachment to this guideline. Establishments need to adhere to the limits in the conditions of use for chemicals as described in FSIS Directive 7120.1 and 9 CFR 424.21. In addition, the establishment needs to determine the optimum concentration for its process based on the critical operational parameters in its scientific support documentation. Any ranges for pH, concentration, or other parameters included in this section are provided to give a general indication of these values, but they do not represent critical operational parameters.<sup>42</sup>

Inorganic and Organic Chlorine-based Treatments Chlorine is relatively inexpensive, has a broad spectrum of activity, and is quick acting. Its drawbacks include corrosiveness to processing equipment at low pH, loss of effectiveness at higher pH values, loss of effectiveness with increasing organic matter load, and longer contact time required as compared to some other antimicrobial interventions. Commonly used chlorine compounds include liquid chlorine, hypochlorites, inorganic chloramines, and organic chloramines. Chlorine is typically used at pH 6.0 – 7.5. A number of chlorine entries for use with poultry are in the FSIS Directive 7120.1 lookup table along with their acceptable uses. Chlorine added to water produces free available chlorine in the forms of hypochlorous acid and hypochlorite ions. Hypochlorous acid is the form most lethal to microorganisms. Acidified Sodium Chlorite Acidified sodium chlorite (ASC) is a type of chlorine compound that is a strong oxidizer. It enters bacterial cells and weakens or kills them by lowering the pH inside. ASC is safe and suitable for use on poultry carcasses and parts at concentrations of 500-1200 ppm, as indicated in FSIS Directive 7120.1. It is used at pH 2.3 - 2.7 and acidified with an organic acid, such as lactic acid, citric acid, or acetic acid. A benefit of ASC is that it is not as highly affected by the presence of organic material as chlorine. Oyarzabal et al. (2004) reported ~ 1 log reduction of *Campylobacter* and Mehyar et al. (2005) reported a 1.5 log reduction in *Campylobacter* on inoculated drumsticks. Trisodium Phosphate Trisodium phosphate (TSP) is an inorganic, non-chlorine-containing compound with a high pH. Its pH is between 11-13 and is used at concentrations of 8 – 12%. A benefit of high pH is that it gives TSP detergent-like activity, which can improve effectiveness against microorganisms. The main disadvantage of using TSP is disposal, as the high discharge of phosphate into the sewer may be a violation of local, state, or federal Environmental Protection Agency sewer discharge regulations. Recommended Best Practices, Interventions during Further Processing 1. Applying antimicrobial interventions during further processing can be part of an effective multiple hurdle approach to reducing pathogens. 2. Dipping is generally a better

application method than spraying as it ensures full coverage of an intervention for a longer period of time." "43 Quaternary Ammonium Compounds Quaternary ammonium compounds (QAC) are a group of positively charged organic compounds that may have detergent-like properties (Schmidt, 2012). Most have a high pH (pH 6-10), are used at concentrations  $\leq 1\%$ , and are effective in killing a wide variety of microbes. Cetylpyridinium chloride (CPC) is an example of a QAC. CPC is an odorless, colorless, stable compound that does not self-decompose and is not affected by organic material. QACs persist in solution for a relatively long time. QACs are not compatible with soaps, anionic detergents, or low pH solutions. CPC must be rinsed off poultry after use with water containing no more than 50 ppm chlorine. The major disadvantage of QAC is that some may be less effective in hard water that contains  $>500 \text{ mg/L}$  hardness (Miller, 2012). Organic Acids and Organic Oxidizers Organic acids and organic oxidizers used at the proper pH are effective in being able to enter bacteria to inhibit or kill them from the inside. Peroxyacetic acid (PAA) is an organic oxidizer. It has been studied on poultry parts to control pathogens. PAA is a mixture of the peroxy compound, hydrogen peroxide, and acetic acid. It is a versatile compound, as different formulations are available that may be used over a wide temperature range (0 to  $40^\circ\text{C}$ ) and a wide pH range (3 to 7.5). PAA is affected by protein or other organic materials to a lesser degree than chlorine is. When added to the chiller at a concentration of 200 ppm for one hour of contact time, PAA demonstrated a 1.5 log reduction of *Campylobacter* (Bauermeister et al., 2008). Applied as a dip with 1000 ppm PAA and a 20 second contact time demonstrated a 2.0 log reduction of *Campylobacter* (Nagel et al., 2013). In contrast, when applied as a spray, PAA requires increased contact time/increased concentrations to achieve similar reductions (Bertram et al., 2019). Studies Comparing Chemical Interventions In a study by Chen et al. (2014), researchers treated *Campylobacter* inoculated chicken parts (bone-in and skin-on) with chlorine, PAA, and CPC at various concentrations in a chilled immersion system for 25 sec. PAA and CPC significantly reduced *Campylobacter* in a dose-dependent manner. Water and chlorine had little effect in reducing *Campylobacter*. Another study by McKee et al. (2013) compared the pathogen reduction of antimicrobial interventions applied to chicken parts, including those used to produce ground product. Preliminary research shows that parts immersed/dipped into a tank containing antimicrobials had the greatest reductions. Findings from this study suggest that dips/immersions are more effective than single spray systems when treating parts because of their longer contact times and complete coverage." "44 Bacteriophages Bacteriophages (also called phages) are naturally occurring organisms (viruses) that infect only a specific host bacteria (Hagens & Loessner, 2010). Phages cannot infect humans (Lu & Breidt, 2015). Phages are ubiquitous in the environment in the water, in soil, and on food consumed (Guenther, 2009). Once phages infect bacteria, they can multiply inside of the bacteria, destroy the cell wall of the bacteria, and then be released into the environment where they can infect other susceptible bacteria. Phage preparations for *Campylobacter* have been developed, but have not yet been approved for use in FSIS-regulated products; inclusion in FSIS Directive 7120.1 for use in meat, poultry, egg, or fish products would require a New Technology submission for review of these phage applications. Physical Interventions Electrolyzed Oxidizing Water Treatment Electrolyzed oxidizing (EO) water is inexpensive, must be generated on-site with specialized equipment, has strong bacterial killing effect, and has little residual (longlasting) effect. EO water is acidic and is an effective antimicrobial immersion/dip solution. However, it usually requires much longer

contact time than other interventions, so spraying may not be an appropriate application method. EO water is produced by passing direct current voltage through a dilute sodium chloride (salt) solution. The result of the reaction is the production of two types of water (Hsu, 2005). It is the EO water that has low pH (2.3-2.7), high oxidation-reduction potential (>1000 mV), and high dissolved oxygen. A high oxidation-reduction potential means that more oxidation will occur. That translates to a greater capacity to form free radicals that kill bacteria (Venkitanarayanan, 1999). Huang (2008) and Hsu (2005) provide detailed descriptions on the concepts. The production of EO water containing sodium chloride (1-12% w/v) results in the formation of sodium hypochlorite (NaOCl) and hypochlorous acid (HOCl). HOCl functions as if chlorine gas was added into the poultry parts disinfection solution without the need to store a dangerous gas. It is important to point out that although EO water is strongly acidic, it is different from strong acids, such as hydrochloric acid or sulfuric acid, in that it is not corrosive to skin, to mucous membranes in the nose and lungs, or to poultry carcasses or parts (Huang, 2008). However, the HOCl (sodium hypochlorite) generated by the EO process may cause breathing irritation that can be reduced with proper ventilation (Huang, 2008). In a study by Park and others (2002), EO water treatment with a contact time of only 10 seconds demonstrated an equal reduction of *Campylobacter* as chlorinated water (50 ppm) at about 3 log<sub>10</sub> CFU/g.

"45 High Pressure Inactivation A typical high pressure pasteurization (HPP) system consists of a pressure vessel, pressure transmission fluid (usually water), and pressure generating pumps. HPP is a technology by which a product is treated at a very high pressure. HPP requires specialized equipment and is usually applied off-site where that equipment is located. HPP treatment kills or inhibits microorganisms, and researchers have studied its effectiveness in reducing pathogens in comminuted chicken and chicken parts. An advantage of using HPP is that surviving microorganisms can be more sensitive to other types of antimicrobial interventions as compared to bacteria that have not been exposed to HPP (Alpas, 2000). Liu (2012) investigated high pressure inactivation of *Campylobacter* in comminuted chicken breast meat (individual meat particle size of \u22641 mm<sup>3</sup>) inoculated with *Campylobacter jejuni* at 6 log CFU/g. Polyethylene glycol was used as the pressure transmission fluid. Compression and decompression rates were 300 MPa/min. The temperature of the system was maintained by a water-jacketed unit. The temperature during compression and decompression did not exceed 2\u00b0C. Pressure at 400 MPa for 30 min reduced *Campylobacter* counts from 6 log to below the detection limit of 1.48 log CFU/g (reduction of approximately 4.5 log). Cryogenic Freezing Cryogenic freezing is defined as freezing at -74.2\u00b0F (-59\u00b0C) or below (Balasubramanian, 2012) using liquefied gases called cryogens. Two popular cryogens used are liquid carbon dioxide (CO<sub>2</sub>) and liquid nitrogen (N<sub>2</sub>). Cryogens are completely inert (non-reactive or flammable), colorless, odorless, tasteless, and have minimal environmental effects. Tunnel and spiral belt are the two common commercial designs (Shaikh & Prabhu, 2007). Cryogenic freezers are insulated enclosures or chambers surrounding a product conveyor with a method to introduce and regulate the amount of cryogen into the chamber. It is important to note that during cryogenic freezing, meat is not immersed into the cryogen, e.g., liquid carbon dioxide or liquid nitrogen. The meat is sent on a conveyor a short distance above the cryogen. It is the vapor of the cryogen that causes the meat to freeze. Gunther (2015) studied the effect of cryogenic freezing (using liquid nitrogen vapor) on *Campylobacter*-inoculated ground turkey patties containing

polyphosphates. It is important to note that polyphosphates are not part of the cryogenic freezing process. Rather, some establishments add polyphosphates during routine poultry processing to enhance the moisture absorbance, color, and flavor and to reduce product shrinkage of poultry. Gunther analyzed the patties for surviving Campylobacter after the patties were cryogenically frozen at -80°F (-62.2°C) for 4 minutes (using liquid nitrogen vapor) and stored at -20°F for 7 and 33 days.<sup>46</sup> This treatment achieved log reductions of Campylobacter in the frozen patties after 7 and 33 days at -20°C of 2.5 logs and 3.2 logs, respectively. Cryogenic freezing is similar to individual quick freezing (IQF) in that the outcome results in poultry that is completely frozen solid. The way cryogenic freezing differs from IQF is the technology used to achieve the frozen state, including how it is applied to product and associated operational parameters. Establishments performing IQF typically use conventional compressor-type refrigeration units, e.g., blast freezing such as in spiral freezers. It would not be sufficient to indicate that IQF or other processing freezing procedures reduce pathogens without scientific support that such a procedure results in a pathogen reduction and identifies the associated critical operational parameters.

**Irradiation using Ionizing Radiation**

Food irradiation is the process of exposing food to high levels of radiant energy and is applied by directing ionizing radiation to food products. Food can be irradiated commercially for several purposes: to extend shelf-life, eliminate insect pests, or reduce numbers of pathogenic microorganisms. Ionizing radiation can penetrate deeply into food, killing insect pests and microorganisms without raising the temperature of the food significantly (Jaczynski, 2003). Ionizing radiation kills bacterial cells and pests by damaging DNA (Tahergorabi, 2012; Verma, 2001). Ionizing radiation results from cobalt-60, cesium-137, x-rays, and electron beams.

Cobalt-60 (<sup>60</sup>Co) is a common source of a form of ionizing radiation called gamma irradiation. It has high penetrating power (Ahn, 2013), which allows the treatment of poultry of variable sizes, shapes, and densities (including frozen and unfrozen). X-rays are also used to produce ionizing radiation. X-rays have high penetrating power but are typically not used for treatment of food because it is not an efficient process (Tahergorabi, 2012). Another way of producing ionizing radiation is by applying an electron beam (e-beam). In this approach, a stream of high-energy electrons is applied to products. Because the radiation penetrates only a few centimeters, it is useful to treat thin layers of food (Jaczynski, 2003; Ahn, 2013). The electron beam may be applied over moving food on a conveyor, unlike some other sources of ionizing radiation. Electron beam systems require regular maintenance, high electric power, and cooling as the equipment produces high heat (Ahn, 2013). The maximum dosage of ionizing radiation is 3 kGy absorbed by raw poultry (fresh and frozen). The maximum dosage limit allowed for poultry is based on the safety determination that was made by FDA (21 CFR 179.26(b)(6)). A requirement that FDA placed on the use of irradiation is that the packaging of irradiated poultry must be air permeable and does not exclude moisture and microorganisms from penetrating the package barrier. To promote processing flexibility and innovation that will lead to improvements in food safety, FSIS does not specify at which point irradiation may or may not be applied.<sup>47</sup> Under HACCP, an establishment must control the conditions under which product is held from initial processing through irradiation and packaging to ensure and preserve the intended antimicrobial effects of irradiation (64 FR 72150). FSIS requires the labeling of irradiated meat and poultry products, including the radura symbol. These labeling requirements are outlined in the final rule, Irradiation of Meat Food Products, 64 FR 72150. One study found that applying

electron beam irradiation to boneless, skinless chicken breasts containing naturally occurring bacteria resulted in an approximately 5-log reduction in *Salmonella* and *Campylobacter*. The doses applied were 1.0 and 1.8 kGy at ambient temperature and both doses resulted in comparable reduction of *Campylobacter* (Lewis, 2002). 4 Irradiation of Meat Food Products; Final rule. Parameters are provided to guide establishments in choosing antimicrobial interventions that are appropriate to their processes. Values indicated are not critical operational parameters. Establishments need to identify the critical operational parameters used in their establishment and provide scientific support for the values they select. Intervention Pros Cons Typical parameters Reference Chlorine-Based Treatments - Inexpensive - Broad spectrum - Quick acting - Corrosive and outgases at low pH - Ineffective at high pH - Neutralized by high organic load - Formation of hazardous trihalomethanes pH: 6.0 \u2013 6.5 concentration: 20 \u2013 50 ppm free chlorine temperature: 4\u00b0C Application: dip or spray Bashor et al., 2014 Organic Acids - Low toxicity compared to some other chemicals - Broad spectrum - Not affected by hard water - Relatively stable in the presence of organic matter - Can be expensive - Can be corrosive at high temperatures pH range: 2.5 \u2013 5.4 concentration: 1.5 \u2013 5% temperature: 4\u00b0C application: dip or spray Zhao, 2006 Acidified Sodium Chlorite (ASC) -Inexpensive - Can form hazardous halogenated organic compounds - Neutralized by organic matter pH range: 2.3 \u2013 2.9 concentration: 500 \u2013 1200 ppm temperature: 4\u00b0C Application: dip or spray Wang, 2014 AlonsoHernando, 2013 Peroxyacetic Acid - Broad pH range - Broad temperature range - Affected by organic matter to a lesser degree than chlorine - No rinse required - expensive pH: 3.0-7.5 concentration: 100- 1000 ppm temperature: 4\u00b0C Application: dip or spray McKee, 2014 Chen, 2014","62 Intervention Pros Cons Typical parameters Reference Trisodium Phosphate (TSP) - Inexpensive - High pH may affect poultry after prolonged contact pH: 11 \u2013 13 concentration: 8 \u2013 12% temperature: 20 \u2013 30\u00b0C Application: dip or spray Capita, 2002 Del Rio, 2007 Electrolyzed Oxidizing (EO) Water Treatment - Noncorrosive to equipment and personnel - Inexpensive to operate - Solution rapidly loses antimicrobial activity if electrolysis is stopped - neutralized by organic matter - may be expensive to set up system EO water has the following characteristics: pH: 2.1 \u2013 2.7 OxidationReduction Potential (ORP): >1000 mV free chlorine: 8 \u2013 >70 mg/L Application: dip Huang, 2008 Park, 2002 Crust Freezing - No chemicals on food; no rinse required - Expensive to install - Requires source of CO<sub>2</sub> or N<sub>2</sub> Operates at approximately - 30\u00b0C to -55\u00b0C Application: N/A Georgsson, 2006 Boysen and Rosenquist, 2009

Cryogenic Freezing - No chemicals on food; no rinse required - Odorless, colorless, tasteless - Expensive to install and operate - CO<sub>2</sub> or N<sub>2</sub> are dangerous to handle Operates at approximately -59°C Application: N/A Shaikh and Prabhu, 2007 High Pressure Processing (HPP) - No chemicals on food; no rinse required - Expensive to install - Typically done at a separate establishment - Can alter appearance and texture of product Operates at pressures >100 MPa Application: N/A Liu, 2012 Simonin, 2012 Irradiation - No chemicals on food; no rinse required - Expensive to install - Typically done at a separate establishment - labeling requirement 22643.0 kGy packaging must be air permeable (21 CFR 179.26(b)(6)) Thayer 1991 and 1992"]}, {"file\_name": "FSIS\_GD\_2021\_0008", "title": "FSIS Industry Guideline for Minimizing the Risk of Shiga Toxin-Producing Escherichia coli (STEC) in Beef (including Veal) Slaughter Operations", "num": "FSIS-GD-2021-0008", "id": "cbb23be9a4566f230ef8a7d510294002e59546e8b18a89306b07b1949e8972d0", "co\_rpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/media\_file/2021-08/FSIS-GD-2021-0008.pdf", "type": "pdf", "n\_pages": 64, "word\_count": 17373, "text\_by\_page": ["This guideline is to assist establishments that slaughter beef (including veal) to: \u2022 Implement effective sanitary dressing procedures designed to prevent carcass contamination; \u2022 Implement effective decontamination and antimicrobial interventions; \u2022 Properly assess microbial testing results, including results for indicators of process control, at any point during slaughter; and \u2022 Use the results from the implementation of these components of the food safety system to assess the effectiveness of the overall HACCP system. Industry Guideline for Minimizing the Risk of Shiga Toxin-Producing Escherichia coli (STEC) in Beef (including Veal) Slaughter Operations 2021 Guideline", "2 Preface What is the purpose of this Guideline? The purpose of this guideline is to provide beef (including veal) slaughter establishments information concerning best practices at slaughter that may be used to prevent, eliminate, or reduce levels of fecal and associated microbiological contamination in beef (including veal), specifically (1) Shiga toxin-producing Escherichia coli O157:H7 and non-O157(STEC), and (2) Salmonella. For the purpose of this guideline, wherever it references beef, it includes veal. This document is not meant to be a comprehensive Salmonella control guide, however many of the best practices included in this document may also reduce Salmonella contamination that occurs during the slaughter process. This guideline provides guidance to assist establishments in meeting FSIS regulations. The guidance represents best practice recommendations by FSIS based on the most current science available and practical considerations. It does not represent regulatory requirements that must be met. Establishments may choose to adopt different procedures from those outlined in this guideline to prevent contamination, but they would need to support why those procedures are effective. This guideline represents FSIS\u2019 current thinking on this topic and should be considered usable as of the issuance date. This guideline is focused on assisting small and very small establishments in support of the Small Business Administration\u2019s initiative to provide these establishments with assistance under the Small Business Regulatory Enforcement and Fairness Act (SBREFA). However, all FSIS regulated beef slaughter establishments may be able to apply the recommendations in this guideline. It is important that small and very small establishments have access to a full range of scientific and technical support and the assistance needed to establish safe and effective

Hazard Analysis and Critical Control Point (HACCP) systems. Although large establishments can benefit from the guidance that FSIS provides, focusing the guidance on the needs of small and very small establishments provides those establishments with information that may be otherwise unavailable to them. FSIS strives to provide small and very small establishments with as much technical knowledge as possible through, in part, publication of best practices in industry guidelines. Establishments can apply this knowledge and best practices to their operations as they see fit to establish a compliant HACCP system. Who is this guideline designed for? FSIS designed this guideline for beef (including veal) slaughter establishments. The best practices discussed in this guideline may also be useful to establishments that slaughter bison. Key Point This guideline provides information concerning best practices at slaughter that may be used to prevent, eliminate or reduce levels of STEC in beef (including veal). Salmonella is also covered where scientific information is available.", "3 Is this version of the guideline final? Yes. This version of the guideline is final. FSIS responded to public comments received on the previous version of this guideline. Comments were received from two industry groups and one individual. FSIS made the following changes in response to these comments. \u2022 FSIS clarified that the Agency\u2019s recommendations are not regulatory requirements; \u2022 FSIS removed information pertaining to lymph node harborage of Salmonella and will include it in Salmonella specific guidance materials; \u2022 FSIS removed best practice recommendations on the use of chlorophyll to detect contamination on carcasses and air inflation for bunging; \u2022 FSIS clarified the Agency\u2019s recommendations on cattle washing to reduce pathogen transfer and added more information on humane handling during cattle washing; \u2022 FSIS added more information on pre-harvest interventions; \u2022 FSIS clarified the Agency\u2019s recommendations about when feet, eardrums, and bruises should be removed; and \u2022 FSIS provided more information to support its recommendations on chilling and storage of carcasses and parts; \u2022 After additional internal review, FSIS emphasized that it considers the presence of certain STEC strains to be adulterants when they are present in raw non-intact beef products and raw intact beef source materials intended for use in such non-intact beef products or when the intended use is unclear. These adulterant STEC strains include E. coli O157:H7 as well as strains that have certain O groups (O26, O45, O103, O111, O121, and O145) and contain two specific virulence genes (stx and eae). This addition was created to clarify FSIS policy regarding STEC in relation to product recalls; and \u2022 After additional internal review, FSIS added a section on how \u201cdrying\u201d can be used as an intervention to reduce pathogens, including STEC. FSIS will update this guideline in response to changes in science and technology and based on public comments, as necessary. What if I still have questions after I read this guideline? FSIS recommends that users of this guideline search the publicly posted Questions & Answers (Q&As) in the askFSIS database or submit questions through askFSIS. Documenting these questions helps FSIS improve and refine present and future versions of this guideline and associated issuances. When submitting a question, use the Submit a Question tab, and enter the following information in the fields provided: Subject Field: Enter FSIS Industry Guideline for Minimizing the Risk of Shiga Toxin- Producing Escherichia coli (STEC) in Beef (including Veal) Slaughter Operations 2021; Question Field: Enter question with as much detail as possible; Product Field: Select General Inspection Policy from the drop-down menu; Category Field: Select Sampling from the drop-down menu; and Policy Arena: Select Domestic (U.S.) only from

the drop-down menu. When all fields are complete, press Continue.", "4 Industry Guideline for Minimizing the Risk of Shiga Toxin-Producing Escherichia coli (STEC) in Beef (including Veal) Slaughter Operations Table of Contents Preface

.....	2 Why did FSIS develop this guideline? .....	6 What regulatory requirements are addressed by this guideline? .....	8 How should establishments use this guideline document to incorporate these recommendations into a comprehensive, robust food safety system? .....	9 What are the food safety hazards of concern during beef slaughter and where do they originate?
.....	10 What is the importance of sanitary dressing and process control procedures? .....	12 What verification activities related to sanitary dressing should establishments develop? .	14 What are pre-harvest considerations and best practices?.....	17 What are mud scores and how can establishments use them to improve their food safety system?
.....	17 What are best practices during cattle transport, receiving, and holding? .....	17 What are the best practices during sticking? .....	19 What are best practices during hide removal?.....	19 What are best practices during bunging? .....
.....	22 What are best practices during weasand rodding? .....	23 What are best practices during head removal?.....	24 What are best practices during brisket opening? .....	25 What are best practices during evisceration?

"Industry Guideline for Minimizing the Risk of Shiga Toxin-Producing Escherichia coli (STEC) in Beef (including Veal) Slaughter Operations Why did FSIS develop this guideline? Since issuing the first version of this guideline in September 2002, FSIS has made significant changes to policies and testing procedures affecting beef slaughter establishments. This guideline has been updated to reflect policy and procedural changes. Some of the more significant changes include: In October 2002, FSIS issued a Federal Register notice (FRN) 67 FR 62325 that required all establishments producing raw beef products to reassess their HACCP plans in light of new FSIS testing methods and higher prevalence estimates for E.coli O157:H7. In the September 20, 2011 Federal Register (76 FR 58157), FSIS declared six non-O157 STECs (O26, O45, O103, O111, O121, and O145) adulterants in raw, non-intact beef products and product components. In November 2011, FSIS issued FSIS Directive 6410.1, Verifying Sanitary Dressing and Process Control Procedures by Off-line Inspection Personnel (IPP) in Slaughter Operations of Cattle of Any Age to IPP to verify that cattle slaughter operations are implementing sanitary dressing and process control procedures and that the procedures they are implementing prevent contamination of carcasses and ensure that insanitary conditions are not created. Those instructions are still in place. In June 2012, FSIS began testing for non-O157 STEC in addition to E. coli O157:H7 in beef manufacturing trimmings (BMT). In June 2014, FSIS began analyzing for Salmonella in all raw beef samples it collects for STEC analysis. FSIS announced its intention to develop a new ground beef performance standard for Salmonella based on these data. In August 2014, FSIS began a Beef-Veal carcass baseline study to test carcasses for the presence\absence and levels (enumeration) of STEC, Salmonella and certain indicator organisms during the beef slaughter process. FSIS intends to use the results from this study to develop guidance for establishments that slaughter beef-veal to use in assessing their process control of sanitary dressing and other slaughter controls. In August 2014, FSIS issued the revised FSIS Compliance Guideline for Establishments Sampling Beef Trimmings for Shiga Toxin-Producing Escherichia coli (STEC) Organisms or Virulence Markers concerning the sampling of BMT for STEC. The guidance includes information on the development and implementation of statistical process control procedures that slaughter\fabrication establishments can use to assess (1) the effectiveness of their controls for preventing contamination to the carcass during the slaughter process and (2) to verify they

are reducing STEC to a non-detectable level. The guidance also recommends criteria for high event periods (HEPs). In January 2015, FSIS issued FSIS Directive 10,010.3 Traceback Methodology for Escherichia Coli (E.coli) O157:H7 in Raw Ground Beef Products and Bench Trim to IPP on how to conduct traceback activities from the grinder or bench trim establishment and to verify that an establishment's action in response to an HEP is appropriate. In September 2015, FSIS issued Sanitary Dressing and Antimicrobial Intervention",<sup>7</sup> Implementation at Veal Slaughter Establishments: Identified Issues and Best Practices. This document identifies best practices for sanitary dressing specific to Veal slaughter establishments. Cattle have been identified as an important reservoir for pathogens, including STEC and Salmonella, which are known causes of foodborne disease. The hides, hooves, and gastrointestinal (GI) tracts of cattle can contain these pathogens. Contamination can be transferred from the hide, hooves, and GI tracts of cattle through poor sanitary dressing procedures. Effective sanitary dressing procedures underpin the interventions that an establishment has in place to prevent, eliminate, or reduce to an acceptable level, the food safety hazards that are reasonably likely to occur in the slaughter process. FSIS recommends that slaughter operations focus on their sanitary dressing procedures to prevent carcass contamination and the creation of insanitary conditions. Poor sanitary dressing procedures result in carcass contamination (visible or invisible, e.g., fecal or nonvisible microbial contamination) and limit the effectiveness of antimicrobial interventions. FSIS developed this guideline to assist establishments that slaughter beef (including veal) to prevent and minimize the risk of STEC in their operations. This guidance will: Help establishments design comprehensive written sanitary dressing programs that focus on preventing contamination of the carcass throughout the slaughter process; Describe for establishments how to implement antimicrobial interventions effectively; and Assist establishments with developing verification activities to ensure sanitary dressing procedures are consistently performed and effective. As described in the FSIS Compliance Guideline for Establishments Sampling Beef Trimmings for Shiga Toxin-Producing Escherichia coli (STEC) Organisms or Virulence Markers, establishment verification testing results for BMT are likely the best available objective information a slaughter establishment can use to determine the ongoing effectiveness of its slaughter/dressing operation. Establishments that incorporate statistical process control procedures into their testing programs, as described in the beef trimmings sampling guideline, and apply the information and best practices in this guideline should have an improvement to the design and implementation of their slaughter HACCP system. Further, in the beef trimmings sampling guideline above, FSIS recommends that Key Points Most food safety hazards inherent in raw processes originate with the live animals that enter the slaughter establishment. Salmonella and STEC are commonly found in the GI tract, and on the hides, and hooves of cattle. Effective sanitary dressing procedures during slaughter can reduce microbial contamination.",<sup>8</sup> slaughter establishments develop criteria for identifying HEPs or to follow FSIS criteria for identifying HEPs. HEPs are periods of time in which slaughter establishments experience a high rate of positive results for STEC (or virulence markers) in BMT samples from production lots containing the same source materials. That is, the BMT was produced from one or more carcasses slaughtered and dressed consecutively or intermittently within a defined period of time (e.g., shift). A HEP may mean that a systemic breakdown of the slaughter/dressing operation has occurred and has created an insanitary

condition applicable to all parts of the beef carcass (e.g., primal cuts in addition to the BMT and other raw ground beef and patty components). FSIS recommends that establishments identify HEP criteria so that they can determine whether they need to withhold product from commerce when a HEP has occurred. A HEP may indicate more widespread adulteration of product, beyond the specific product found positive. If establishments identify and respond to a HEP, they will minimize the chance that they release adulterated product into commerce. More information on the development and implementation of statistical process control procedures, recommended criteria for identifying a HEP, and guidance for responding to a HEP are included in the FSIS Compliance Guideline for Establishments Sampling Beef Trimmings for Shiga Toxin-Producing Escherichia coli (STEC) Organisms or Virulence Markers. What regulatory requirements are addressed by this guideline? Regulation Description 9 CFR 310.18(a) Requires establishments to handle carcasses, organs, and other parts in a manner to prevent contamination. 9 CFR 416.1 through 416.5 Requires establishments to operate in a manner to prevent the creation of insanitary conditions and prevent product adulteration. 9 CFR 417.2(a)(1) Requires an establishment to conduct a hazard analysis to identify food safety hazards that might occur in the production process, assess which hazards are reasonably likely to occur, and develop measures to prevent, eliminate, or reduce the identified hazards to an acceptable level. 9 CFR 417.2(c)(3) Requires the establishment to develop critical limits for critical control points (CCPs) to control hazards that are reasonably likely to occur. 9 CFR 417.4(a)(2) Requires establishments to verify that the HACCP system is effectively implemented on an ongoing basis.", "9 How should establishments use this guideline document to incorporate these recommendations into a comprehensive, robust food safety system? This guideline provides an overview of the slaughter process and includes the best practices at each step in the slaughter process to minimize contamination. As discussed above, FSIS recommends that establishments develop written sanitary dressing procedures designed to prevent contamination from occurring throughout the slaughter process and to develop verification activities to ensure the sanitary dressing procedures are performed consistently and are effective. Establishments can use the information in Appendix 1, Establishment SelfAssessment Checklist, to develop written sanitary dressing procedures designed to prevent contamination throughout the slaughter process and design verification activities to ensure that their employees are performing the procedures on an on-going basis. Establishments can use Appendix 2, Carcass Sanitary Dressing Audit, to verify, in real-time using carcass audits, that their sanitary dressing procedures are effectively preventing contamination throughout the slaughter process. FSIS also recommends that establishments implement antimicrobial intervention treatments, as needed, to reduce contamination to acceptable levels. This guideline discusses antimicrobial intervention treatments, their role in a comprehensive food safety system, and how to design and implement their use effectively. FSIS recommends that establishments test BMT for STEC (or virulence markers) to assess the effectiveness of their controls for preventing contamination during the slaughter operation. As is discussed above, FSIS developed a guidance document, FSIS Compliance Guideline for Establishments Sampling Beef Trimmings for Shiga Toxin-Producing Escherichia coli (STEC) Organisms or Virulence Markers, for beef slaughter\fabrication establishments to use to develop and implement statistical process control procedures for STEC (or virulence markers) BMT testing to assess the effectiveness of slaughter operations. The beef trimmings sampling guideline also includes

recommended HEP criteria for identifying situations that indicate when a 9 CFR 417.5(a)(1) Requires establishments to maintain supporting documentation associated with the hazard analysis. 9 CFR 417.5(a)(2) Requires establishments to maintain decision-making documents associated with the selection and development of CCPs and critical limits, and documents supporting both the monitoring and verification procedures selected and the frequency of those procedures. Key Point \u2022 The goal of this guideline is to help establishments design and implement a robust food safety system to minimize product contamination, specifically with pathogens. \u2022 Establishments that use this guidance can reduce their likelihood of producing adulterated products." "10 systemic breakdown of the slaughter operation has occurred and created an insanitary condition applicable to all parts of the beef carcass (e.g., primal cuts in addition to the BMT and other raw ground beef and patty components). FSIS recommends that establishments use the beef trimmings sampling guideline with the information in this guideline to design and implement a robust food safety system to improve their process over time.

**Overview of the Beef Slaughter Process**

What are the food safety hazards of concern during beef slaughter and where do they originate? FSIS considers the presence of certain STEC strain adulterants when they are present in raw non-intact beef products and raw intact beef source materials intended for use in such non-intact beef products. These adulterant STEC strains include *E. coli* O157:H7 as well as strains that have certain O groups (O26, O45, O103, O111, O121, and O145) and contain two specific virulence genes (*stx* and *eae*). The best practices for effective sanitary dressing procedures, antimicrobial intervention strategies, and appropriate use of microbial data in decision-making as outlined in this guideline will assist establishments in reducing these pathogens. Most of the food safety hazards inherent in raw processes originate with the live animals that enter the slaughter establishment. Common hazards include the biological hazards of bacterial pathogens, the chemical hazards of residues and the physical hazards of foreign material. These hazards could be present in raw product in any step of food production. Enteric organisms, such as *E. coli* and *Salmonella* are commonly found as part of the normal bacteria of the intestinal tract of animals. Some strains, notably the STEC, including *E. coli* O157:H7, and certain *Salmonella* serotypes can cause serious foodborne illness in humans. Cattle may carry STEC and *Salmonella* in their GI tracts and these pathogens may also be present on the hides and hooves of animals presented for slaughter.

**KEY DEFINITIONS:**

- Sanitary Dressing:** The practice of handling carcasses by establishment employees and machinery in a sanitary environment and a manner that produces a safe and wholesome product.
- Process Control Procedure:** A defined procedure or set of procedures designed by an establishment to provide control of those operating conditions necessary for the production of safe, wholesome food. The procedures typically include some means of evaluating system performance by using process control criteria, actions to take to ensure the system remains under control, and planned measures to take in response to a loss of process control. The procedures can be used as support for decisions made in the hazard analysis."
- "11 What are the guiding principles for minimizing the risk of STEC at slaughter? The four main guiding principles for minimizing the risk of STEC contamination during the slaughter process are: 1) Effective sanitary dressing procedures; 2) Antimicrobial interventions; 3) Establishment validation and verification that the system is functioning as intended; and 4) Evaluation of slaughter procedures during all steps of the process. These principles are interrelated and are vital components of an effective slaughter food safety

system. A description of each principle follows.

**PREVENTION VALIDATED ANTIMICROBIAL INTERVENTIONS**

Slaughter operations should develop and validate sanitary dressing procedures that prevent carcass contamination and the creation of insanitary conditions throughout the slaughter process. Effective and consistently performed sanitary dressing procedures that focus on preventing contamination directly impact whether interventions used will effectively reduce pathogens. Establishments should implement decontamination and validated antimicrobial intervention treatments as needed to reduce STEC to a non-detectable level. Establishments are required to identify and maintain documentation that provides support for their interventions, and identify the critical operational parameters that are necessary for the interventions to be effective (element one of validation), and to", "12 As discussed in the FSIS Compliance Guideline HACCP Systems Validation best practice documents such as; this FSIS Guideline, the BIFSCO Best Practices for Beef Slaughter and FSIS Directive 6410.1, Verifying Sanitary Dressing and Process Control Procedures by Off-line Inspection Program Personnel (IPP) in Slaughter Operations of Cattle of Any Age, may be used as scientific support that an establishment\u2019s sanitary dressing program prevents contamination with microbiological hazards such as STEC. Best Practices for Sanitary Dressing and Process Control

**NOTE:** While the recommendations in this guide apply to both veal and cattle slaughtering establishments, specific recommendations for veal can be found in the September 2015 FSIS document Sanitary Dressing and Antimicrobial Intervention Implementation at Veal Slaughter Establishments: Identified Issues and Best Practices.

What is the importance of sanitary dressing and process control procedures? FSIS sampling has found enteric pathogens, including *Salmonella*, adulterant non-O157 STEC and *E. coli* O157:H7, in BMT. Additionally, FSIS has found these bacteria in other raw ground beef components (including head meat and cheek meat) and raw ground beef. The presence of these enteric pathogens in these beef products can be attributed, in part, to ineffective sanitary dressing and process control procedures that create insanitary conditions during slaughter.

**VERIFICATION EVALUATION** have in-plant observations, measurements, microbiological test results, or other information demonstrating the control measures in the HACCP system can perform as expected within a particular establishment to achieve the intended food safety objective (element two of validation). Establishments are required to develop and implement verification activities that demonstrate that their slaughter process is effectively reducing hazards. Verification activities should generate real-time data of employees performing procedures as written that verify the procedures were effectively implemented (e.g., carcass audits after points in the slaughter process where carcasses are vulnerable to contamination). Establishments should develop microbiological testing procedures designed to detect contamination in product lots and generate microbiological test results to demonstrate the lots are free of contamination. Establishments should be able to demonstrate process control of the slaughter process through review of data collected (i.e., the implementation of their sanitary dressing procedures, antimicrobial interventions, and verification testing results) to determine the overall effectiveness of their food safety system.", "13 Insanitary practices and conditions during slaughter can introduce microbial and visible contamination (e.g., fecal material, ingesta and milk) to carcasses and parts. Effective sanitary dressing and process control procedures, coupled with effective decontamination and antimicrobial intervention treatments, are necessary to prevent the creation of insanitary conditions. Establishments create the potential for the contamination of carcasses and parts

when they fail to control these procedures and treatments in their food safety systems. Effective sanitary dressing and process control procedures support the CCPs that an establishment has in place to prevent, eliminate or reduce to an acceptable level the food safety hazards identified in the slaughter process and support that the HACCP system is functioning as intended. If sanitary dressing and process control procedures are not properly implemented, the HACCP system may be inadequate. Insanitary practices can introduce a level of contamination that overwhelms the decontamination and antimicrobial intervention treatments used to reduce pathogens to acceptable levels. FSIS recommends that slaughter establishments should consistently focus on sanitary dressing and process control procedures to prevent carcass contamination and the creation of insanitary conditions in their operations. Fundamental sanitary dressing practices to prevent carcass contamination and the creation of insanitary conditions.

1. Maintain adequate separation of carcasses, parts and viscera during dressing to prevent cross contamination.

2. Routinely clean and sanitize or sterilize equipment and hand tools that are used to remove contamination or to make cuts into the carcass.

Cleaning and sanitizing equipment between each dirty cut and between each carcass are the most effective way to prevent insanitary conditions.

3. Design and arrange equipment to prevent the contact of successive carcasses and parts with contaminated equipment and do not allow the hide during its removal to flap or splatter which could cause contamination of the same or nearby carcasses.

4. Frequently wash hands, gloves, and aprons that come in contact with the carcass and parts.

Key Points

\u2022 Effective sanitary dressing measures address multiple points in the slaughter process where carcasses are vulnerable to contamination.

\u2022 All controls in slaughter and dressing procedures should be aimed at preventing contamination.

\u2022 If sanitary dressing and process control procedures are not properly implemented, the HACCP system may be inadequate."

"14 What verification activities related to sanitary dressing should establishments develop? Establishments should observe employees to verify that they are performing the sanitary dressing procedures as written. Establishments should verify that the procedures are effective by conducting carcass audits (periodic visual evaluation of the carcass throughout the dressing process, as shown in Appendix 2) and by sampling and testing BMT, other raw ground beef components (including head meat and cheek meat), and raw ground beef for microorganisms. Sampling for adulterant STEC (or virulence markers) in the products previously discussed is an important verification activity that demonstrates whether the establishment\u2019s HACCP system is effectively reducing STEC to below detectable levels and that hazard analysis decisions concerning STEC are supported on an ongoing basis. As explained in the FSIS Compliance Guideline for Establishments Sampling Beef Trimmings for Shiga Toxin-producing Escherichia coli (STEC) Organisms or Virulence Markers, establishment verification testing results for BMT are likely the best available objective information a slaughter establishment can use to determine the ongoing effectiveness of its slaughter\dressing operation. FSIS recommends that establishments incorporate their sampling and testing of beef products, in addition to their generic E.coli testing (9 CFR 310.25), into their process control procedures for sanitary dressing because the results from such testing are a direct reflection of the effectiveness of the slaughter operation. The establishment\u2019s process control criteria should define when its process is in control (such as an occasional, sporadic positive result) and when the establishment has lost process control as indicated by many positives over time. If past sample results lead establishment

management to believe the process is out of control, the establishment should carefully investigate to find all contributing causes. This type of investigation would be more involved than a follow-up investigation when an occasional positive result is found. Establishments should continually strive to eliminate STEC by tightening their process control criteria as they gain more control over their slaughter operations. FSIS has found that microbiological testing results can drive establishments to enhance their food safety systems when they use the test results to inform their processes and adjust their processes as needed in response to the test results. While performing the Beef Sanitary Dressing task, FSIS IPP verify whether cattle slaughter operations are implementing sanitary dressing and process control procedures and that the procedures they are implementing prevent contamination of carcasses and ensure that insanitary conditions are not created. (See FSIS Directive 6410.1, Verifying Sanitary Dressing and Process Control Procedures by Off-line Inspection Personnel (IPP) in Slaughter Operations of Cattle of Any Age). FSIS IPP also verify, through microbial sampling, HACCP verification tasks and Hazard Analysis 5. Implement decontamination and antimicrobial intervention treatments such as washes or sprays on carcasses and parts, in accordance with the limits selected by the establishment and documented to be adequate to address contamination.", "15 Verification (HAV) tasks for whether beef slaughter establishments adequately address STEC. (See FSIS Directive 10,010.1, Sampling Verification Activities for Shiga Toxin-Producing Escherichia coli (STEC) in Raw Beef products, and FSIS Directive 10,010.2, Verification Activities for Shiga Toxin-Producing Escherichia coli (STEC) in Raw Beef Products.) Enforcement, Investigations, and Analysis Officers (EIAOs) assess and analyze an establishment\u2019s food safety system to verify that the establishment is able to produce safe and wholesome meat products. (See FSIS Directive 5100.4 Enforcement, Investigations and Analysis Officer (EIAO) Public Health Risk Evaluation (PHRE) Methodology and FSIS Directive 5100.1, Enforcement, Investigations and Analysis Officer (EIAO) Food Safety Assessment Methodology.)", "16 Best Practices for Each Beef Slaughter Processing Step Pre-harvest Control Sticking Cattle Receiving & Holding Head Removal Rodding the Weasand Brisket Opening Packaging\Finishing Product Storage & Transport Carcass Fabrication Carcass Splitting Head & Cheek Meat Processing Chilling Bunging Hide Removal (manual & mechanical) Evisceration \uf073 Processing steps in red are points in the slaughter process where FSIS has identified deficiencies that contributed to multiple STEC positive results. See section on FSA findings for additional information on commonly identified deficiencies and best practices section for ways to mitigate risk.", "17 What are pre-harvest considerations and best practices? FSIS encourages pre-harvest interventions as the first control steps in an integrated beef products food safety system, and the Agency has developed a guidance document, Pre -Harvest Management Controls and Intervention Options for Reducing Shiga Toxin-Producing Escherichia coli Shedding in Cattle: An Overview of Current Research, explaining pre-harvest management controls for reducing STEC shedding in cattle. Pre-harvest interventions, adequate sanitary dressing procedures at slaughter, and adequate sanitary conditions during further processing are all part of an integrated approach to reduce the public health impact of STEC. Below are additional recommendations not covered in this pre-harvest guidance document. What are mud scores and how can establishments use them to improve their food safety system? Mud scores are classifications concerning the overall cleanliness of cattle lots at receiving. For example, establishments can classify cattle into four groups: 1) Cattle that are less than 25% covered by dirt or mud; 2) Cattle that are greater than

25% and less than 50% covered by dirt or mud; 3) Cattle that are greater than 50% and less than 75% covered by dirt or mud; and 4) Cattle that are greater than 75% covered by mud. After classifying cattle at receiving into one of these four groups, establishments can develop specific measures they will take based on the classification of the cattle for the lot or lots. For example, if the cattle are in the third and fourth classification groups, the establishment may decide to slow the line speed to give its employees more time to effectively dress the cattle that have higher gross contamination. The establishment may also add more trimmers or interventions, such as a hide-on carcass wash. It is important for the establishment to use the information it gathers at cattle receiving and develop measures to react to the information that is collected. Other factors should be considered when using mud scores to modify production processes. For instance, during certain times of the year, cattle may have higher mud scores than at other times of the year (e.g., winter months versus summer months) when seasonal animal handling practices may influence the mud score. Therefore, different scoring criteria and trend analysis that varies by season may be needed to identify outliers. What are best practices during cattle transport, receiving, and holding? This is the point where cattle arrive at the slaughter establishment and are held before slaughter. There is an increased potential for contamination with enteric pathogens such as adulterant STEC and Salmonella during this time because of the presence of these microorganisms on the hide and hooves, and in the feces of cattle. Additionally, transportation to the slaughter facility, handling during transport and unloading, and interaction with other cattle may cause stress and increased shedding of pathogens." , "18 Best Practices during Cattle Transport, Receiving and Holding \u2022 Identify and obtain cattle from farms or feedlots that employ one or more production system or feedlot controls shown to reduce the carriage of STEC and Salmonella. Effective farm and feedlot management and control can reduce fecal shedding of the organism, as well as reduce the microbial load on the animals, and in the intestinal tract. More information can be found in PreHarvest Management Controls and Intervention Options for Reducing Shiga Toxin-Producing Escherichia coli Shedding in Cattle: An Overview of Current Research. \u2022 Clean the unloading areas and pens periodically to reduce the contamination of animals. \u2022 Washing cattle may be considered to reduce visible contamination which in turn may reduce pathogen transfer to the carcass. If an establishment decides to wash livestock pre-slaughter, they should ensure the washing is done in a humane manner. \u2022 Apply a water mist in the holding pens to reduce dust and dirt particles. \u2022 Use a mud scoring system (a system to quantify the amount of mud on live animals) to identify cattle that may present an increased likelihood of contamination during hide removal. \u2022 Apply an approved bacteriophage treatment to incoming cattle and allow the bacteriophage appropriate contact time (a list of approved bacteriophages can be found in FSIS Directive 7120.1). \u2022 Determine the incoming bacterial load on animals through microbiological sampling and testing of incoming cattle hides. \u2022 Determine whether the age, type of cattle received (e.g. veal calves), or season (i.e., high prevalence season) represent a concern relative to pathogen load and whether adjustments to the food safety system need to be made as a result." , "19 What are the best practices during sticking? This is the point in the process where the animal is bled. Regardless of the slaughter method, it is important for the establishment to minimize contamination of the carcass during any cut conducted at this step. What are best practices during hide removal? This is the point in the process where the hide is removed from the animal. Hides are a

significant source of contamination, and hide removal represents the greatest opportunity for carcass contamination. Contamination may be visible (e.g., dust, dirt, feces, mud) or invisible (i.e., microbiological). Establishments should take appropriate measures to prevent contamination during the de-hiding process. The fact that hides are a significant source of contamination, and that hide removal represents the greatest opportunity for carcass contamination, is clearly illustrated in the study described in Nou et. al. 2004. This study sampled two groups of cattle at lairage and after de-hiding. One group of cattle underwent a typical de-hiding procedure. Sampling of these carcasses immediately after de-hiding showed that 50% were positive for E. coli O157:H7. The other group of cattle was subjected to a chemical dehauling process prior to hide removal. Carcasses in this group showed only a 1% positive rate for E. coli O157:H7 and a significantly lower level of other indicator organisms as compared to the other group of cattle. This study demonstrates that transfer of contamination from the hide is a major contributor to the microbiological load onto carcasses. Best Practices during Sticking \u2022 Keep the \u201cdry landing\u201d area where the stunned animals exit from the knocking box clean and dry of all blood, feces, ingesta, and mud between each animal. \u2022 Use one knife to cut through the hide, and another knife (or the same knife sanitized) to cut the artery. \u2022 Use a dual knife system (i.e., one knife is being used while one knife is being sanitized) and clean the hand between sticking each carcass. \u2022 Use the smallest cut possible to accomplish bleeding. \u2022 Ensure blood collection devices and blood containers for edible blood are clean. Rinse and clean the collection funnel and knife after each carcass and sanitize after each identifiable lot of blood is drawn. Do not save blood from condemned animals." "20 Best Practices during Hide Removal \u2022 Apply a validated hide-on intervention prior to hide removal. If cattle hides are wet after the antimicrobial treatment, remove excess moisture because run-off can contaminate exposed tissue during hide opening. Sanitized squeegees can be used to remove excess moisture from the hides to reduce the chance of contamination. \u2022 Mud balls on hides can also be a source of contamination. Establishments can use whizzard knives with dull blades or curry combs to remove the mud balls and other dirt from the hide prior to hide opening. \u2022 When using a bed or cradle for hide removal, remove the front and hind feet before making any other incisions through the hide. Minimize the amount of foreshank tissue exposed. \u2022 Ensure the skinning bed (for bed operations) is clean before lowering the carcass. \u2022 Prevent the neck and shoulders from contacting the floor when lowering the carcass into the skinning bed. If this is not possible, install a surface on the floor that can be sanitized where the neck and shoulders contact. \u2022 Prevent fecal matter that is expressed as the carcass is laid on the bed from contacting the exposed carcass. \u2022 Direct the knife toward the hair side of the skin when opening the hide to prevent contaminating the carcass. \u2022 Remove visible contamination at the cut line. \u2022 Steam vacuum or apply another validated antimicrobial treatment to pattern lines (cut lines where the hide is opened) even if visible contamination is not present. \u2022 Remove visible fecal contamination as soon as possible after it occurs to prevent microbial attachment. \u2022 Use a dual knife system or, if not possible, dip the knife in the sterilizer after each incision through the hide. \u2022 Space carcasses a sufficient distance apart to prevent contamination of skinned parts with adjacent carcasses. \u2022 Design facilities to provide sufficient spacing between carcasses and walls, platforms and other fixed objects." "21 Best Practices during Hide Removal (Continued) \u2022 Remove lactating udders

in a manner to prevent carcass contamination with udder contact. \u2022 Trim any contamination from udder content immediately. \u2022 Reflect the hide away and preferably downward from the carcass as skinning proceeds. Skin each area back far enough to permit the hide to stay in a rolled-back position before the Skinner proceeds to another skinning location. \u2022 Prevent hides from flapping and contacting exposed carcass. Using hide clips is one way to prevent hide flaps from contact with the exposed carcass. Clean and sanitize hide clips as necessary to prevent the creation of insanitary conditions. \u2022 Prevent contamination to the tail or carcass while skinning the tail. Frequently clean hands and equipment at this step because the tail and switch are highly contaminated with urine and manure. This is particularly important when the same employee performs other tasks involving carcass contact. \u2022 Clean and sterilize the clamp used to suspend the tail from the overhead spreader between each use or remove and discard the tip of the tail ahead of the clamped portion. \u2022 Remove tail switches and bag the tails before using the tail puller. \u2022 Inject air under the skin of skulls to facilitate hide removal from the head while using the hide puller. \u2022 Ensure that mechanical hide pullers, side pullers, and tail pullers are properly adjusted. If they are not appropriately adjusted (e.g., pulling too fast, hard, or contacting exposed carcass), they can lead to carcass contamination and splatter. \u2022 Monitor pullers on an on-going basis for proper adjustment. \u2022 When using mechanical hide pullers, the tremendous energy exerted during the final removal of the hide can generate aerosols. During this process best practices in preventing cross contamination are to:

- o Establish a maintenance program for the mechanical pullers;
- o Monitor pullers on an on-going basis for proper adjustment;
- o Install shields or devote an employee to hold up a shield; and
- o Direct air flow away from the carcasses being skinned to prevent contamination of carcasses with the aerosols created at this step.

"22 What are best practices during bunging? This is the point in the slaughter process where a cut is made around the rectum (i.e., terminal portion of the large intestine) to free it from the carcass, and then it is tied off and bagged to prevent spillage of fecal material. If the bung is not tied and bagged properly, the bung can contaminate the carcass. When bunging is performed before the hide of the rump is removed, the outside of the bag can become contaminated from the hide. Then, when the GI is removed during evisceration and the bagged bung is pulled through the pelvic inlet, the contamination on the outside of the bag can cause carcass contamination and the creation of insanitary conditions.

**Best Practices during Hide Removal (Continued)**

\u2022 A simple way to evaluate if the hide, side or tail puller is causing contamination is for an establishment employee to hold up a white piece of cardboard between the hide puller and the carcass during de-hiding and adjacent carcasses (to the side of and behind, if the line wraps around). If the piece of cardboard becomes dirty, the unit is likely causing cross-contamination and needs to be adjusted (i.e., the wheel spin needs to be slowed down) or the establishment should use shields.

\u2022 Apply a physical barrier (e.g., paper towels or plastic) to the carcass tissue adjacent to the hide to protect exposed carcass surface in the event the hide turns over when using the hide puller. In this case, if the hide turns over, the hide will touch the barrier rather than the exposed carcass tissue.

\u2022 Maintain clean mechanical hide puller contact points with the hide, hands, and garments of the employees handling the hide and the carcass, and knives and other equipment contacting the de-hided carcass.

\u2022 Apply antimicrobial treatments (e.g., organic acids) immediately after using the mechanical pullers.

\u2022 Place a hide chute where hides are removed from carcasses. Do not

spread hides on the slaughter floor. \u2022 Ensure employees maintain proper hygiene practices to prevent carcass contamination and the creation of insanitary conditions. Do not touch the carcass with soiled hands, tools, or garments.", "23 What are best practices during weasand rodding? This is the point in the process where the establishment uses a metal rod to free the esophagus (weasand) from the trachea and surrounding tissues. Weasand meat may be salvaged from the remainder of the GI tract for use in raw ground beef production. Typically, the weasand is closed (i.e., tied) to prevent rumen spillage. If the weasand is not closed, ingesta and ruminal content can result in carcass contamination. It is important, at this point in the process, that contamination is not transferred from the exterior of the carcass to the interior or onto the weasand. Also, if during the rodding process the GI tract is punctured, ingesta content can contaminate the carcass interior and exterior. Alternatively, establishments could send weasand meat for cooking or other full-lethality treatment (e.g., high pressure processing or irradiation). Best Practices during Weasand Rodding \u2022 Close the esophagus to prevent leakage of rumen contents. \u2022 Change or sanitize the weasand rod between each carcass. \u2022 Ensure that employees maintain proper hygiene practices to prevent carcass contamination and the creation of insanitary conditions. Do not touch the carcass with soiled hands, tools, or garments. \u2022 Clean and chill the weasand quickly to limit contamination and pathogen multiplication. Best Practices during Bunging \u2022 Drop the bung during the final part of rumping or at a time that minimizes cross contamination to the carcass. \u2022 Bag and tie off bungs to prevent carcass contamination. \u2022 Maintain proper employee hygiene practices to prevent carcass contamination and the creation of insanitary conditions. Do not touch the carcass with soiled hands, tools, or garments. \u2022 Apply a validated decontamination process to the local area (e.g., steam vacuum) or antimicrobial treatment to the entire carcass at this point or a point later in the process, that is effective in reducing the presence or counts of microbial contaminants.", "24 What are best practices during head removal? This is the point in the slaughter process where the head is removed from the carcass. It is important to maintain sanitary conditions because cross contamination can occur if the head comes into contact with insanitary heads, equipment, or employee hands or garments. Best Practices during Head Removal \u2022 Maintain adequate separation between skinned heads, carcasses, the floor, and fixed objects. \u2022 While skinning the head, the head Skinner should sterilize the knife as frequently as necessary to prevent cuts from cross-contaminating the head. \u2022 Remove heads as soon as possible after skinning to further reduce contamination exposure. \u2022 Sanitize the neck breaker or knives as necessary. \u2022 Prevent contamination with rumen contents during head removal. This can usually be accomplished by tying the esophagus and then pulling the head sharply to the side as the gullet is cut. Removal of rumen content contamination is difficult because of its finely textured character, which makes prevention even more important. \u2022 Remove the horns, all pieces of hide and eardrums from each head in a manner to minimize contamination. \u2022 Clean the equipment used to hold heads for trimming and\or dehorning between each head. Disinfect the equipment after use on each suspect, retained or other obviously diseased head. \u2022 Prevent cross-contamination of other heads or adjacent carcasses and limit airborne contaminants. \u2022 Thoroughly flush the oral and both nasal cavities before washing the outer surfaces of each head. \u2022 Head hooks in washing cabinets should be removable to allow for cleaning and sterilizing or sanitizing. Clean hooks between each use and sterilize hooks

after handling suspect, retained, or obviously diseased heads. If the head hooks are not removable, the equipment should be designed for in-place sterilization and equipped with an integral thermometer or other temperature-measuring device. \u2022 Have procedures in place to make sure heavily contaminated heads do not cross contaminate other heads in head wash cabinets (e.g., shut off the cabinet before heavily contaminated heads enter the cabinet and recondition or discard affected product after inspection.) \u2022 Clean and sterilize head inspection racks after each use involving a retained head. Since this is impractical to accomplish with hooks installed on a continuous chain, provide all such installations with a suitable wash cabinet or other device that will clean and sterilize each hook prior to its subsequent use."<sup>25</sup> What are best practices during brisket opening? This is the point in the process where the brisket is split (i.e., cut along the centerline) to facilitate the easy removal of the thoracic viscera. The thoracic cavity is entered blindly and there is no way of knowing if abscesses or other pathological conditions are present. Therefore, the saw, or other instrument used to split the brisket, should be disinfected after each use, making sure to remove remnant tissue from the saw. Best Practices during Head Removal (Continued) \u2022 The minimum temperature for hot water sterilization is 180\u00b0F. Use an integral thermometer or other temperature-measuring device for continuous monitoring to ensure a minimum temperature of 180\u00b0F is met for hot water sterilization. Maintain proper employee hygiene practices to prevent carcass contamination and the creation of insanitary conditions. Do not touch the head with soiled hands, tools, or garments. \u2022 Address specified risk materials in accordance with 9 CFR 310.22. \u2022 At this point apply to the head a validated decontamination process (e.g., hot water wash) or antimicrobial treatment that is effective in reducing the presence or counts of microbial contaminants. Best Practices during Brisket Opening \u2022 Clean and sanitize the brisket saw and knife between each carcass and ensure the GI tract is not punctured. \u2022 Ensure that employees maintain proper employee hygiene practices to prevent carcass contamination and the creation of insanitary conditions. Do not touch the carcass with soiled hands, tools or garments. \u2022 Apply a validated decontamination process to the local area (e.g., steam vacuum) or antimicrobial treatment to the carcass at this point or a point later in the process that is effective in reducing the presence or counts of microbial contaminants."<sup>26</sup> What are best practices during evisceration? This is the point in the process where the removal of the viscera (e.g., the edible offal that includes the heart, intestines, paunch, liver, spleen and kidneys when presented with viscera) occurs. The actual removal of the viscera from the carcass is a critical phase of the dressing operation. Care should be taken to avoid cutting or breaking the paunch and intestines because the GI tract can contain pathogens. If the viscera are not handled properly, or if employee hygiene practices are not being followed, contamination of the carcass and edible offal can occur. What are the best practices during head and cheek processing? This is the point in the process where the meat is removed from the head and cheek. This meat can be used in the production of raw beef products, including ground beef. It is important for the establishment to maintain sanitary conditions when removing meat from the head and cheeks. Best Practices during Evisceration \u2022 The boot cleaning compartment should be conveniently located and constructed so as to prevent splash of contaminants onto carcasses or viscera. Thoroughly clean and disinfect contaminated footwear, apron, or knife. \u2022 Thoroughly clean and disinfect the viscera inspection truck, especially if it becomes soiled with visceral contents (e.g., feces, ingesta) or contaminated with

purulent material or viscera from a condemned carcass. To prevent fat buildup on the metal pluck pan or paunch and viscera portion of the inspection truck, periodically clean with hot water. Prevent cross contaminating product or equipment when rinsing a viscera inspection truck. \u2022 Ensure that employees maintain proper hygiene practices to prevent carcass contamination and the creation of insanitary conditions. Do not touch the carcass with soiled hands, tools, or garments. \u2022 Address specified risk materials in accordance with 9 CFR 310.22. \u2022 Apply a validated post-evisceration decontamination or antimicrobial treatment to the entire carcass and edible offal." , "27 What are best practices during carcass splitting? This is the point in the process where carcasses are split vertically into two halves. Prior to splitting, the establishment should remove all contamination, bruises, grubs, and tissue damaged by grubs from the midline area of the back. This is necessary to prevent spreading these contaminants to bone and other surfaces by the saw. Best Practices during Head and Cheek Processing \u2022 Properly maintain and clean knives. \u2022 Provide adequate separation or use compartments or shields to prevent cross contamination of heads. \u2022 Ensure that employees maintain proper hygiene practices to prevent head contamination and the creation of insanitary conditions. Do not touch heads with soiled hands, tools or garments. \u2022 Address specified risk materials in accordance with 9 CFR 310.22. \u2022 Quickly chill head and cheek meat to limit pathogen multiplication. \u2022 Apply any validated decontamination process or antimicrobial intervention treatments to the head and cheek meat that are effective in reducing the presence or counts of microbial contaminants after lymph node incision. Alternatively, send head and cheek meat for cooking or other full-lethality treatment (e.g., high pressure processing or irradiation). \u2022 Conduct microbiological testing (e.g., STEC) for process control to assess the effectiveness of the establishment's sanitary dressing procedures and any antimicrobial intervention treatments that are applied to the head and cheek meat as these products may undergo different interventions than the carcass." , "28 Best Practices during Carcass Splitting \u2022 Remove organic material, bruises, grubs, and tissue damaged by grubs from the midline area of the back prior to splitting to reduce potential contamination to the split saw, surrounding tissues, and other surfaces. \u2022 Sanitize saws and knives as necessary. Disinfect the splitting saw after each use on suspect, retained, or obviously diseased carcasses. \u2022 Allow adequate separation between carcasses to limit carcass-to-carcass contact. \u2022 Ensure that employees maintain proper hygiene practices to prevent carcass contamination and the creation of insanitary conditions. Do not touch the carcass with soiled hands, tools, or garments. \u2022 Address specified risk materials in accordance with 9 CFR 310.22. \u2022 When splitting is done at the half-hoist position, take measures to prevent the neck and foreshanks from contacting the floor. If necessary, install a surface that can be sanitized so the neck and foreshanks do not contact the floor. \u2022 Apply any validated decontamination or antimicrobial intervention treatments to the carcass at this point or a point later in the process that are effective in reducing the presence or counts of microbial contaminants. KEY QUESTION Carcass Wash Cabinets Question: How do establishments use carcass wash cabinets appropriately? Answer: Develop and implement measures, such as those listed directly below, to prevent spreading contamination to adjacent carcasses. \u2022 Remove all visible contamination before carcasses enter the cabinet. \u2022 Prevent overspray of water from the cabinet onto adjacent carcasses. \u2022 Prevent carcasses with conditions such as open abscesses, septic bruises, or the presence of parasites and

parasitic lesions from entering the cabinet. Wash from the top of the carcass in a downward direction so that contaminants gravitate away from the clean areas. Have procedures in place to make sure heavily contaminated carcasses do not cross contaminate other carcasses (e.g., shut off the cabinet before heavily contaminated carcasses enter the cabinet and recondition or discard affected product after inspection).", "29 What are the best practices during chilling? This is the point in the process where the temperature of the carcass and parts is reduced. Temperature control and sanitation measures ensure the microbial load reductions affected by the interventions are maintained. Temperature control limits pathogen multiplication and sanitary measures prevent re-contamination. Conduct on-going verification to ensure that any re-circulated hot water used in the cabinet meets 9 CFR 416.2 (g)(3). This regulation states that, Water, ice, and solutions used to chill or wash raw product may be reused for the same purpose provided that measures are taken to reduce physical, chemical, and microbiological contamination to prevent contamination or adulteration of product. Reuse that has come into contact with raw product may not be used on ready-to-eat product.\u201d \u2022 Have procedures in place to prevent carcasses identified with U.S. Suspect or Retained tags from entering the cabinets or have procedures in place to prevent cross-contamination of adjacent carcasses (e.g., shut off the cabinet before U.S. Suspect or Retained carcasses enter the cabinet and recondition or discard affected product). NOTE: Establishments can wash U.S. Suspects in these cabinets only with permission of the USDA Public Health Veterinarian (PHV) and in consideration of whether the design of the cabinet prevents cross-contamination of other carcasses. \u2022 Address potential hazards associated with water reuse in non-food processing areas to prevent the creation of insanitary conditions.", "30 Best Practices during Chilling Note: The times and temperatures listed on this page are based upon past industry practices and are not regulatory requirements. Establishments may select other times or temperatures if they maintain scientific support for the selection of those parameters. \u2022 Begin carcass chilling within approximately one hour after bleed-out to limit pathogen multiplication. \u2022 Begin chilling variety meats as quickly as possible after removal from the carcass to limit pathogen multiplication. \u2022 Implement temperature control and sanitation procedures to maintain the microbial reductions achieved by the antimicrobial intervention treatments. \u2022 Define and monitor refrigeration parameters so that carcasses reach a temperature of 40\u00b0F (4.4\u00b0C) or less within 24 hours and so that this temperature is maintained for all products. Take and record carcass temperature from 5 randomly selected carcasses in various cooler locations, usually 1 mm under fascia on the inside round (see Appendix 4, Chilling of Carcasses). \u2022 Maintain finished product storage areas at 40 \u00b0F or lower or have other supporting documentation for the temperature limit chosen. \u2022 Provide adequate distance between carcasses, walls and equipment to prevent cross contamination and allow for efficient air circulation to prevent or minimize condensation. \u2022 Ventilate coolers with negative-pressure systems to prevent cross contamination from airflow from slaughter operations. \u2022 If carcasses are held longer than 7 days in the cooler before fabrication, maintain scientific support for cooler parameters which may include temperature, humidity, and air flow. \u2022 Transport carcasses for hot boning (deboned before chilling) to the boning areas directly from the slaughter department. Do not delay boning. Maintain the boning room environmental temperature at 50 \u00b0F (10 \u00b0C) or lower. \u2022 At this point apply any validated decontamination or antimicrobial

intervention treatments to the carcasses and variety meats to reduce microbiological contamination. \u2022 Ensure that employees maintain proper hygiene practices to prevent the creation of insanitary conditions (e.g., touching the carcass with soiled hands, tools, or garments). \u2022 Prevent cross-contamination from airflow during slaughter operations. \u2022 Establish traffic patterns to eliminate movement of personnel, pallets, and refuse containers between slaughter and further processing. If employees must work in both areas, have procedures in place that require the employees to change outer and other soiled clothing, wash and sanitize hands, and clean and sanitize footwear before moving from slaughter to further processing areas.", "31 What are best practices during carcass fabrication? This is the point in the process where the carcass is broken down into primal and subprimal cuts and trimmings. Temperature control limits pathogen multiplication and sanitary measures prevent re-contamination. What are best practices during packaging, product storage, and product transport? These are the points in the process where products are packaged, stored, and transported for further distribution. Temperature control limits pathogen multiplication while sanitary measures prevent product re-contamination. Best Practices during Carcass Fabrication \u2022 Implement temperature control and sanitation procedures to maintain the microbial reductions achieved by the antimicrobial intervention treatments. \u2022 Maintain processing room temperature at 50\u00b0F (10\u00b0C) or lower. \u2022 Provide for efficient air circulation to prevent or minimize condensation. \u2022 Ventilate coolers with negative-pressure systems to prevent cross contamination from airflow from slaughter operations. \u2022 Ensure that employees maintain proper hygiene practices to prevent the creation of insanitary conditions. Do not touch the carcass with soiled hands, tools or garments. \u2022 Clean and sanitize knives, saws, slicers, and other food contact surfaces as frequently as necessary to prevent the creation of insanitary conditions. \u2022 Establish traffic patterns to eliminate movement of personnel, pallets, and refuse containers between slaughter and further processing. If they must work in both areas, have procedures in place so employees change outer and other soiled clothing, wash and sanitize hands, and clean and sanitize footwear before moving from slaughter to further processing areas. \u2022 At this point in the process, employ any validated decontamination or antimicrobial intervention treatments that are effective in reducing the presence or counts of microbial contaminants on the carcasses. \u2022 Conduct microbiological testing (e.g., STEC) of BMT as per the establishment's HACCP Plan, Sanitation SOPs, Good Manufacturing Practices (GMPs), or other prerequisite programs, to verify pathogens have been eliminated.", "32 Beef Slaughter Interventions How do antimicrobial intervention treatments fit into the HACCP regulatory framework? Establishments implement antimicrobial interventions as needed to reduce STEC and Salmonella. The HACCP regulations require establishments to provide scientific support for their interventions and to implement their interventions according to that support. 9 CFR 417.2(a) requires that an establishment identify any food safety hazards that might occur in the production process, assess which hazards are reasonably likely to occur, and develop measures to prevent, eliminate, or reduce to an acceptable level those hazards. The establishment must maintain documents to support the decisions it makes during its hazard analysis (9 CFR 417.5(a)(1)). Establishments may incorporate the use of interventions in their HACCP plan, sanitation SOPs, or other prerequisite program. Establishments may incorporate the use of interventions in their HACCP plan and apply the intervention as a CCP to control hazards that are reasonably likely to

occur (9 CFR 417.2(c)(3)). Alternatively, an establishment may determine that a hazard is not reasonably likely to occur because the establishment maintains preventive measures as part of a prerequisite program that prevents the hazard from occurring. In either case, the establishment should identify the critical operating parameters for any antimicrobial interventions used in its Best Practices during Packaging, Product Storage and Product Transport \u2022 Implement temperature control and sanitation procedures to maintain the microbiological reductions achieved by the antimicrobial intervention treatments applied during the slaughter process. \u2022 Maintain storage room and transportation vehicles at 40\u00b0F (4.4\u00b0C) or lower. \u2022 Maintain the average internal meat temperature during storage at 40\u00b0F (4.4\u00b0C) or lower. \u2022 Monitor and record environment and product temperature during product storage and product transport. \u2022 Provide for efficient air circulation to prevent or minimize condensation. \u2022 Prevent contamination from airflow, traffic, people, and other environmental sources. \u2022 Ensure employees maintain proper hygiene practices to prevent the creation of insanitary conditions. Do not touch the product with soiled hands, tools or garments.", "33 supporting documentation. HACCP plans control hazards; prerequisite programs (including sanitation SOPs) prevent hazards from entering the establishment\u2019s food safety system. What are critical operating parameters and how do they fit into the establishment\u2019s HACCP system? As described in the FSIS Compliance Guideline HACCP Systems Validation, critical operating parameters are the specific conditions (e.g., time, concentration, temperature, full product, or carcass coverage) that the intervention must operate under for it to be effective. The establishment should incorporate the critical operating parameters into its critical limits if the establishment applies the intervention as part of a CCP. Alternatively, the establishment should incorporate the critical operating parameters into appropriate procedures if it implements the intervention as part of a sanitation SOP or other prerequisite program. To be effective, the process procedures should be consistent with the critical operational parameters in the scientific support. If the establishment\u2019s specific parameters do not closely match the scientific documentation, the establishment should consider developing a decision-making document that explains the scientific rationale for why the different level would not affect the efficacy of the intervention or process. Why is it important for establishments to incorporate antimicrobial interventions into their HACCP systems? Despite good slaughter and dressing practices, contamination of carcasses can occur. Thus, the use of effective antimicrobial intervention strategies is an important component of an integrated food safety system. FSIS recommends that establishments implement antimicrobial interventions throughout the slaughter and fabrication processes, specifically just after points in the process where carcasses are most vulnerable to contamination (e.g., during hide removal and post-evisceration), as part of a multi-hurdle approach. Further, FSIS recommends that establishments identify the typical microbial loads introduced into their slaughter process and develop a multi-hurdle approach that is designed to reduce microbial hazards to acceptable levels. FSIS also recommends that establishments account for the higher prevalence season for STEC (April - October) and make necessary adjustments to their food safety system to address STEC. Can dry aging be used as an intervention to reduce STEC in a HACCP system? Yes. Dry aging can be used as an intervention to reduce pathogens, including STEC. It is the process of reducing the bacterial load on the carcass through surface desiccation. This process", "34 is not to be confused with the product

quality process of dry aging, which is used to improve tenderness and\or flavor. To desiccate the surface of the carcass to reduce pathogens, the carcasses are maintained in a cooler for a time, usually days or weeks, under specific environmental conditions that may vary, depending upon the support used by the establishment. Proper temperature, air flow, and relative humidity are needed to desiccate the surface of the carcass and minimize mold growth. Using the scientific support provided in Tittor et al., an establishment can develop an aging program as an intervention to reduce STEC to nondetectable levels. In this study, beef lean and beef fat were inoculated with multiple strains of E. coli O157:H7. The dry aged samples were suspended in a cooler that had the following parameters: 37.4\u2070F, 80% relative humidity and 0.0 to 0.25 m\s air velocity. A decrease in E. coli O157:H7 14 days to 28 days in lean tissue and from 7 days to 28 days in fat tissue was reported in the study. These specific parameters could be implemented, and an establishment could validate that they are able to consistently meet the critical operating parameters from the study. NOTE: FSIS does not object to establishments using the Tittor et al. final report as support until a peer reviewed journal article is published. Alternately, the establishment may implement other specific parameters for dry aging using other scientific supporting documentation or additional in-house validation data to support the alternative procedures, provided the same or better results as Tittor et al. are achieved. The FSIS Compliance Guideline HACCP Systems Validation describes how establishments can conduct in plant validation monitoring. In addition to the critical operating parameters, establishments using dry aging to address pathogens may need to monitor for mold growth and develop procedures to reduce the growth of mold and remove mold from the carcass when growth occurs. FSIS has reviewed the article by Algino, et al. (2007) and determined that this article does not provide sufficient scientific support alone for the use of dry aging beef carcasses as an effective intervention to reduce STEC to non-detectable levels. Algino R.J., Ingham S.C., and Zhu J. 2007. Survey of Antimicrobial Effects of Beef Carcass Intervention Treatments in Very Small State-Inspected Slaughter Plants. Journal of Food Science. Vol 72: 173-179 FSIS made this determination because the authors used indicator organisms, (e.g., generic E.coli) as a surrogate for E.coli O157:H7 or non-O157 STEC. FSIS is not aware of any supporting documentation that demonstrates a strong correlation to support the use of generic E. coli testing as a surrogate for E.coli O157:H7 or non-O157 STEC. If an establishment chooses to use this article as support for its dry aging intervention, additional data (e.g., microbiological data gathered in-plant) would be needed to support the dry aging intervention to reduce STEC to a non-detectable level.,"35 How do establishments identify critical operating parameters? As explained in the FSIS Compliance Guideline HACCP Systems Validation, establishments are required to identify and maintain supporting documentation that closely matches their interventions and should identify, implement and monitor the critical operating parameters from the scientific supporting documentation relevant to their interventions. Critical operating parameters are the specific conditions under which an intervention must be used for it to be effective. These critical operating parameters should be incorporated into the establishment\u2019s HACCP system (including prerequisite programs). As part of validation, establishments must also maintain documentation showing that they have effectively implemented these parameters in their operations. The critical operating parameter may or may not be incorporated into the establishment\u2019s HACCP plan as a critical limit for a CCP. If an establishment uses a scientific study as its supporting documentation, the critical

operating parameters from the scientific study should match the intervention implemented by the establishment as closely as possible. In some circumstances, establishments may be able to support using critical operating parameters that are different from those in its supporting documentation (e.g., different concentrations of antimicrobial agents or temperature of the antimicrobial). In cases where critical operating parameters are different from the supporting documentation, establishments should provide justification to support that the critical operating parameters chosen are at least as effective as those in the supporting documentation. This justification is needed because deviating from the critical operating parameters in supporting documentation may not always provide an equally effective result. For example, antimicrobial agents may only be effective within a certain concentration range; above or below that the efficacy may decrease. In addition to ensuring that the concentration range of interventions chosen are at least equally effective, establishments should ensure the concentrations are also safe and suitable. FSIS Directive 7120.1, Safe and Suitable Ingredients used in the Production of Meat, Poultry, and Egg Products is updated monthly and includes a list of antimicrobial agents that are safe and suitable for certain products under certain conditions of use. Establishments have flexibility in how they verify that they are implementing the critical operating parameters for applying antimicrobial interventions.

**Key Points**  
Establishments are required to maintain supporting documentation that closely matches their interventions, identify the critical operating parameters that are necessary for the interventions to be effective, and maintain documentation showing that they have effectively implemented their interventions so that they meet these critical operating parameters.<sup>36</sup> What are examples of critical operating parameters for applying antimicrobial or hot water interventions on carcasses and fabricated raw beef products? Examples of critical operating parameters for applying antimicrobial or hot water interventions to carcasses and fabricated raw beef products include the following: Product coverage pH Contact time Dwell time Temperature Pressure Equipment settings or calibration Concentration There are simple verification procedures an establishment can use to ensure its antimicrobial intervention achieves carcass/product coverage. For example, the establishment could apply the intervention using fluorescein dye instead of the antimicrobial to evaluate carcass/product coverage. Alternatively, the establishment could apply paper towels or an edible spray cream before the intervention and evaluate the carcass/product for full coverage after the intervention. FSIS developed the FSIS Compliance Guideline HACCP Systems Validation to assist establishments in complying with initial validation requirements that address validation of critical operating parameters for antimicrobial or hot water interventions. What are examples of antimicrobial interventions? Antimicrobial intervention strategies are designed to reduce microbial contamination on carcasses and parts and usually involve the application of organic acids, hot water, steam, removal by physical means, such as knife trimming, or a combination of these, in a sequence, referred to as a multi-hurdle approach. The integration of established intervention methods, such as knife trimming, in combination with other antimicrobial decontamination methods, such as steam vacuuming, steam pasteurization cabinets, acid or hot water spray washing systems, can help to improve the microbial safety of beef carcasses immediately post-slaughter. Dry aging can be used as an intervention as part of a multi-hurdle approach or as a stand-alone intervention. Establishments should apply these interventions according to their scientific support. The table below shows the antimicrobial

interventions that can be used during the beef slaughter process. Intervention Type

**Intervention Description**

Hide-on carcass washes Hide-on carcass washes are an effective means to significantly reduce bacterial populations on the hide, a significant source of contamination in slaughter operations. Hide-on carcass washes commonly used include<sup>37</sup>, hypobromous acid; sodium hydroxide and a proprietary surfactant with a sodium hypochlorite rinse; and water washes with chlorine. Steam vacuum systems The hot water sprayed onto a carcass kills bacteria and detaches contamination, such as ingesta or feces, which is then vacuumed off. Many establishments utilize the steam vacuum system at multiple points in the slaughter process. For example, there may be a steam vacuum location after each part of the carcass de-hiding process. Pre-evisceration wash and final carcass organic acid wash The pre-evisceration wash consists of using a carcass spray immediately after hide removal and serves to remove bacteria before they have the opportunity to attach themselves to the carcass surface and begin growing. The final carcass organic acid rinse provides a significant kill step for any bacteria that remain on the carcass surface at the end of the slaughter process. This intervention is commonly applied after the slaughter process is complete and before the carcasses enter the cooler. The organic acids commonly used are acetic and lactic, although citric acid is also approved for this purpose. The concentration of the organic acid is normally between 1.5% and 2.5% and can be as high as 5% in the case of lactic acid. Hypobromous acid is another effective acid that is commonly used in the industry. Organic acids may be applied as a mist, fog, or a small droplet rinse. Studies have shown that washing followed by an organic acid rinse is significantly more effective in reducing bacterial numbers than washing alone.

Pre-evisceration and final carcass hot water washes High temperature water sprayed on the carcass (hot water rinse) as a preevisceration wash and a post-evisceration wash prior to chilling have been shown to be effective in substantially reducing STEC and Salmonella.

**Steam pasteurization**

Steam pasteurization is a process in which the carcasses are placed in a slightly pressurized, closed chamber at room temperature and sprayed with steam that blankets and condenses over the entire carcass, raising the surface temperature (generally to 185°F) and killing up to 95-99% of all bacteria. Carcasses are then sprayed with cold water.

**Dry aging**

Dry adding intervention reduces pathogens on the surface of the carcass through desiccation under specific environmental conditions. Why is it important for establishments to conduct verification testing? FSIS requires that establishments perform ongoing verification activities to ensure that their food safety systems are functioning as intended (9 CFR 417.4(a)(2)) and to support decisions made in their hazard analyses, including their sampling locations (9 CFR 417.2 and 417.5(a)(1)). FSIS recommends that establishments incorporate statistical process control procedures into their testing programs to assess the effectiveness of their controls for preventing contamination during slaughter and dressing operations and to verify that they are reducing pathogen levels, including STEC to below detectable levels. Establishments are required to support the frequency of their verification activities (9 CFR 417.5(a)(2)).

Establishments can use microbial test results to support decisions made in their HACCP systems and to verify that their food safety system is functioning as intended. Establishment sampling and testing programs can be supplemented with other types of verification activities associated with the production of other raw ground beef and patty components.<sup>38</sup>

**Beef Slaughter Processing Deficiencies**

What are common deficiencies that FSIS identified in beef slaughter establishments? FSIS conducted a review of food safety assessments (FSAs) and onsite visits to

beef slaughter establishments with a history of multiple positive STEC results from FSIS testing. During the review, FSIS identified the following common deficiencies: \u2022 Inadequate sanitary dressing; \u2022 Ineffective implementation of antimicrobial intervention; and \u2022 Failure to use microbial data appropriately in decision making. What are examples of sanitary dressing deficiencies FSIS observed repeatedly at beef slaughter establishments? FSIS identified that some beef slaughter establishments repeatedly failed to do the following relative to sanitary dressing: \u2022 Implement a comprehensive sanitary dressing program that includes: written procedures designed to prevent contamination from occurring throughout the process, adequate employee training concerning these written procedures, and a management commitment to the program. \u2022 Verify that the sanitary dressing procedures are performed as written, effective, and consistently performed. \u2022 Properly design facilities and equipment to: prevent carcasses from contacting each other NOTE: Generic E. coli data required under 9 CFR 310.25 should not be used to verify whether the establishment\u2019s HACCP system is addressing STEC. Differences in laboratory method sensitivity demonstrate that STEC can still be recovered from a sample when below the limit of detection of direct plate generic E. coli methods. Further, detectable levels of generic E. coli do not mean STEC specifically is present. Therefore, testing for generic E. coli is not an effective verification procedure for assessing STEC controls. Key Point With any antimicrobial intervention, carcass\product coverage is important.", "39 or non-food contact surfaces, prevent overspray of antimicrobial treatments or aerosolization of particulate matter, and allow adequate visualization of dressing procedures (e.g., through proper lighting or access). \u2022 Perform robust sampling and testing, according to their supporting documentation, to obtain reliable results to verify their slaughter operation is addressing hazards. \u2022 Adequately respond to FSIS or establishment positive test results with effective and sustainable corrective actions that identify the cause, eliminate it and prevent recurrence. \u2022 Apply antimicrobial interventions according to supporting documentation. Examples of Sanitary Dressing Deficiencies Cutting through the hide and into the carcass without sanitizing knives, gloves, and equipment, resulting in carcass contamination. Note how grossly contaminated the hide is, further increasing the risk of contamination. Proper hide removal is a critical step in preventing carcass contamination and the creation of insanitary conditions.", "40 Inadequately sanitizing knives, gloves, and equipment resulting in carcass contamination along pattern lines during hide removal (part 1 of 2).", "41 Inadequately sanitizing knives, gloves, and equipment resulting in carcass contamination along pattern lines during hide removal (part 2 of 2).", "42 Contaminated carcass as a result of contact with non-food contact surfaces. (circled in yellow). Carcass contamination from the hide flaps during hide removal. This photo shows hide flaps that have curled under after hide removal and are contaminating the carcass.", "43 Splatter contamination resulting from improperly adjusted hide pullers. Improperly adjusted hide pullers can cause carcass contamination.", "44 Bagged bung contacting hide resulting in carcass contamination. This photo shows the bagged bung contacting the hide (yellow arrow) while the employee is tying the bagged bung. Bunging performed before the hide of the rump is removed results in contamination of the carcass. This occurs because the bagged bung will likely contact the hide and later contaminate the carcass as the gastrointestinal tract is removed during evisceration and the bagged bung is pulled through the pelvic inlet. Failing to bag and tie the bung. The contaminated bung is contacting the exposed carcass (yellow arrows). When

establishments apply hot water or antimicrobial interventions to an exposed bung, they may further spread contamination.", "45 Contamination during evisceration. Punctured paunch and intestines during evisceration causing carcass contamination with ingesta (second photo).", "46 What are examples of antimicrobial intervention deficiencies FSIS has observed repeatedly at beef slaughter establishments? FSIS identified that some beef slaughter establishments repeatedly failed to do the following: \u2022 Apply antimicrobial interventions according to their supporting documentation; \u2022 Identify critical operational parameters in their supporting documentation; \u2022 Incorporate the critical operational parameters into their HACCP system; and \u2022 Implement the antimicrobial treatments so that critical operational parameters are met. Examples of Antimicrobial Intervention Implementation Deficiencies Cross-contamination during antimicrobial intervention treatment. \u2022 Cross contamination of heads from carcass intervention overspray. (Water sprayed onto the carcass in the direction of the arrows, water spray seen within the yellow oval.) \u2022 Cross contamination (not shown in image) when employees spray equipment, the floor, and other surfaces, establishments do not take appropriate precautions to prevent overspray from contacting carcasses. \u2022 Carcasses with visible contamination entering a wash cabinet or when manual application of water or antimicrobial sprays occurs on visibly contaminated carcasses, this can result in cross contamination. .", "47 Failing to achieve full carcass coverage with intervention, thus reducing the intervention's effectiveness. This photo shows the practice of suspending a carcass from a single hook, which prevents antimicrobial and hot water interventions from achieving full carcass\product coverage. Ensuring that the entire carcass surface is treated, is necessary for the intervention to operate effectively and as intended. Failing to achieve full product coverage with intervention, thus reducing the intervention's effectiveness. Product coverage is essential for the intervention to be effective. The top photo shows that the arc of the spray nozzles (inside each yellow line) is not sufficient to reach product on the sides of the conveyor belt (yellow arrows). Both pictures show that the spray intervention is being applied only to one side of the trim. These pictures also show product that is folded on top of itself so that the intervention is not applied to all product surfaces (the top photo shows the trim is piled up and the bottom photo shows that each piece has a single fold).", "48 What are examples of FSIS observations regarding establishments that fail to properly use microbial data in decision-making? Some establishments that had multiple STEC positive samples from FSIS testing failed to properly assess the impact the test results had on their slaughter operations. Test results reflect the effectiveness of the establishment\u2019s slaughter operation, including the effectiveness of its sanitary dressing procedures and antimicrobial treatments. In response to the test results, establishments failed to take meaningful corrective actions designed to identify and eliminate the cause of the positive test results and prevent recurrence. The scope of the corrective actions was limited to ensuring that lots contaminated with STEC received appropriate disposition. Corrective actions were not aimed to improve the design and implementation of slaughter operations. Additionally, some establishments did not conduct robust sampling, which could have provided them meaningful information concerning the effectiveness of their slaughter operations. In some situations, establishments had designed rigorous sampling programs but were not implementing them effectively. Specifically, establishments were not properly collecting N60 samples. Sample slices were smaller in size than the N60 method requires. Additionally, external surfaces were not

targeted for N60 sampling and, in some cases, the tissues were thicker, which reduces the sensitivity of the method. Establishments that conduct proper robust sampling have ongoing information concerning the effectiveness of their slaughter operations and can respond to the microbial data to improve their operations. FSIS recognizes some establishments may utilize other sample collection methods (e.g. surface sampling or core shaving methods) that have received a No Objection from FSIS as being at least equal to the N60 sample collection method for the detection of low levels of STEC.", "49 APPENDICES", "50 Appendix 1. Establishment Self-Assessment Checklist for Sanitary Dressing Procedures Live Receiving\Holding Questions Yes No Comment Do we take measures, such as periodic cleaning of the unloading areas and pens, to reduce the contamination of animals during unloading and holding? Do we apply a bacteriophage to cattle? Do we conduct cattle washing? Do we have data showing that washing decreases incoming bacterial loads? Do we monitor the cattle washing process to ensure that contamination is minimized? Do we use water mist as a means to reduce airborne dust and dirt particles in the holding area? Do we use a \u201cmud-scoring\u201d system to identify cattle that may present an increased likelihood of contamination during hide removal? Do we react to cattle showing increased loads of contamination on their hides? Do we determine the incoming bacterial load on animals? Do we consider differences in the age or type of cattle we receive (e.g. veal calves, sale barn cattle, feedlot cattle, hide condition) and does that indicate a concern related to pathogen load that we address?", "51 Sticking Questions Yes No Comment Do we use the smallest cut possible to accomplish the bleeding? Do we use a two-knife system for sticking and clean the hand between sticking each carcass? Do we sanitize knives between animals? Do we employ any validated decontamination or antimicrobial intervention treatments at this point in the process that are effective in reducing the presence or counts of microbial contaminants?", "52 Hide Removal Questions Yes No Comment Do we use a validated hide-on carcass wash? Do we use a two-knife system for the entire de-hiding process? Do we remove the udder in a manner to prevent contamination of the carcass with milk, and to prevent contamination of the exposed carcass by the hide, or by a soiled knife or employee hand? Do we remove visible contamination from the pattern (cut line)? Do we trim or steam vacuum pattern lines? Do we prevent wicking of moisture into hide openings? Are carcasses or parts of carcasses touching or banging into each other? Are there excessive turns or switchbacks in the de-hiding line such that hide-on cattle are passing by carcasses with the hide partially removed? Do we have shields between the carcasses and hide puller to minimize potential contamination? Do we remove the tail switch when using the hide puller to minimize the possibility that contaminants can become airborne from splattering or flapping the hide? Is the hide puller causing carcass contamination or cross contamination of adjacent carcasses? If we use a cradle, are live animals in such close proximity to the partially dressed animal on the cradle that airborne contamination is a concern? If we use mechanical hide pullers, do they pull away from the carcass (e.g., downward or backward and not upward), thereby reducing the potential for contamination from drip splatter? When the hide is pulled from the carcass, does it splatter the dressed carcass or adjacent carcasses? If employees are handling carcasses during hide pulling, does the hide cross-contaminate the carcass or employees\u2019 equipment and clothing? If so, is the contamination removed from employee\u2019s equipment and clothing before continuing dressing procedures? Does the exterior side of the hide touch or slap the carcass as the hide is removed?", "53 Do we maintain clean mechanical

hide puller contact points with the hide, hands, and garments of the employees handling the hide and carcass, and knives and other equipment contacting the de-hided carcass? Do our employees maintain proper employee hygiene practices to prevent the creation of insanitary conditions (e.g., touching the carcass with soiled hands, tools, or garments)? In the process of reflecting the hide from the carcass, do our employees intentionally or accidentally cut through the hide? Do we clean and sanitize knives, air knives, or other equipment and clothing before proceeding to reflect the hide away from the carcass any further? Do we allow for adequate distance between carcasses throughout the slaughter dress process to minimize carcass-to-carcass contact and cross contamination? Do we allow adequate separation of carcasses, parts, and viscera during dressing? This would include at switchbacks (sharp turns) and areas where carcasses in the hide-on area pass by in close proximity to carcasses in the hide-off area. Are the hides (especially of feet, legs, tails) of carcasses in the hide-on area cross contaminating equipment and clothing of the employees (aprons, scabbards, steels, gloves)? If so, do we clean and sanitize contaminated equipment or clothing? Do we apply a carcass wash cabinet at this point or any other point in the slaughter process? If so, do we ensure that cabinets do not spread contamination to adjacent carcasses? Do we control overspray from the carcass wash cabinet? Do we address conditions such as open abscesses, septic bruises, or the presence of parasites and parasitic lesions before carcasses enter the carcass wash cabinet? Do we address pooling of water around the anus of the carcass prior to dropping the bung? Do we ensure that carcasses with excessive contamination do not cross contaminate other carcasses (i.e., create an insanitary condition)? Do we ensure that carcasses identified with U.S. Suspect or Retained tags, that should be removed from the slaughter line at a further point in the process, do not enter the carcass wash cabinets unless measures are in place to prevent cross contamination of equipment or other carcasses? \*U.S. Suspects are to be washed in these cabinets only with permission of the PHV, and in consideration of whether the design of the cabinet prevents cross contamination of other carcasses. Do we employ any validated decontamination or antimicrobial intervention treatments at this point in the process that are effective in reducing the presence or counts of microbial contaminants?", "54 Bunging Questions Yes No Comment Do we put plastic bags and ties on the bung in a sanitary manner? Do we maintain proper employee hygiene practices to prevent the creation of insanitary conditions (e.g., touching the carcass with soiled hands, tools, or garments)? Do we employ any validated decontamination or antimicrobial intervention treatment that is effective in reducing the presence or counts of microbial contaminants at this point in the process? Brisket Opening Questions Yes No Comment Do we clean and sanitize the brisket saw and knife between each carcass, and ensure that we do not puncture the gastrointestinal tract? Do employees maintain proper hygiene practices to prevent the creation of insanitary conditions (e.g., touching the carcass with soiled hands, tools, or garments)? Do we employ any validated decontamination or antimicrobial intervention treatments at this point in the process that are effective in reducing the presence or counts of microbial contaminants?", "55 Rodding the Weasand (Esophagus) Questions Yes No Comment Do we close the esophagus to prevent leakage of rumen contents? Do we maintain proper employee hygiene practices (e.g., wash hands and arms often enough to prevent contamination of the carcass)? Do we change or sanitize the weasand rod between each carcass? Do we properly maintain and clean knives? Do we clean and chill the weasand quickly to limit contamination and pathogen multiplication? Do we employ any validated

decontamination or antimicrobial intervention treatments at this point in the process that are effective in reducing the presence or counts of microbial contaminants? Evisceration Questions Yes No Comment Do we remove visible contamination from the area to be cut (e.g., by trimming, by using air knives, or by steam vacuuming) before the cut is made? Do we remove the uterus in a manner that prevents contamination of the carcass and viscera? Do we properly use knives to prevent damage (i.e., puncturing) to the paunch and intestines? Do we remove contamination in a timely manner and in accordance with accepted reconditioning procedures? Do our employees on moving evisceration lines use footbaths and separate footwear to prevent the footwear from contaminating other parts of the slaughter and dressing operation? Do we employ any validated decontamination or antimicrobial intervention treatments at this point in the process that are effective in reducing the presence or counts of microbial contaminants?", "56 Carcass Splitting Questions Yes No Comment Do we clean and sanitize the saws and knives between each carcass? Do we allow for adequate distance between carcasses (i.e., limit carcass-to-carcass contact)? Do we employ any validated decontamination or antimicrobial intervention treatments at this point in the process that are effective in reducing the presence or counts of microbial contaminants? Do we address the removal of spinal cords in accordance with 9 CFR 310.22? Head and Cheek Meat Processing Questions Yes No Comment Do we properly maintain and clean knives? Do we prevent cross contamination of heads? Do we maintain proper employee hygiene practices to prevent the creation of insanitary conditions (e.g. touching the head with soiled hands, tools, or garments)? Do we quickly chill head and cheek meat to limit pathogen multiplication? Do we employ any validated decontamination or antimicrobial intervention treatments at this point in the process that are effective in reducing the presence or counts of microbial contaminants?", "57 Appendix 2.

Carcass Sanitary Dressing Audit AUDIT LOCATION: Indicate at what point in the slaughter  
process this audit is being performed (check one box). CARCASS #: Indicate the identifying  
number of each carcass included in the audit. CONTAMINATION OBSERVED: Indicate  
\u2018yes\u2019 or \u2018no\u2019 by checking the correct box. CONTAMINATION TYPE:  
Indicate the type of contamination by checking the box by the correct letter. F = Fecal  
contamination I = Ingesta H = Hair GHM = Grease\hook marks, also oil RF = Rail fallout or rail  
dust O = other (such as milk, abscess or any other form of contamination) CONTAMINATION  
LOCATION: Indicate the location of contamination on the carcass by checking the box by the  
correct letter (see diagram below for reference) H = Hock RD = Round RP = Rump SR = Sirloin SL  
= Short Loin R = Rib C = Chuck FS = Foreshank B = Brisket SP = Short Plate F = Flank N = Neck  
DEGREE OF CONTAMINATION: Indicate how much contamination is found on the carcass by  
checking the correct box. Multiple mild or moderate contaminations or one or two severe  
contaminations indicate a significant loss of process control. All slaughter establishments  
should develop process control criteria for each slaughter step and identify criteria for when  
the process is out of control. Establishments should use those criteria to determine the  
effectiveness of their slaughter dressing procedures. The following are examples only.  
Establishments will want to develop their own criteria for each slaughter step to define when  
their process is out of control. - MILD = mild. Contamination is limited to a small area in one  
location on the carcass. For example, a cluster of 3-4 hairs, a speck of fecal contamination, or a  
few small pieces of rail fallout in a small area. - MOD = moderate. Contamination is over one

medium sized area, or is small, but in 3-4 locations on the carcass. For example, multiple clusters of 3-4 hairs over the carcass or one larger cluster of hair. - SEV = severe. Contamination is spread over multiple locations on the carcass, or in one large location. For example, a large streak of fecal contamination, such as may occur from a hide slap. CORRECTIVE ACTION: Indicate \u2018yes\u2019 or \u2018no\u2019 by checking the correct box. CORRECTIVE ACTION TAKEN: Indicate whether the carcass was trimmed or railed out and reworked.

VERIFICATION: Indicate whether the procedures in the slaughter process selected as the audit location effectively prevent contamination by checking \u2018yes\u2019 or \u2018no\u2019 and initial. Establishments should use their process control criteria for determining whether the sanitary dressing procedures at the process step\audit location effectively prevented contamination. COMMENTS: Record further comments, corrective actions (including preventive measures) and recommended actions in the space available.", "59 DIAGRAM TO ASSIST WITH IDENTIFICATION OF CONTAMINATION LOCATION", "60 Appendix 3. Guidance Documents Developed by Industry that include Beef Slaughter and Microbiological Sampling Best Practices Best Practices for Beef Harvest

([https://www.bifsc.org/Media/BIFSCO/Docs/harvest\\_best\\_practice\\_final.pdf](https://www.bifsc.org/Media/BIFSCO/Docs/harvest_best_practice_final.pdf)) This document provides best practices to control microbial contamination throughout the slaughter operation. The implementation of these best practices, with current science and technology, would allow slaughter operators to produce visibly clean carcasses and reduce the incidence level of pathogenic contamination. Best Practices for Spinal Cord Removal

([https://www.bifsc.org/Media/BIFSCO/Docs/spinal\\_cord\\_removal2002.pdf](https://www.bifsc.org/Media/BIFSCO/Docs/spinal_cord_removal2002.pdf)) This document provides Good Manufacturing Practices (GMPs) to improve process control for assuring the removal of spinal cord from vertebral bone. Industry Best Practices for Holding Tested Products

([https://www.bifsc.org/Media/BIFSCO/Docs/holding\\_tested\\_products\\_sept2005.pdf](https://www.bifsc.org/Media/BIFSCO/Docs/holding_tested_products_sept2005.pdf)) This document describes effective best practices to help establishments develop and implement an optimal system for sampling and testing their own products and for holding products when government agencies take a sample. Best Practices for Using Microbiological Sampling

([https://www.bifsc.org/Media/BIFSCO/Docs/microbiological\\_sampling\\_bp\\_march2008.pdf](https://www.bifsc.org/Media/BIFSCO/Docs/microbiological_sampling_bp_march2008.pdf)) This document provides best practices for developing procedures to use microbiological testing to verify process control. Antimicrobial Interventions Reference Document

(<https://www.bifsc.org/Media/BIFSCO/Docs/antimicrobial-interventions-for-beef.pdf>) This document, funded by the beef checkoff, describes the actions that can be taken by industry to reduce the potential for carcass contamination including scientifically proven antimicrobial interventions that can be applied individually or in combination with other treatments to reduce pathogens on carcass surfaces. Sampling, Lotting and Sample Analysis Guidance

([https://www.bifsc.org/Media/BIFSCO/Docs/lotting\\_and\\_sampling\\_of\\_beef\\_products\\_for\\_pathogens\\_analysis\\_update\\_april\\_-2019.pdf](https://www.bifsc.org/Media/BIFSCO/Docs/lotting_and_sampling_of_beef_products_for_pathogens_analysis_update_april_-2019.pdf)) This document provides industry best practices for developing and implementing components (lotting, sampling and laboratory analysis) of a pathogen-testing program as a part of an overall food safety system.", "61

Hazard Analysis Critical Control Point (HACCP) is a systematic and scientific method of process control for the production of safe food products. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to improve the safety of their products. The HACCP models\u2019 focus is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic model for each food processing category defined in the regulation (9 CFR 417.2(b)(1)). The guidebook and the generic models have been revised since their initial publication to be consistent with current science and policy. FSIS recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used \u201cas is\u201d. Establishments are to tailor the model(s) to fit the establishment\u2019s operation. This generic HACCP model illustrates the slaughter processing category. Although this is a beef slaughter model, the model may be used as a starting point for developing a slaughter HACCP plan for other classes of livestock. The slaughter process has inherent food safety hazards that originate with the live animal.

Therefore, the slaughter process has heightened food safety significance. Slaughter establishments typically produce carcasses which are raw intact finished products. The food safety hazards identified for the slaughter process are also common to the Raw Intact and Raw Non-Intact processing categories. The model's critical control points (CCPs) do not necessarily apply to all slaughter operations or products. Products or operations may require fewer or more CCPs depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The food safety critical limits selected must come from scientific documents or other reliable sources. This model includes references for guidance on the selection of critical limits. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis are HACCP records (CFR 417.5(a)). Ensure you maintain the documents produced while developing a HACCP plan. For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage.", "Page 2 of 16 EXAMPLE PRODUCT DESCRIPTION1

Process \ Product Name: Beef Slaughter Process \ Product Name Carcass and carcass parts, tongue, heart, liver, kidney and intestine. Important product characteristics (Aw, pH, Preservatives, etc.) None How it is to be used2 For further processing at this facility or intended for cooking for or by the end consumer Packaging (durability and storage conditions) Product bags and cardboard boxes Shelf Life and at what temperature Not shelf stable \u2013 Keep refrigerated (7 days at \u226440\u00b0F) or frozen (180 days at \u226410\u00b0F) Where it will be sold (specify intended consumers, especially atrisk populations3) Sold direct to household consumers, through retail outlets or distributed to hotels, restaurants, and institutions. Labeling instructions and requirements Product name, inspection legend and establishment number, handling statement, net weight statement, address line, nutritional labeling (when needed) and safe handling instructions. What special distribution controls are required? None DATE: APPROVED BY: 1 Prior to developing the HACCP plan, please read the FSIS Guidebook for the Preparation of HACCP Plans for detailed descriptions of the worksheets and hazard analysis. The FSIS Guidebook for the Preparation of HACCP Plans and the generic HACCP models are intended for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP models are for demonstration purposes only. The models do not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. 2 The intended use or consumer of the product must be identified in accordance with 9 CFR 417.2(a)(2). Identifying the product's intended use in the product description is one way to meet the regulatory requirements specific to 417.2(a)(2). 3 At-risk populations include young children, the elderly and immunocompromised persons.", "Page 3 of 16 EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING MATERIALS Process \ Product Name: Beef Slaughter Meat and meat by-products4 Beef Non-Meat food ingredients None Antimicrobials5 or processing aids Organic Acid6 Packaging material Product bags and cardboard boxes Restricted ingredients or allergens None Other None DATE: APPROVED BY: 4 List all meat (beef), processing aids, and packaging material used in production of these products. This is important to help identify any special ingredients or processes to address in the HACCP plan. 5 FSIS and the Food and Drug Administration (FDA) have a memorandum of understanding (MOU) that establishes the

working relationship followed when responding to notifications for the use of food additives (including ingredients) intended for use in the production of FSIS regulated products. FSIS determines the suitability of the use of food ingredients used in the production of meat, poultry, and egg products. FSIS consults, as necessary, with FDA on the requirements under the Federal Food, Drug & Cosmetic Act and its implementing regulations. See FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat, Poultry and Egg Products for the list of suitable ingredients. 6 There are many different organic acids (for example, lactic acid, acetic acid). If used, establishments will need to select a product best suited for their unique circumstances.", "Page 4 of 16 7 This is an example flow diagram. Establishments\u2019 flow diagrams for the same product may be different. Establishments determine which steps are included in their process. The steps must represent all relevant hazards in the hazard analysis. The Meat and Poultry Hazards and Controls Guide (starting on page 5) describes the usual process steps, potential hazards and frequently used controls for beef slaughter. 8 The Returned Product step (16) is shown as not connected to another process step. Returned product may re-enter the production system at different process steps depending on condition or problem. Returned product may be relabeled, re-processed, discarded, etc. 9 In this model, beef heart undergoes the same CCPs as carcasses because the heart meat may be a component of ground beef. ","EXAMPLE BEEF SLAUGHTER HAZARD ANALYSIS10 Column 1  
Column 2 Column 3 Column 4 Column 5 Column 6 Ingredient\u201c/ Process Step Potential Hazards (introduced or controlled) at this step11 Is the Potential Food Safety Hazard Reasonably Likely to Occur (RLTO)? (Yes or No)12 Justification \u201c Basis for Decision13 If yes in Column 3, (RLTO), What Control Measures Can Be Applied to Prevent, Eliminate, or Reduce the Hazard to Acceptable Levels14 Is this step a Critical Control Point (CCP)? 1a. Cattle Receiving and Holding C: Drug Residues No No cattle purchased from suppliers with history of violative residues (Residue Repeat Violators List). Supplier provides an affirmation. P: Foreign Material No Lack of historical findings from visual inspection during livestock handling and slaughter.15 10 This is an example hazard analysis. Each establishment\u2019s flow chart, hazards analysis, hazards, decision-making, and support may be different. An establishment can determine what \u201csteps\u201d are included in the overall process if all of the hazards are considered in the hazard analysis. The FSIS Meat and Poultry Hazards and Controls Guide (starting on page 5) describes the usual process steps for beef slaughter. 11 Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P). Biological hazards are living organisms. Chemical hazards may be naturally occurring in foods, used or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification. 12 Place the

justification for your decision in column 4. Control measures either go in column 4 for hazards not reasonably likely to occur or go in column 5 for hazards reasonably likely to occur. If a hazard is reasonably likely to occur, then a CCP must be addressed at the step where the hazard is recognized or a later step. See FSIS Meat and Poultry Hazards and Controls Guide for a list of frequently used controls. 13 Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced article must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS document, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan. 14 Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur (NRLTO) because the implementation of a prerequisite program (e.g., Sanitation Standard Operating Procedure (Sanitation SOP), written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation). 15 Note: this \u201chistorical data\u201d must be supported with evidence from the establishment through the establishment\u2019s history or validation data with reference to the actual SOP or prerequisite program. When historical data is not available (for example, a HACCP plan for a new process or product), then system design must be supported by other documentary evidence, such as the FSIS Meat and Poultry Hazards and Controls Guide which states \u201cvisual examination of carcass, parts and viscera\u201d is a frequently used control for foreign material hazards in beef slaughter.", "Step Potential Hazard RLTO Justification \u2014 Basis Controls CCP Page 6 of 16 (needles, wire, buckshot, bullets). Written Sanitary Dressing Procedures to reduce likelihood of cross-contamination. No C: None P: None 6. Carcass Splitting B: Presence of pathogens, STEC and Salmonella. Yes Carcass splitting equipment may transfer contaminants from carcass to carcass. Controlled later at CCP 1 Zero Tolerance Examination, CCP 2 Organic Acid Application and CCP 3 Chilling. Written Sanitary Dressing Procedures to reduce likelihood No", "Step Potential Hazard RLTO Justification √ Basis Controls CCP Page 9 of 16 B: BSE √ SRMs No Written SRM Program to remove, segregate, and dispose of SRMs (9 CFR 310.22) of cross-contamination. Records indicate low likelihood of occurrence. 17 C: None P: None 7. Zero Tolerance Examination (carcass and hearts) CCP 1 B: Presence of pathogens, STEC and Salmonella. Yes FSIS enforces a zero-tolerance standard for visible fecal material, ingesta, or milk on carcasses (Livestock Carcasses and Poultry Carcasses Contaminated With Visible Fecal Material). Hearts are not subject to the FSIS zero-tolerance standard. Hearts are included in this step because they can become a component of raw ground beef products. Therefore, hearts undergo the same CCPs as the carcass. 18 CCP 1 Zero Tolerance Examination for carcasses and hearts. If contamination occurs, it is removed by trimming (9 CFR 310.18(a)). CCP 1 C: None P: None 8. Carcass and Hearts Rinse B: Presence of pathogens, STEC and Salmonella. Yes Rinse with potable water to remove blood, bone dust, and debris. Controlled later at CCP 2 Organic Acid Application and CCP 3 Chilling. No C: None P: None 17 When historical data is not available (for example, a HACCP plan for a new process or product), then system design must

be supported by other documentary evidence, such as the FSIS Meat and Poultry Hazards and Controls Guide which states \u201cmimimize cross-contamination through sanitary dressing procedures; Sanitation SOPs\u201d is a frequently used control for biological hazards in beef slaughter.<sup>18</sup> This generic beef slaughter HACCP model demonstrates how beef heart meat\u2014which is to be incorporated into ground beef\u2014can be addressed in the hazard analysis. In this model, hearts are subject to the CCP 1 Zero Tolerance Examination, although beef hearts are not subject to FSIS\u2019 zero tolerance policy. Beef hearts are subject to the requirements of 9 CFR 310.18(a).", "Step Potential Hazard RLTO Justification \u2225 Basis Controls CCP Page 10 of 16 9. Harvest Tongue, Liver, Kidney and Intestine B: Presence of pathogens, STEC and Salmonella. B: Outgrowth of pathogens, STEC and Salmonella. B: BSE \u2225 SRMs No Yes No The intestinal tract, mouth, hide, and hooves of cattle may harbor these pathogens. The STEC and Salmonella biological hazards for tongue, liver, kidney and intestine are recognized as not reasonably likely to occur because these products are not to be incorporated into raw ground beef products. Chilling inhibits growth of pathogens. (Tompkin, R.B. 1996). Outgrowth of STEC and Salmonella is reasonably likely to occur, and outgrowth is controlled with product chilling (CCP 3) and cold storage. Written SRM Program to remove, segregate and dispose of SRMs (9 CFR 310.22). Written Sanitary Dressing Procedures designed to reduce the likelihood of crosscontamination. Controlled later at CCP 3 Chilling. No C: None P: None 9a. Harvest Hearts B: Presence of pathogens, STEC and Salmonella. Yes Hearts may become contaminated during evisceration. The STEC and Salmonella biological hazards for beef hearts are recognized as reasonably likely to occur because heart meat is to be incorporated into raw ground beef product. Controlled later at CCP 1 Zero Tolerance Examination, CCP 2 Organic Acid Application and CCP 3 Chilling. Written Sanitary Dressing Procedures designed to prevent the likelihood of crosscontamination. No C: None P: None 10. Package Tongue, Liver, B: Outgrowth of pathogens, Yes Low product temperatures inhibit growth of pathogens. (Tompkin, R.B. 1996) Controlled with CCP 3 Chilling. No", "Step Potential Hazard RLTO Justification \u2225 Basis Controls CCP Page 11 of 16 Kidney, and Intestine STEC and Salmonella. C: None P: None 11. Organic Acid Application B. Presence of pathogens, STEC and Salmonella. Yes Eliminate or reduce STEC to non-detectable levels. Eliminate or reduce Salmonella. CCP 2 Organic Acid Application.<sup>19, 20</sup> CCP 2 C: Incorrect acid concentration. No We adhere to the manufacturer\u2019s guidance on storing, mixing, verifying concentrations, and applying the organic acid. The acid is used in accordance with FSIS Directive 7120.1.21 P: None 12. Chilling B: Outgrowth of pathogens, STEC and Salmonella. Yes Chilling inhibits growth of pathogens. FSIS Compliance Guideline for Minimizing the Risk of Shiga Toxin-Producing Escherichia Coli (STEC) and Salmonella in Beef (including Veal) Slaughter Operations CCP 3 Chilling Process Control SOP (prerequisite program) for sampling of microbial organisms to monitor the establishment\u2019s ability to maintain process control (9 CFR 310.18). CCP 3 19 If an establishment implements a process consistent with the process specifications described in the scientific support, and the scientific support contains microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, the in-plant validation data collected during the 90 day initial validation period will consist of data on quantifiable characteristics of the critical operational parameters, such as pressure, temperature, and concentration (FSIS Compliance Guideline HACCP Systems Validation, page 27).<sup>20</sup> The Pennsylvania State University worked with Texas Tech University and Washington

State University to generate new data that very small establishments can use to effectively remove pathogens from carcass surfaces. See the Antimicrobial Spray Treatments for Red Meat Carcasses Processed in Very Small Meat Establishments for additional information. 21 FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat, Poultry and Egg Products contains the list of substances that may be used in the production of meat and poultry products. The list contains the allowable amounts and the intended use of the approved antimicrobials. The list (Directive 7120.1) can be used as supporting documentation for chemical hazard controls (safety and suitability). Directive 7120.1 cannot be used as support for the control of biological hazards because the antimicrobial concentration needed to control bacteria is different from the concentrations required for safety and suitability. ", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 12 of 16 C: None P: None 13. Cold Storage B: Outgrowth of pathogens, STEC and Salmonella. States Department of Agriculture (USDA) published the Pathogen Reduction\Hazard Analysis Critical Control Point (HACCP) Systems Final Rule in July 1996. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to address safety hazards reasonably likely to occur in their production process. Therefore, this HACCP model\u2019s focus, and the focus of the other HACCP models, is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic model for each food processing category defined in regulation 9 CFR 417.2(b)(1). The guidebook and the generic models have been updated since their initial publication to be consistent with current science and policy. FSIS recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used \u201cas is.\u201d FSIS recommends that establishments tailor the model(s) to fit the establishment\u2019s operations. Thermally processed, commercially sterile (TPCS) products are commonly referred to as canned products although the containers can be metal cans, glass jars, flexible pouches, paperboard, and other types of hermetically sealed containers. Processors of TPCS products must identify their biological, physical, and chemical food safety hazards when performing their hazard analysis. Under 9 CFR 417.2(b)(3) of the HACCP regulations, establishments do not have to address the microbiological food safety hazards identified in its hazard analysis if the product is produced in accordance with the requirements of 9 CFR Part 431. However, canning establishments that identify chemical or physical food safety hazards as reasonably likely to occur (RLTO) are to address those hazards in their HACCP plan. The regulations provide that canning establishments do not have to address microbiological hazards in their HACCP plan because FSIS recognized that the canning regulations were based on HACCP concepts and provide for the analysis of thermal processing systems and controls to exclude biological food safety hazards. However, a canning establishment may choose to address the microbiological food safety hazards in its HACCP plan. In either case, the requirements in 9 CFR parts 431 and 417 must be met through the establishment\u2019s HACCP system. This HACCP model illustrates the scenario when the establishment does not address microbiological hazards in a HACCP plan and does not identify chemical or physical food safety hazards as reasonably likely to occur. Thus, this model does not include any critical control points (CCP). This model does contain the required product description, list of product ingredients and materials, flowchart, and hazard analysis. The model may not necessarily apply to all operations or products.

Products or operations may require CCPs depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis, are HACCP records (9 CFR 417.5(a)). Ensure you maintain the documents produced while developing a HACCP plan. For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage.", "Page 2 of 15 EXAMPLE PRODUCT DESCRIPTION1 Thermally Processed, Commercially Sterile: Beef Stew Process or

Product name Beef Stew Important product characteristics (Aw, pH, Preservatives, etc.) None Intended use<sup>2</sup> Ready-to-eat; typically heated before consumption. Packaging (durability and storage conditions) 3-piece metal, double seamed (\u201cSanitary\u201d) can. Shelf life and at what temperature<sup>3</sup> 3 years under cool (e.g., 75 \u00b0F or lower) and dry conditions; Protected from freezing. Where it will be sold (specify intended consumers, especially atrisk populations)<sup>4</sup> Sold to household consumers through retail outlets or distributed to hotels, restaurants, and institutions (HRI). Labeling instructions and requirements Product name, inspection legend and establishment number, heating instructions, net weight statement, address line, nutrition facts, and ingredients list. Special distribution control None DATE: APPROVED BY: 1 Prior to developing the HACCP plan please read the Guidebook for the Preparation of HACCP Plans for detailed descriptions of the worksheets and hazard analysis. The FSIS Guidebook for the Preparation of HACCP Plans and the generic HACCP models are intended for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP model is for demonstration purposes only. The model does not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. 2 The intended use or consumer of the product must be identified in accordance with 9 CFR 417.2(a)(2). Identifying the product\u2019s intended use in the product description is one way to meet the regulatory requirements specific to 417.2(a)(2). 3 Each establishment\u2019s products may have their own defined shelf life. Thermally Processed, Commercially Sterile products must be shelf stable per 9 CFR 431.1. 4 At-risk populations include young children, the elderly, and immunocompromised persons." , "Page 3 of 15 EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING MATERIALS<sup>5</sup> Thermally Processed, Commercially Sterile: Beef Stew Meat and meat by-products Frozen beef Non-meat food ingredients Water, Frozen diced celery, Frozen sliced carrots, Frozen tomato puree, Modified food starch, Textured soy protein, Spice mix, Salt, Sugar. Antimicrobial interventions<sup>6</sup> and processing aids None Packaging material<sup>7</sup> 3-piece double seamed (\u201cSanitary\u201d) cans with capacities of 7 oz, 11.5 oz, 12 oz and 20 oz. Restricted ingredients or Allergens Texturized soy protein Other None DATE: APPROVED BY: 5 List all meat, non-meat ingredients, restricted ingredients (for example, nitrites), processing aids, and packaging material used in production of this product. This is important to help identify any special ingredients or processes to address in the HACCP plan. See the FSIS Compliance Guideline Allergens and Ingredients of Public Health Concern: Identification, Prevention and Control, and Declaration through Labeling for detailed information on allergens. 6 FSIS and the Food and Drug Administration (FDA) have a memorandum of understanding (MOU) that establishes the working relationship followed when responding to notifications for the use of food additives (including ingredients) intended for use in the production of FSIS regulated products. FSIS determines the suitability of the use of food ingredients used in the production of meat, poultry, and egg products. FSIS consults, as necessary, with FDA on the requirements under the Federal Food, Drug & Cosmetic Act and its implementing regulations. See FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat Poultry and Egg Products for the list of suitable ingredients. 7 Establishments will follow different process schedules developed by a processing authority for the product packaged in different container sizes." , "Page 4 of 15 EXAMPLE PROCESS FLOW DIAGRAM<sup>8</sup> Thermally Processed, Commercially Sterile: Beef Stew 18. 10 Is the Hazard Reasonably Likely to occur (RLTO)?  
11 Justification or Basis for Decision  
i If yes in Column 2 (hazard RLTO), What Control Measures Can Be Applied to Prevent, Eliminate, or Reduce the Hazard to Acceptable Levels  
ii Is this Step a Critical Control Point (CCP)?  
10 Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P). Biological hazards are living organisms. Chemical hazards may be naturally occurring in foods, used or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification.  
11 Place the justification for your decision in column 3. Control measures for hazards not reasonably likely to occur are entered in column 3. Control measures for hazards reasonably likely to occur are entered in column 4. If a hazard is reasonable likely to occur, then a CCP must be addressed at this step or a later step. See FSIS Meat and Poultry Hazards and Controls Guide for a list of frequently used controls.

1. Receiving and Storage of Frozen Beef  
B: Presence and outgrowth of pathogens, Shiga-toxin producing Escherichia coli (STEC) (E. coli O157:H7, O26, O45, O103, O111, O121 and O145), Salmonella and Clostridium botulinum  
No Beef may be contaminated with Shiga-toxin producing Escherichia coli (STEC) (E. coli O157:H7, O26, O45, O103, O111, O121 and O145), Salmonella and Clostridium botulinum.  
9 CFR 417.2(b)(3) exempts establishment from having to address microbiological food safety hazards in the HACCP plan if the product is produced in accordance with the requirements in 9 CFR Part 431. Written receiving program to ensure product specifications, temperature, and package integrity. Written Sanitation Standard Operating Procedure (SOP), including temperature control and maintenance of sanitary conditions. The product is thermally processed during the thermal process step in accordance with 9 CFR Part 431.", "Potential Hazard RLTO Justification or Basis Controls CCP Page 6 of 15  
12 This Foreign Material SOP (prerequisite program) should have details on how this procedure (such as metal prevention controls) is preventing the hazard from occurring as well as the on-going verification procedures. These controls should be evident within the written document upon review. The Foreign Material SOP and plant data related to on-going verification activities then become part of recordkeeping and historical data.  
BSE (Prions)  
No Bovine Spongiform Encephalopathy (BSE)  
Prions associated with specified risk materials (SRM) is a potential hazard in beef products. Only boneless beef received from approved suppliers according to company purchasing program. SRMs are required to be removed by supplier prior to release into commerce. Letters of Guarantee (LOGs) from suppliers describing SRM controls.

C: Antibiotic

and pesticide residues No Letters of Guarantee (LOG) from suppliers describing quality controls and prevention procedures. The blanket LOG is updated annually. Approved supplier program and ongoing communication with suppliers to verify LOGs. P: Foreign materials, i.e., metal, rubber, plastic, and wood. No Visual examination procedures in the Foreign Material SOP.12 Establishment Foreign Material SOP records demonstrate no incidents of foreign materials detected in products received. 2. Non-meat Ingredients Receiving and Storage B: Presence and outgrowth of pathogens, e.g., STEC, Salmonella and Clostridium botulinum No 9 CFR 417.2(b)(3) exempts establishment from having to address microbiological food safety hazards in the HACCP plan if the product is produced in accordance with the requirements in 9 CFR 431. Written receiving program to ensure product specifications, temperatures, and package integrity. Purchasing program to ensure microbiological specifications for non-meat ingredients are met. Written Sanitation SOP including storage temperature control and", "Potential Hazard RLTO Justification or Basis Controls CCP Page 7 of 15 13 Note: this \u201chistorical data\u201d must be supported with evidence from the establishment through the establishment\u2019s history or validation data with reference to the actual SOP or prerequisite program. When historical data is not available (for example, a HACCP plan for a new process or product), then system design must be supported by other documentary evidence, such as the FSIS Meat and Poultry Hazards and Controls Guide which states \u201cletters of guarantee, certificate of analysis, approved supplier program and proper storage to prevent contamination of allergen-free products\u201d as frequently used controls for the receiving and storage of pesticides and allergens. maintenance of sanitary conditions. C: Pesticide residues and undeclared allergens No Written receiving program to ensure product specifications. Allergen Control SOP ensures ingredient statements on finished product labels match ingredient formulation. P: None 17. Storage and Shipping B: None C: None P: None 18. Returned Product B: None Reinspection SOP implemented before accepting returned product. Person(s) or business returning the product must demonstrate the product was held in the appropriate temperature range and in a sanitary manner. When such assurance is not available, returned product is rejected or destroyed. Opened packages are not accepted. Accepted product enters", "Potential Hazard RLTO Justification or Basis Controls CCP Page 15 of 15 the appropriate step of the production system based on findings of product evaluation. Notify FSIS personnel when returned product has been accepted. C: None P: None

DATE: APPROVED BY: i Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced articles must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS program, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan. ii Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, or antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page

7", "3 Preface This is a revised version of the FSIS Guideline on Kit Product Labeling. FSIS updated it in response to comments received on the previous version posted on June 9, 2019. The Agency revised the guideline to announce that FSIS no longer will provide mandatory inspection services for the assembly of kits as described in this guideline, and that such kits are eligible for FSIS voluntary inspection; clarify that it does not apply to products produced under the retail exemption; clarify that kits labeled as a standardized product must meet the regulatory standard; and clarify that uninspected kits placed into shipping containers must not bear the USDA legend on the shipping container. The guideline also includes changes to improve its readability. \u2022 This guideline represents FSIS\u2019 current thinking on these topics and should be considered usable as of its issuance. Establishments that used previous versions of the FSIS Guideline on Kit Product Labeling as food safety system support (9 CFR 417.5(a)(1) and 9 CFR 417.4(a)(1)) should update their procedures based on this guideline as necessary. The information in this guideline is provided to assist meat and poultry establishments in meeting the regulatory requirements. The contents of this document do not have the force and effect of law and are not meant to bind the public in any way. This document is intended only to provide clarity to industry regarding existing requirements under the regulations. This guideline is focused on small and very small establishments in support of the Small Business Administration\u2019s initiative to provide small businesses with assistance under the Small Business Regulatory Enforcement Fairness Act (SBREFA). However, all meat and poultry establishments may apply the recommendations in this guideline. Although large plants can benefit from the information, focusing the guideline on the needs of small and very small establishments provides them with assistance that may be otherwise unavailable to them.

Congressional Review Act Pursuant to the Congressional Review Act at 5 U.S.C. 801 et seq., the Office of Information and Regulatory Affairs has determined that this guideline is not a \u201cmajor rule,\u201d as defined by 5 U.S.C. 804(2).

Purpose This guideline contains information to assist meat and poultry establishments comply with the inspection and labeling requirements of the Federal Meat Inspection Act (FMIA), Poultry Products Inspection Act (PPIA), and the labeling requirements in 9 CFR part 317 and 9 CFR 381 subpart N for wholesale multi-component food kits (henceforth, kit products) that contain an inspected and labeled meat or poultry component. This guideline includes information on:

"4 \u2022 The definition of \u201ckits\u201d in the context of this guideline;

\u2022 Types of kits that may be assembled without inspection; and

\u2022 Labeling requirements for kits assembled without FSIS inspection.

Reason for Issuing the Guideline FSIS has received numerous inquiries on how kit products should be labeled to ensure compliance with FSIS regulations and policies, and whether certain kit products may be assembled without FSIS inspection. In the past, FSIS has not considered kit products that did not reference meat or poultry in the product name, such as \u201cStir Fry\u201d or \u201cSkillet Meal,\u201d as products of the meat or poultry industry because the product name often makes no reference to meat or poultry. However, manufacturers have increasingly wanted to highlight the meat or poultry component in the coined name, e.g., \u201cChicken Skillet Meal\u201d or \u201cGourmet Beef Dinner.\u201d Historically, the Agency has required kit products purporting to be meat or poultry products to be assembled under FSIS inspection. After further evaluation, the Agency has determined that the act of assembling a kit product whose label makes reference to meat or poultry in its name does not need to be done under FSIS inspection, as long as certain conditions are met. Changes

from the Previous Version of the Guideline This guideline is final. FSIS will update this guideline, as necessary, should new information become available. FSIS made the following changes to this guideline to address the comments received on the previous version during the comment period and to include additional scientific information. This version incorporates the following changes: \u2022 Announce that FSIS no longer will provide mandatory inspection services for the assembly of kits as described in this guideline, and that such kits are eligible for FSIS voluntary inspection under 9 CFR 350.3(c); \u2022 Clarify that the guideline does not apply to products produced under the retail exemption; \u2022 Clarify that a kit named as an FSIS standardized product must meet the standard when prepared; and \u2022 Clarify that when an official establishment places a kit assembled without FSIS inspection into a container for shipping, the establishment may not apply the USDA inspection legend to the outer container.

How to Effectively Use the Guideline", "5 This guideline is organized to provide users with current recommendations. To use this guideline, FSIS recommends that readers use the navigation headings to move efficiently through the document sections of interest. Hyperlinks, where provided, will quickly take you to the correct place in the document electronically and are also provided to other complementary documents.

Questions Regarding Topics in this Guideline If after reading this guideline you still have questions, FSIS recommends searching the publicly posted Knowledge Articles (\u201cPublic Q&As\u201d) in the askFSIS database. If after searching the database, you still have questions, refer them to the Office of Policy and Program Development through askFSIS and select Labeling as the Inquiry Type or by telephone at 1-800-233-3935. Documenting these questions helps FSIS improve and refine present and future versions of the guideline and associated issuances.", "6 FSIS Guideline on Kit Product Labeling

Background This guideline is for official establishments under FSIS inspection and establishments under the Food and Drug Administration\u2019s jurisdiction that plan to assemble kit products that contain an already inspected and labeled meat or poultry component in a common container or packaging marketed as a single unit. This guidance does not apply to instances in which the meat or poultry component is processed (e.g., sliced), or portioned and packaged by the facility assembling the kit, if the kit will be sold for resale, because such activities require FSIS inspection.

Kit Products In the context of this guideline, a kit product consists of individually-packaged meat or poultry products and other food components sold together as a single unit. Examples of kit products include: \u2022 A \u201cSpaghetti Dinner Kit\u201d which includes a bag of fully-cooked meatballs, a jar of marinara sauce, and uncooked spaghetti; \u2022 A \u201cChicken Fiesta Kit\u201d which includes a packet of raw, marinated chicken breast strips, flour tortillas, a can of refried beans, and a package of rice; and \u2022 A \u201cNugget Lunch Kit\u201d which includes a bag of fully-cooked nugget-shaped chicken patties, a container of cole slaw, a slice of corn bread, and a juice box. There are many varieties of kit products, including but not limited to: wraps, pizza, stew, salads, fajitas, stroganoff, or stir fry skillet meals, that include meat or poultry components. Kit products may be marketed to provide one meal to multiple consumers, such as a \u201cBeef Stew Kit\u201d with multiple servings, or a kit product could be a single serving meal for one, such as an \u201cIndividual Pizza Lunch Kit\u201d with pizza components, a brownie, and a soda. The meat or poultry items are commonly sold as fully-cooked; however, some of these items may require cooking.

Assembly Without Inspection The Agency has determined that the act of assembling a kit product whose label makes reference to meat or poultry in its name does not

need to be done under FSIS inspection, as long as the following conditions are met: 1. The meat\poultry component is prepared and separately packaged under FSIS inspection and labeled with all required features, including: \u2022 Product name, \u2022 Handling statement (e.g., Keep Refrigerated), if product is perishable, \u2022 USDA legend and establishment number of the official establishment that packaged and labeled the meat\poultry component,"7 \u2022 Name and address of the manufacturer, packer, or distributor, \u2022 Ingredients statement (if composed of more than one ingredient), and \u2022 Safe handling instructions if the meat or poultry component is not ready-to-eat; 2. The outer label for the kit product identifies all the individual components in the kit; and 3. The outer kit label clearly identifies the product as a single unit or \u201ckit,\u201d such as \u201cChicken Barbecue Dinner Kit\u201d or \u201cBeef Lasagna Meal.\u201d Although the word \u201ckit\u201d is not required on the label, all labeling must clearly indicate that the product consists of individual components. If assembly of kit products occurs at an official establishment, the assembly would be performed without FSIS inspection and may be done outside the official hours of inspection. Thus, official establishments would not incur any charges for FSIS inspection or for overtime. The assembly of kit products meeting the above conditions remains eligible for FSIS voluntary inspection as a food inspection service under 9 CFR 350.3(c). Going forward, FSIS will no longer provide mandatory inspection services for the assembly of such kits. FSIS has determined that providing inspection for these products as a voluntary food inspection service is the best use of Agency resources. Note: The guideline does not apply to boxes of ingredients (including FSIS-inspected, fully labeled meat and poultry products) that are shipped directly to consumers to help them prepare home-cooked meals. These boxes\kits are typically prepared and packed without FSIS inspection under the retail exemption (see 9 CFR 303.1(d) and 381.10(d)). The retail exemption from FSIS inspection is unchanged by this document.

**Labeling** Although FSIS will no longer conduct mandatory inspection of the assembly of the kit product, the meat or poultry component of the kit remains under FSIS\u2019 jurisdiction and, as such, is required to meet all applicable FSIS labeling requirements, including product standards described in 9 CFR 319 and 381 Subpart P. Labels for such kit products assembled without FSIS inspection are not required to be submitted to FSIS for approval. Kit products assembled without FSIS inspection will not bear the USDA mark of inspection on the label of the common packaging containing the components of the kit. The mark of inspection, instead, would be on the label and packaging of the meat or poultry component included in the kit. When kits that were not assembled under FSIS inspection and therefore, do not bear the USDA legend, are placed into a larger container for shipping, the outer shipping container may not bear the USDA legend."8 https://www.fsis.usda.gov/contact-us/askfsis USDA FSIS www.fsis.usda.gov 2021"]},{"file\_name":"FSIS\_GD\_2021\_0012","title":"HACCP Model for Raw, Non-Intact Turkey","num":"FSIS-GD-2021-0012","id":"96ac125f13b39909548bc44b905c9990c09f8a2ac6c75fe35dbc8b7cc73f1ce4","corp\_us":"fsis\_guidelines","source\_page\_url":"https://www.fsis.usda.gov/policy/fsis-guidelines","url":"https://www.fsis.usda.gov/sites/default/files/media\_file/2021-10/FSIS-GD-2021-0012.pdf","type":"pdf","n\_pages":12,"word\_count":3768,"text\_by\_page":["HACCP Model for Raw, Non-Intact Turkey The United States Department of Agriculture (USDA) published the Pathogen Reduction\Hazard Analysis Critical Control Point (HACCP) Systems Final Rule in July

1996 mandating all USDA inspected meat and poultry establishments implement a HACCP system. Hazard Analysis Critical Control Point (HACCP) is a systematic and scientific method of process control for the production of safe food products. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to improve the safety of their products. The HACCP models\u2019 focus is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic model for each food processing category defined in regulation (9 CFR 417.2(b)(1)). The guidebook and the generic models have been revised since their initial publication to be consistent with current science and policy. FSIS recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used \u201cas is\u201d. Establishments are to tailor the model(s) to fit the establishment\u2019s operation. This Raw, Non-Intact model uses a ground turkey product to demonstrate hazard analysis and HACCP plan principles. The model may serve as a starting point for any ground poultry product. The model\u2019s critical control points (CCPs) do not necessarily apply to all operations or products. Products or operations may require fewer or more CCPs depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The food safety critical limits selected must come from scientific documents or other reliable sources. This model includes references for guidance on the selection of critical limits. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis are HACCP records (CFR 417.5(a)). The selection of processing categories and HACCP models are preliminary steps to completing a hazard analysis. The documents produced during the selection process are HACCP records. Ensure you maintain the documents produced while developing a HACCP plan. For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage.<sup>1</sup> This information is best suited for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP model is for demonstration purposes only. The model does not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products.","Page 2 of 12 EXAMPLE PRODUCT DESCRIPTION2 Process Type and Product Name: Raw, Non-Intact Turkey Product Name Fresh or Frozen Ground Turkey (Raw, Non-Intact) Important product characteristics (Aw, pH, Preservatives, etc.) None How it is to be used For further processing at this facility or another establishment or intended for cooking for or by end consumer3 Packaging (durability and storage conditions) Tray packs (Case ready) Shelf life and at what temperature<sup>4</sup> 7 Days at <40\u00baF; 180 days at < 0\u00baF Where it will be sold (Specify intended consumers, especially at-risk populations)<sup>5</sup> Sold direct to another establishment or to household consumers through retail outlets or distributed to hotels, restaurants, and institutions (HRI). Labeling instructions Product name, keep refrigerated or frozen, safe handling instructions, nutrition facts, establishment number, and cooking

instructions Special distribution control Keep refrigerated or frozen DATE: APPROVED BY: 2 Prior to developing the HACCP plan please read the FSIS Guidebook for the Preparation of HACCP Plans for detailed descriptions of the worksheets and hazard analysis. The FSIS Guidebook for the Preparation of HACCP Plans and the generic HACCP models are intended for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP models are for demonstration purposes only. The models do not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. 3 The intended use or consumer of the product must be identified in accordance with 9 CFR 417.2(a)(2). Identifying the product's intended use in the product description is one way to meet the regulatory requirements specific to 417.2(a)(2). 4 Each establishment's products may have their own defined product shelf life. 5 At-risk populations include young children, the elderly, and immunocompromised persons.", "Page 3 of 12 EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING MATERIAL6 Process Type and Product Name: Raw, Non-Intact Turkey Meat and Meat by-products Turkey trim (dark and light meat, skin on and skin off) from outside source purchase and in-house slaughter operations Non-meat food ingredients None Antimicrobial interventions and processing aids7 Antimicrobial Acid8 Packaging materials Tray packaging, retail plastic packaging and rollstock plastic, self-adhesive labels Restricted ingredients and allergens None Other None DATE: APPROVED BY: 6 List all meat, non-meat ingredients, restricted ingredients (for example, nitrites), processing aids, and packaging material used in production of this product. This is important to help identify any special ingredients or processes to address in the HACCP plan. See the FSIS Compliance Guideline Allergens and Ingredients of Public Health Concern: Identification, Prevention and Control, and Declaration through Labeling for detailed information on allergens. To review restrictions on the use of nitrite and sodium ascorbate or sodium erythorbate, see 9 CFR 424.22(b). 7 FSIS and the Food and Drug Administration (FDA) have a memorandum of understanding (MOU) that establishes the working relationship followed when responding to notifications for the use of food additives (including ingredients) intended for use in the production of FSIS regulated products. FSIS determines the suitability of the use of food ingredients used in the production of meat, poultry, and egg products. FSIS consults, as necessary, with FDA on the requirements under the Federal Food, Drug & Cosmetic Act and its implementing regulations. See FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat, Poultry and Egg Products for the list of suitable ingredients. 8 Antimicrobial interventions even if considered processing aids must be addressed in the HACCP system. See the FSIS Compliance Guideline HACCP Systems Validation April 2015 (page 5).", "Page 4 of 12 EXAMPLE PROCESS FLOW DIAGRAM9 Process Type and Product Name: Raw, Non-Intact Turkey10 9. Returned Product11 DATE: APPROVED BY: 9 This is an example flow diagram. Establishments' flow diagrams for the same product may be different. Establishments determine which steps are included in their process. The steps must represent all relevant hazards in the hazard analysis. 10 If receiving both in-house and outside (purchased) trim, product flow and lots should be separated for traceability reasons. When inhouse and purchased trim is combined, maintain a record of the finished product source material(s). 11 The Returned Product step (9) is shown connected to step 8 Storage and Distribution. Returned product may re-enter the production system at different process steps depending on condition

or problem. Returned product may be relabeled, re-ground, discarded, tempered, etc. 1a. Receiving of Turkey Components from Outside Source and In-house Slaughter 2. Cooler Storage 7. Packaging and Labeling CCP 2 8. Storage and Distribution 4. Grinding (trim) 5. Metal Detection 3. Antimicrobial Application for Turkey Components CCP 1 1b. Receiving and Storage of Packaging Material and Antimicrobial Products 6. Rework", "EXAMPLE HAZARD ANALYSIS 12 Raw, Non-Intact Turkey 12 See the FSIS Guideline for Controlling Campylobacter in Raw Poultry, and the FSIS Guideline For Controlling Salmonella in Raw Poultry for best practices and a list of scientific and technical references. 13 Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P). Biological hazards are living organisms. Chemical hazards may be naturally occurring in foods, used or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification. 14 Place the justification for your decision in column 4. Control measures for hazards not reasonably likely to occur are entered in column 4. Control measures for hazards reasonably likely to occur are entered in column 5. If a hazard is reasonably likely to occur, then a CCP must be addressed at this step or a later step. See FSIS Meat and Poultry Hazards and Controls Guide for a list of frequently used controls. 15 Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced article must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from FSIS, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan. 16 Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation standard operating procedures (Sanitation SOP), written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, or antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5). 17 To determine a CCP, see FSIS Guidebook for the Development of HACCP Plans for decision tree to evaluate the areas of control (column 5) to determine the best CCP to control, reduce, or eliminate a hazard. Column 1 Column 2 Column 3 Column 4 Column 5 Column 6 Ingredient \ Process Step Potential Hazards (introduced or controlled) at this Step 13 Is the Potential Food Safety Hazard Reasonably Likely to Occur (RLTO)? (Yes or No) 14 Justification \ Basis for Decision in Column 3 15 If yes in Column 3 (hazard RLTO), What Control Measures Can Be Applied to Prevent,

Eliminate, or Reduce the Hazard to Acceptable Levels<sup>16</sup> Is this Step a Critical Control Point (CCP)?<sup>17</sup> 1a. Receiving of Turkey Components from Outside Source and In-house Slaughter B: Outgrowth of Pathogens: Salmonella, Campylobacter No Turkey components received from establishments with validated HACCP systems or from the establishment's slaughter process include antimicrobial applications and other measures to reduce biological hazards to acceptable levels. Written Turkey Receiving Standard Operating Procedure (SOP) to establish product specifications at receiving to prevent the introduction of hazards at the receiving step. Letter of Guarantee (LOG) is on file for each supplier of turkey", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 6 of 12 18 This Foreign Material SOP (prerequisite program) should have details on how this procedure is preventing the hazard from occurring (metal prevention controls) as well as the ongoing verification procedures. These controls should be evident within the written document upon review. The Foreign Material SOP and plant data related to on-going verification activities then become part of recordkeeping and historical data. product. Prerequisite program at product receiving to monitor incoming product temperatures and packaging or container conditions to prevent pathogen outgrowth and product contamination. C: None P: Foreign Material No Written Foreign Material SOP<sup>18</sup> for visual inspection of product containers at receiving. 1b. Receiving and Storage of Packaging Material and Antimicrobial Products B: None C: Non-food grade packaging material and Antimicrobials No Letter of Guarantee (LOG) for packaging materials and antimicrobials. Written Chemical Receiving, Storage, and Use SOP for management of antimicrobials. P: Foreign material No Receiving Letters of Guarantee (LOG) from suppliers for foreign material specifications. Written Foreign Material SOP for visual inspection of product containers at receiving. Written Storage SOP for packaging materials and antimicrobials.", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 7 of 12 2. Cooler Storage B: Pathogen outgrowth (Salmonella, Campylobacter) No Pathogen outgrowth may result if temperatures are not maintained at levels to prevent bacterial multiplication. Product is placed in storage coolers or freezers to prevent product temperatures that promote pathogen outgrowth (Tompkin, R.B. 1996).<sup>19</sup> Written Sanitation and Temperature Control SOP for condition of use and maintaining cooler temperatures to prevent outgrowth of microorganisms. C: None P: None 3. Antimicrobial Application for Turkey Components B: Outgrowth of Pathogens (Salmonella, Campylobacter) Yes Well documented that raw poultry may carry pathogens. Antimicrobial dips are documented to reduce pathogenic contamination to acceptable levels on meat. Antimicrobial dips and their scientifically validated critical operational parameters are used to reduce pathogens.<sup>20</sup> Yes CCP 1 C: Inappropriate concentration of antimicrobial dips No Written Chemical Receiving, Storage, and Use SOP for mixing and determining concentration of chemicals to ensure the mixture is made per the manufacturer's instructions and is within the allowable limits identified in Directive 7120.1 (Food Contact Notification (FCN) number).<sup>21</sup> 19 The Significance of time-temperature to growth of foodborne pathogens during refrigeration at 40-50°F (Tompkin, R.B. 1996) 20 If an establishment implements a process consistent with the process specifications described in the scientific support, and the scientific support contains microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, the in-plant validation data collected during the 90 day initial validation period will consist of data on quantifiable characteristics of the critical operational parameters, such as pressure,

temperature, and concentration. However, if an establishment implements different critical operational parameters in the process from the scientific support, or the scientific support identified does not contain microbiological data, then the establishment should collect in-plant data demonstrating the critical operational parameters that it has implemented can all be met AND should collect in-plant microbiological validation data or identify scientific support with microbiological data that demonstrates the effectiveness of those implemented critical operational parameters (FSIS Compliance Guideline HACCP Systems Validation, page 27). 21 Provide reference for scientific support and validation for effective concentrations and support for critical operational parameters that reduce biological hazards. FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat, Poultry and Egg Products contains the list of substances that may be used in the production of meat and poultry products. The list contains the allowable amounts and the intended use of the approved antimicrobials. The list (Directive 7120.1) can be used as supporting documentation for chemical hazard controls (safety and suitability). Directive 7120.1 cannot be used as support for the control of biological hazards because the antimicrobial concentration needed to control bacteria is different from the concentrations required for safety and suitability.", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 8 of 12 P: None 4. Grinding (trim) B: Pathogen outgrowth (Salmonella, Campylobacter) Yes Pathogen outgrowth may occur during processing procedures due to processing room temperatures, product handling and grinding equipment. The hazard is controlled later at CCP 2 Packaging and Labeling. Written Sanitation program for grinding operation. Temperature Control During Grinding SOP to prevent pathogen outgrowth during production. No C: None P: Metal contamination and Bone fragments No Written Equipment Examination and Preventive Maintenance on Grinder SOP22 to prevent metal contamination from equipment. Written Preventive Maintenance of Bone Separator on Grinder SOP to establish controls for bone contamination prevention. 5. Metal Detection B: None C: None P: Metal contamination No Written Metal Detection SOP for products. Metal Detection SOP records supporting historical data for low likelihood of occurrence due to routine maintenance of grinding equipment.23 22 This Written Equipment Examination and Preventive Maintenance on Grinder SOP (prerequisite program) should have details on how this procedure is preventing the hazard from occurring (such as metal prevention controls) as well as the on-going verification procedures. These controls should be evident within the written document upon review. The Grinder SOP and plant data related to on-going verification activities then become part of recordkeeping and historical data. 23 Note: this \u201chistorical data\u201d must be supported with evidence from the establishment through the establishment\u2019s history or validation data with reference to the actual SOP (which is a prerequisite program). When historical data is not available (for example, a HACCP plan for a new process or product), then system design must be supported by other documentary evidence. Documentary evidence such as the FSIS Meat and Poultry Hazards and Controls Guide, which states \u201cappropriate screening procedure for monitoring equipment\u201d is a frequently used control for foreign material hazards when grinding products.", "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 9 of 12 6. Rework B: Pathogen outgrowth (Salmonella, Campylobacter) No Written Rework Procedures SOP for establishing rework procedures, lot, and temperature control. C: None P: None 7. Packaging and Labeling B: Pathogen outgrowth (Salmonella, Campylobacter) Yes Processing could result in product temperatures above 45\u00b0F. CCP 2

includes a measure of the product temperature as the ground turkey is packaged. Written Sanitation program for packaging operation. Yes CCP 2 C: None P: None 8. Storage and Distribution B: Pathogen Outgrowth (Salmonella, Campylobacter) No Pathogen outgrowth may result if temperatures are not maintained at levels to prevent bacterial multiplication. Product is packaged and placed in storage coolers or freezers to prevent product temperatures that promote pathogen outgrowth (Tompkin, R.B. 1996). Written Refrigerated Storage Conditions and Temperatures SOP including controls and verification. Written Cooler Sanitation SOP for cleaning of storage coolers\freezers. Written Product Loading SOP for monitoring truck holding temperature at loading. C: None P: None Written Product Loading SOP for monitoring the cleanliness of the product holding compartment at the time of loading." "Step Potential Hazard RLTO Justification \ Basis Controls CCP Page 10 of 12 9. Returned Product B: Pathogen Outgrowth (Salmonella, Campylobacter) No Reinspection SOP implemented before accepting returned product. Person(s) or business returning the product must demonstrate the product was held in the appropriate temperature range and in a sanitary manner. When such assurance is not available, returned product is rejected or destroyed. Opened packages are not accepted. Accepted product enters the appropriate step of the production system based on findings of product evaluation. Notify FSIS personnel when returned product has been accepted. Pathogen outgrowth may result if product temperature was not maintained at levels to prevent multiplication. (Tompkin, R.B. 1996). C: None P: Foreign material No Reinspection SOP implemented before accepting returned product. DATE: APPROVED BY:,"Page 11 of 12 EXAMPLE HACCP PLAN Raw, Non-Intact Turkey Control Point (CCP) Significant Hazard(s) Critical Limits for Each Control Measure Monitoring Procedures Corrective Action Verification Records What How Frequency Who CCP 1 Antimicrobial Application for Turkey Components24 Pathogens: Salmonella, Campylobacter25 The antimicrobial solution is mixed to an effective concentration of 650-750 ppm (FCN #).26 Solution is applied to all surfaces. Monitor the preparation and mixing of the antimicrobial solution. Assess the solution concentration at the point of application. Observe product during application of the solution. Record observations. Mix solution per manufacturer\u2019s instructions. Use titration kit to check the solution\u2019s antimicrobial concentration. Record observations on the Antimicrobial Check Form The preparation and mixing of the solution is observed once per shift. The concentration is checked once during each two-hour period of production. The application of the antimicrobial dip is observed once per shift. Designee If a deviation from the critical limit occurs, a supervisor will: 1. Hold all product produced after the last acceptable check until appropriate disposition taken (no product injurious to health will enter commerce); 2. Determine and eliminate the cause of the deviation; 3. Bring the CCP under control; 4. Take measures to prevent recurrence (9 CFR 417.3) Randomly, once per week, a supervisor observes each monitoring function. Once per week, a supervisor verifies the implementation of corrective actions for each critical limit deviation. Once per shift a supervisor reviews records per (9 CFR 417.4(a)(2)(iii)) Antimicrobial Check form Pre-shipment Records Records Review Form Verification Records Corrective Action Log DATE:

APPROVED: \_\_\_\_\_ 24 FSIS

Directive 7120.1, Safe and Suitable Ingredients Used in Meat, Poultry and Egg Products contains approved substances for use; however, each establishment must validate their own process for efficacy and control of biological hazards. See FSIS Compliance Guideline HACCP Systems

Validation. 25 See the FSIS Guideline for Controlling Campylobacter in Raw Poultry, and the FSIS Guideline For Controlling Salmonella in Raw Poultry for best practices and Campylobacter and Salmonella controls. 26 Scientific or technical support is required to validate the critical limits (parameters) for antimicrobial use, are part of the hazard analysis, and need to be maintained for the life of the HACCP plan (see FSIS Compliance Guideline HACCP Systems Validation).

NOTE: Critical operating parameters need to be addressed in this section as they are related to the scientific justification for use. Critical parameters include but are not limited to the following: type of sprayer, dip, volume, coverage, chemical contact time, solution temperature, etc. Define operational parameters which are specific to each establishment.", "Page 12 of 12 EXAMPLE HACCP PLAN Raw, Non-Intact Turkey Critical Control Point (CCP) Significant Hazard(s) Critical Limits for Each Control Measure Monitoring Procedures Corrective Action Verification Records What How Frequency Who CCP 2 Packaging and Labeling Pathogen: Salmonella, Campylobacter Temperature of product as it is packaged will be at 40\u00b0F or less. It has been updated in response to comments received on the previous version and renamed. In addition, the guideline has been revised to include recommendations from previous versions and new updates based on up-to-date science. The guideline also includes changes to improve its readability. This guideline represents FSIS\u2019s current thinking on these topics and should be considered usable as of its issuance. Establishments that used previous versions of Appendix B as support should either: \u2022 Update to this 2021 FSIS Stabilization Guideline (Revised Appendix B); or \u2022 Identify alternative support by December 14, 2022. The information in this guideline is provided to assist meat and poultry establishments in meeting the regulatory requirements. The contents of this document do not have the force and effect of law and are not meant to bind the public in any way. This document is intended only to provide clarity to industry regarding existing requirements under the regulations. Under the regulations, meat and poultry establishments may choose to implement different procedures than those outlined in this guideline, but they would need to validate and support how those procedures are effective. This guideline is focused on small and very small plants in support of the Small Business Administration\u2019s initiative to provide small businesses with compliance assistance under the Small Business Regulatory Enforcement Fairness Act (SBREFA). However, all meat and poultry establishments may apply the recommendations in this guideline. It is important that small and very small establishments have access to a full range of scientific and technical support, and the assistance needed to establish safe and effective Hazards Analysis and Critical Control Point (HACCP) systems. Although large plants can benefit from the information, focusing the guideline on the needs of small and very small establishments provides them with assistance that may be otherwise unavailable to them. Purpose of this Guideline This guideline contains information to assist meat and poultry establishments producing products that undergo cooking in complying with the HACCP regulatory requirements in 9 CFR 417. This guideline includes information on: \u2022 Biological hazards during stabilization. \u2022 Regulatory requirements associated with the safe production of stabilized heat-treated and partially heat-treated products. \u2022 Options establishments can use to prevent the growth of *C. perfringens* and other pathogens." "5 \u2022 Processes that do not have validated research available (Scientific Gaps), and options establishments can use until research is available. \u2022 Recommendations for evaluating cooling deviations. \u2022 Resources for alternative support. Establishments can always seek guidance from State university extension service specialists and HACCP Coordinators on developing programs and plans not provided in this guideline to comply with HACCP regulatory requirements. History of this Guideline and Reason for Reissuance In the 1980s, FSIS included prescriptive time and temperature cooling parameters in the regulations for cooked beef, roast beef, and cooked corned beef in response to several outbreaks associated with these products and research performed to determine how to prepare them safely (47 FR 31854; 48 FR 24314). When the Pathogen Reduction/\ Hazard Analysis and Critical Control Points (PR\HACCP) final rule published in 1996 and included performance standards for the production of certain meat and

poultry products, FSIS eliminated the prescriptive cooling regulations (to allow no growth of *C. botulinum* and no more than 1 log multiplication of *C. perfringens*; 9 CFR 318.17(a)(2), 9 CFR 318.23(c)(1), and 9 CFR 381.150(a)(2)). FSIS converted these former regulations to optional \u201cSafe Harbors\u201d in an appendix to the final rule called \u201cAppendix B\u201d (64 FR 732). Establishments have been using FSIS\u2019s Appendix B, as published in 1999, as support for cooling processes for many years. The original requirements and subsequent guidance have been important to prevent human illness outbreaks and ensure the production of safe food. Over time, FSIS determined that some of its recommendations in the 1999 version of Appendix B were vague, putting establishments at risk of producing unsafe products.

Additionally, some elements of the 1999 version of Appendix B guidance were misunderstood or overlooked, resulting in FSIS guidance being applied in ways that increased food safety risks to consumers and potential risks to industry, including the risk of recalls. FSIS also determined establishments were broadly applying the recommendations for operating parameters in Appendix B beyond those meat and poultry products it was originally designed to support. To provide the needed updates and clarifications, FSIS issued revisions of both its Cooking (revised Appendix A) and Stabilization (revised Appendix B) guidelines in 2017. The 2017 versions of the guidelines took into account new and emerging technologies, processes, and science. FSIS also expanded the information included in Appendix B beyond cooling to include other methods of stabilization. FSIS has updated this guideline in response to comments received on the 2017 version and has included additional options for cooling and hot-holding stabilization support based on updated science and technology. The Agency is releasing this current 2021 version of the Stabilization Guideline for Meat and Poultry Products (Revised Appendix B) to replace all previous versions."

"6 Changes from the Previous Versions This guideline dated December 14, 2021 is final. FSIS will update this guideline as necessary should new information become available. FSIS made the following changes to this guideline to reflect the comments received on the previous version during the comment period for the previous version and to include additional scientific information. For Appendix B, FSIS made changes to specify:

\u2022 Cooling options for both RTE and NRTE products that are cooked to lethality are included in Table 1 and incorporate the previous options, 1, 2, 3 and 4 as options 1.1, 1.2, 1.3 and 1.4.

\u2022 Cooling options for partially cooked products are included in a separate table (Table 2) and include former Option 1 as Option 2.1.

\u2022 Tables 1 and 2 list the critical operating parameters for each option.

\u2022 One additional option for partially cooked products, Option 2.2.

\u2022 That cooling in stage 1 of option 1.2 from 120 to 80 \u00b0F should occur in 1 hour.

\u2022 That the heating come-up-time (CUT) in Option 2.1 for partially cooked products should be limited to 1 hour between 50 and 130\u00b0F. FSIS extended the CUT up to 3 hours in Option 2.2 for partially cooked products, if the product meets the critical operating parameters for concentrations of salt, nitrite, and a cure accelerator sufficient for purpose.

\u2022 New options 1.5 \u2013 1.8 that provide additional cooling time during the first stage of cooling.

\u2022 That to use Option 1.3, establishments should incorporate at least 250 ppm sodium erythorbate or ascorbate, along with at least 100 ppm ingoing sodium nitrite (either from a purified or natural source such as celery powder).

\u2022 That natural sources of nitrite and ascorbate should not be mixed with purified or synthetic sources.

\u2022 FSIS removed the recommendation to cool from 120 to 80 \u00b0F in 2 hours in Option 1.4 and replaced it with the critical operating parameter that the process cause a continuous drop in product

temperature. To support all the cooling options, additional research and modeling results using up-to-date validated cooling models are included in Attachment B3. FSIS' Predictive Microbial Modeling Support for 1-Log Cooling Options (page 50).<sup>7</sup> To support common bacon and scrapple processes, FSIS updated references to research in Attachment B8. Using Journal Articles to Support Alternative Stabilization or Cooling Procedures (page 80) to address comments requesting support for these processes. Practical recommendations for improving product cooling in Attachment B4. Steps an Establishment Can Take to Cool Products More Rapidly. Where gaps exist (See Scientific Gaps as indicated in Table 3 (page 29)), recommendations from its older cooling guidance can be used until research is completed for: 1. Large mass non-intact products that cannot cool quickly enough to follow the new options in Table 1. 2. Partially heat-treated, smoked products that contain nitrite and erythorbate or ascorbate and have long heating come-up and cooling times and cannot follow the options in Table 2. 3. Smoked bacon that contains nitrite and erythorbate/ascorbate that cannot use Option 1.3 because lethal time and temperature combination is achieved but relative humidity is not addressed. 4. Immersion or dry-cured products that contain nitrite and use equilibration time instead of erythorbate or ascorbate but cannot meet cooling options without nitrite in Table 1 (for products cooked to full lethality) or Table 2 (for products not cooked to full lethality). 5. Products that contain nitrite and use equilibration time instead of erythorbate or ascorbate, but do not have a brine concentration of 6% to meet Option 1.4. 6. Scalded offal that cannot cool quickly enough to follow the new options in Table 2. For Appendix B, FSIS removed: Specific recommendations for obtaining a waiver to permit 2-Log growth of *C. perfringens* during cooling. This information was removed since it was interpreted to apply to all establishments when it was only intended for establishments that wanted to support a lower level of spores in their source product. In addition, FSIS has not received any waiver requests, but establishments may request a waiver in the future (9 CFR 303.1(h) and 9 CFR 381.3(b)). In addition to these changes, the guidelines format was restructured to make it easier to use as described in the next section.<sup>8</sup> How to Effectively Use this Guideline As explained above in the Changes from the Previous Versions, the guidelines format was restructured to make it easier to use. Specifically, the guideline is organized to include the following topics in the body of the guideline: Biological hazards during stabilization. Regulatory requirements associated with the safe production of stabilized heat treated and partially heat-treated products. Options establishments can use to prevent the growth of *C. perfringens* and other pathogens. Processes that do not have validated research available (Scientific Gaps), and options establishments can use until research is available. Recommendations for evaluating cooling deviations. Resources for alternative support. Information included in the body of the guideline is intended as scientific support that can be used alone by establishments to meet Element 1 of validation (9 CFR 417.4(a)(1)) and to support decisions in the hazard analysis (9 CFR 417.5(a)(1)). The following topics are included in Attachments to the guideline: Resources for alternative support. Recommendations for evaluating cooking deviations. Information provided in the attachments is not sufficient to use as sole support and additional documentation is needed. For example, this guideline contains attachments with summaries of scientific articles. However, the summaries are not considered adequate support on their own because they do not contain the details of each study. For this reason, establishments must have the full copy of

the article on-file as scientific support for their HACCP System. The summaries are provided to help establishments identify journal articles related to their process. Each establishment needs to determine if the operating parameters of a particular study match the establishment's process. Establishments are not limited to using the scientific articles listed and summarized as support. In addition, the guideline contains recommendations for evaluating product safety in the event of a deviation. This information is not considered adequate support on its own because establishments should perform predictive microbial modeling and may conduct sampling and testing to support product disposition. Other information included in attachments is intended to be supplementary.", "9 Questions Regarding Topics in this Guideline If after reading this guideline you still have questions, FSIS recommends searching the publicly posted Knowledge Articles (\u201cPublic Q&As\u201d) in the askFSIS database. If after searching the database, you still have questions, refer them to the Office of Policy and Program Development through askFSIS and select HACCP Deviation & HACCP Validation as the Inquiry Type or by telephone at 1-800-233-3935. Documenting these questions helps FSIS improve and refine present and future versions of the guideline and associated issuances.", "10 FSIS Stabilization Guideline for Meat and Poultry Products (Revised Appendix B) Background What is Stabilization? Stabilization is the process of preventing or limiting the growth of spore-forming bacteria capable of producing toxins either in the product or in the human intestine after consumption (See Attachment B1. Characteristics of Clostridial pathogens page 41 for more information about spore-forming bacteria). Establishments may use a variety of different stabilization processes, such as: \u2022 Cooling. \u2022 Hot-holding (e.g., hot-holding of soups prior to hot-fill packaging). \u2022 Meeting and maintaining certain pH, % brine (salt) concentration in the product, or water activity levels. Stabilization is an important food safety control of the growth of pathogens in food products. Products and Processes Covered by this Guideline This guideline addresses stabilization of meat and poultry products after a full or partial heat treatment is applied. Establishments may use FSIS Cooling Options in Table 1 for products that do not contain nitrite and erythorbate or ascorbate (i.e., Options 1.1., 1.2. 1.5-1.8), including for cooling of rice, pasta and bean products (see FSIS Support for Application of Options 1.1, 1.2, 1.5-1.8 to Rice, Pasta, and Beans page 61). Products Not Covered by this Guideline Fish of the order Siluriformes (e.g., catfish) are considered meat under the FMIA. However, fish of the order Siluriformes and fish products are not covered by this Stabilization Guideline because the options in the KEY DEFINITIONS Stabilization is the process of preventing or limiting the growth of spore-forming bacteria capable of producing toxins either in the product before consumption or in the human intestine after consumption. Establishments may use a variety of different stabilization processes, such as cooling, hot-holding, and meeting and maintaining certain pH or water activity levels. Bacterial spores are dormant cells that can survive environmental conditions that would normally kill bacteria. These conditions include high temperature, high UV irradiation, desiccation, chemical damage, and enzymatic destruction. The extraordinary resistance to such stresses makes spores of particular importance because they are not readily killed by many antimicrobial treatments, including traditional cooking.", "11 guideline have only been validated for livestock products. Establishments may use FDA's Fish and Fishery Products Hazards and Controls Guidance or Section 3-501.14 Cooling of the 2017 FDA Food Code as support for cooling of fish of the order Siluriformes. Cooling guidance found in the FDA Food Code is discussed further in

Attachment B6. Other Published Processing Guidelines for Cooling page 77. For more information on FSIS\2019 regulatory requirements related to fish of the order Siluriformes see FSIS Compliance Guideline for Establishments that Slaughter or Further Process Siluriformes Fish and Fish Products. Biological Hazards of Concern During Stabilization The following section is designed to complement FSIS\2019 Meat and Poultry Hazards and Control Guide and to further assist establishments in conducting a hazard analysis for heat-treated meat and poultry products as required by 9 CFR 417.2(a)(1) and for supporting decisions in the hazard analysis as required by 9 CFR 417.5(a)(1). The primary hazards of concern during cooling and hot holding are: \u2022 C. perfringens and \u2022 C. botulinum. Clostridia are Gram-positive, rod-shaped, spore-forming bacteria that can occur as either vegetative cells (active cells that can grow, multiply and produce toxin) or spores (dormant cells that are resistant to heat and other extreme conditions). Vegetative cells can produce spores and spores can germinate back into vegetative cells. Clostridia (both vegetative cells and spores) are usually found in soil and water. These are anaerobic organisms; in other words, they can grow without oxygen. Clostridia do not grow well in the presence of normal amounts of oxygen; however, they do not need a complete lack of oxygen to grow well. This is an important consideration for establishments as they assess hazards, design processes, and assess supporting documentation to prevent Clostridia growth and spore formation because it would not be appropriate to assume that Clostridia are not a hazard of concern just because oxygen is present. Even products that are exposed to oxygen may support Clostridia growth. Meat and poultry products may become contaminated with Clostridia during the slaughter and dressing process and by cross-contamination in the processing environment when insanitary conditions are present. Added ingredients, such as spices and herbs can contribute to the amount of Clostridia spores in raw formulated cooked\heat-treated meat and poultry products. For example, in one survey, C. perfringens spores were isolated from 80% of 54 different spices and herbs (Juneja and Sofos, 2010).", "12 Why Clostridia Spores Survive Cooking As explained above, raw meat and poultry products may become contaminated with Clostridia spores and vegetative cells. Heating meat and poultry products to full lethality (cooking) is generally sufficient to destroy vegetative cells; however, under these same conditions, spores may survive cooking and multiply during cooling when the conditions favor their growth (Figure 1). The destruction of vegetative cells (from Clostridia as well as bacteria such as Salmonella, Shiga toxin-producing Escherichia coli (STEC), and indigenous microflora) during heat treatment leaves little competition for the sporeforming pathogens to grow during cooling. Anaerobic, non-refrigerated conditions facilitate multiplication and growth of spore-forming pathogens. If cooling is rapid, growth can be limited to safe levels. However, if cooling is slow, excessive growth may occur. Similarly, situations where meat and poultry products cooked without reaching full lethality and then cooled could create an ideal environment for growth of C. perfringens and C. botulinum. This is because cumulative growth can occur over the course of the partial heating and cooling steps. Cooking by the consumer, retailer, or other end user may not eliminate these bacteria or the toxins that form in meat and poultry products especially if they grow to high levels. Therefore, it is important that an establishment producing meat and poultry products control bacterial growth in the products, to the extent possible, before they reach the end user or consumer. Figure 1. Schematic depicting how spores can form, germinate, and grow in meat and poultry products after heat is applied. C. perfringens and C. botulinum form spores that can survive cooking.

Spores can germinate and grow during cooling. Cooling products quickly, will limit pathogen growth and keep food safe.", "13 General Considerations for Designing HACCP Systems to Control the Growth of Clostridia Stabilization in the HACCP System FSIS has established performance standards in the regulations for the stabilization of specific heat-treated products as listed in Attachment B2. FSIS Stabilization Performance Standards or Targets for Clostridia Growth (page 47). These performance standards establish permissible levels of growth of spore-forming bacteria allowed during stabilization. \u2022 RTE cooked beef, RTE roast beef, RTE cooked corned beef must be stabilized to allow no multiplication of toxigenic microorganisms such as *C. botulinum* and no more than 1-Log multiplication of *C. perfringens* to comply with 9 CFR 318.17(a)(2). \u2022 RTE uncured beef patties must be stabilized to allow no multiplication of toxigenic microorganisms such as *C. botulinum* and no more than 1-Log multiplication of *C. perfringens* to comply with 9 CFR 318.23(c)(1). \u2022 RTE cooked poultry must be stabilized to allow no multiplication of toxigenic microorganisms such as *C. botulinum* and no more than 1-Log multiplication of *C. perfringens* to comply with 9 CFR 381.150(a)(2). \u2022 NRTE partially cooked and char-marked meat patties and partially cooked poultry breakfast strips must be stabilized to allow no multiplication of toxigenic microorganisms such as *C. botulinum* and no more than 1-Log multiplication of *C. perfringens* to comply with 9 CFR 318.23(c)(1) and 9 CFR 381.150(b). For products that are not subject to a performance standard, FSIS recommends the following pathogen Log reductions (i.e., targets) be achieved in order to support decisions in the hazard analysis (9 CFR 417.5(a)(1)): \u2022 For other NRTE, heat-treated meat and poultry products, FSIS recommends establishments allow no multiplication of toxigenic microorganisms such as *C. botulinum* and no more than 1-Log multiplication of *C. perfringens*. KEY DEFINITIONS Performance standards described in this guideline are quantifiable pathogen growth limit requirements set by FSIS for the stabilization of certain meat and poultry products. Targets described in this guideline are quantifiable pathogen growth limits set by the establishment to produce safe products in the absence of regulatory performance standards. Critical operating parameters are those parameters of an intervention that must be met for the intervention to operate effectively and as intended. Such parameters may include but are not limited to time, temperature, water activity, concentration, relative humidity, and type of equipment (to the extent that the use of different equipment would result in an inability to achieve the critical operating parameters of the study).", "14 An establishment should identify the performance standard (for products subject to the standard) or specific Log growth target (for other heat-treated products) its process is designed to achieve as part of its HACCP plan or supporting documentation to meet record-keeping requirements (9 CFR 417.5(a)(1)). In addition, according to 9 CFR 417.2(c)(3), establishments must design their critical limits for the critical control points (CCPs) to meet all applicable performance standards or targets. NOTE: If an establishment uses the stabilization options from this guideline, it does not need to indicate the specific Log growth that its process achieves in its HACCP plan or supporting documentation. It would be sufficient for the establishment to indicate that it uses the critical operating parameters from this guidance document. CCPs versus Prerequisite Programs Establishments have flexibility regarding how they address critical operating parameters in their HACCP systems. \u2022 If a critical operating parameter is addressed as part of a CCP, the establishment is required to list the critical limits (9 CFR 417.2(c)(3)), and support the monitoring procedures, and frequencies chosen for monitoring each CCP to ensure

compliance with the critical limits (9 CFR 417.2(c)(4) and 9 CFR 417.5(a)(2)). Establishments are required to calibrate process-monitoring instruments as part of ongoing verification activities (9 CFR 417.4(a)(2)). Furthermore, establishments are required to support their verification procedures and frequencies of those procedures per (9 CFR 417.5(a)(2)). \u2022 If a critical operating parameter is addressed in a prerequisite program, and the establishment determines that the implementation of that program results in potential hazards being not reasonably likely to occur, then it must have supporting documentation for the decisions made in the hazard analysis (9 CFR 417.5(a)(1)). If the establishment does not include the critical operating parameters in its HACCP plan or one or more prerequisite programs and has no documentation to show why they are not needed in its processes, FSIS will likely find that the establishment is not meeting the recordkeeping requirements of (9 CFR 417.5(a)(1)). Validation, Monitoring, Calibration, and Recordkeeping It is important the establishment\u2019s cooling procedures are designed to ensure all products limit the growth of spore forming pathogens and for the monitoring procedures to be designed to detect a deviation when it occurs. To achieve this, establishments should carefully consider the selection of the critical limit as well as the design of their monitoring procedures. Establishments are required to validate that their HACCP system works as intended to address these hazards (9 CFR 417.4(a)). For more information on validation see the, FSIS Compliance Guideline HACCP Systems Validation. To understand the situations", "15 when both RTE and NRTE products would be considered adulterated due to Clostridia outgrowth under the Federal Meat Inspection Act (FMIA) and Poultry Products Inspection Act (PPIA), refer to Attachment B2., subsections: What is the public health concern of *C. perfringens* and *C. botulinum* in RTE Products? (page 48) and What is the public health concern of *C. perfringens* and *C. botulinum* in NRTE Products (page 49). Below are specific considerations for monitoring the critical operational parameters of product temperature. \u2022 While cooling is a continuous process, FSIS recommends that establishments monitor temperature in two distinct temperature intervals, called stages, to better document pathogen control. This does not mean that cooling starts and stops at each of these stages. However, monitoring is performed at two different points. The first stage of cooling corresponds to the optimal growth temperatures for pathogens of concern (see Appendix B1. Subsection: Product Characteristics that Affect Clostridia Growth, page 42). Reducing time that the product spends in the first stage of cooling provides greater pathogen control. The second stage of cooling takes the product temperature down to the point where pathogens cannot grow, so it needs to be monitored as well. \u2022 FSIS recommends establishments measure the temperature of the product throughout cooling. If the scientific support in their validated system identifies multiple stages of cooling, establishments must ensure product is chilled to meet the time limit for each stage. During initial validation, establishments should initially gather sufficient time-temperature data to understand the rate of temperature change in each stage of cooling. For example, the establishment should determine whether the product cools down quickly at first and then takes longer as the process continues, or if it cools at the same rate throughout the entire process. The rate of temperature change throughout cooling can have a significant impact on the amount of growth of *C. perfringens* and *C. botulinum*. Even if two processes take the same total amount of time to chill product when the product starts at the same temperature, if the cooling rate is different, then KEY QUESTION Question: Are establishments required to use this Stabilization Guideline as support for cooling meat and poultry products?

Answer: No. Establishments are NOT required to use this guideline as scientific support for cooling and stabilization processes. Establishments may choose to adopt different procedures than those provided in the guideline; however, they would need to support that those procedures are effective to meet validation requirements and support decisions in their hazard analysis (9 CFR 417.4(a)(1) and 9 CFR 417.5(a)(1)). A few resources that may be used as alternative support for cooling processes have been included in this guideline, see Customized Processes and Alternative Support (page 26). (pag26)." "16 the amount of pathogen growth can vary significantly. FSIS recommends establishments gather time-temperature data in 15- to 30-minute increments when the product temperature is between 130\u00b0F and 80\u00b0F. The time-temperature data should be in 30- to 60-minute increments when the product temperature is between 80\u00b0F and final temperature (40\u00b0F or 45\u00b0F depending upon the option used). o This is particularly important for FSIS Option 1.2, since *C. perfringens* grows fastest at temperatures between 120 and 80\u00b0F. However, establishments are not required to demonstrate that every lot of the product is chilled from 120 to 80\u00b0F in one hour or less, if data is gathered during initial validation and as part of ongoing verification to support a reduced monitoring frequency (see FSIS HACCP Systems Validation Guideline). o If establishments choose not to measure each stage of cooling, they should recognize that a deviation may affect additional product and pathogen modeling may not be an available option to determine product disposition. \u2022 In addition, as part of the initial validation, FSIS recommends that the establishment use worst-case scenarios to ensure that the product will meet the critical operating parameters on an ongoing basis. Conditions affecting consistent cooling include: o Size, shape, and weight of product; o Stacking\storage in the cooler and the amount of product in the cooler; \u2022 For example, a relatively empty cooler might not cool at the same rate as an overfilled cooler. o Air velocity and initial temperature of the cooler\freezer; and o Product composition (e.g., fat level and moisture content). Worst-case scenarios should take into account all of these factors (i.e., largest size or weight product, fullest cooler, highest initial cooler temperature, etc.). For more information on factors that affect product cooling rate, see Attachment B4. Steps an Establishment Can Take to Cool Products More Rapidly (page 63). Establishments producing stabilized meat and poultry products are required to have sufficient monitoring equipment, including recording devices, to assure that the critical operating parameters of the stabilization processes\u2014including time, temperature, and pre-cooling conditions\u2014are being met (9 CFR 417.5(a)(2)). The establishment should take the normal variation of the monitoring equipment into account when designing the critical limits. For example, if a minimum internal temperature of 140\u00b0F is necessary to control pathogen growth while hot-holding a product and the thermometer has an accuracy of \u00b1 2\u00b0F, the critical limit should be set no lower than 142\u00b0F. The written reasoning and equipment specification materials are required to be kept as part of the establishment\u2019s supporting documentation (9 CFR 417.5(a)(2)). In addition, establishments are required to maintain documents supporting the selection of monitoring procedures and associated frequencies (9 CFR 417.5(a)(2)). It is important that establishments take into account variation within the cooling process", "17 when developing monitoring procedures to ensure they are sufficient to identify any deviations. Ultimately, the establishment should ensure that the whole HACCP system is operating as intended to produce a safe and wholesome product. Product Characteristics and Processes to Control Clostridia

**Growth** Several factors affect the growth of *C. perfringens* and *C. botulinum* during stabilization. These include the: \u2022 Product time-temperature profile. \u2022 pH. \u2022 % brine concentration in product. \u2022 Type and concentration of phosphates (wt\wt basis). \u2022 Water activity (aw). \u2022 Type and concentration of organic acid salts (e.g., lactate\diacetates and others). \u2022 Ingoing sodium nitrite and erythorbate or ascorbate concentrations. For more information on these factors\u2014including the use of natural sources of nitrite and ascorbate\u2014which effect Clostridia species growth see Attachment B1. Characteristics of Clostridial Pathogens (page 41). Much of the scientific support establishments can use to validate their process will include one or more of these factors. For more information on scientific support see FSIS Options for Stabilization (page 21) or Customized Processes and Alternative Support (page 27) of this guideline.", "18 FSIS Critical Operating Parameters for Stabilization (Revised Appendix B) Establishments have many options for the types of scientific support documentation that can be used to demonstrate that their stabilization process results in acceptable levels of Clostridia growth. Product characteristics (e.g. pH) and specific cooling schedules (e.g. Appendix B cooling options) are commonly used as critical limits. Product sampling results may not be used as scientific support for a stabilization process, because these results do not provide information regarding the level of growth allowed by the process. NOTE: FSIS is aware that several common processes cannot achieve the critical operating parameters in this guideline and scientific research is not readily available to support several common processes. For information on these processes\resultant products see Scientific Gaps Identified by FSIS (page 27) of this guideline. **Product Characteristics as Critical Limits** If heat-treated meat and poultry products are produced in a manner such that the final product has a certain specific characteristic or characteristics, then the growth of Clostridia is inherently inhibited; see Attachment B1. Characteristics of Clostridial Pathogens page 41 of this guideline. Establishments may use any one of the specific characteristics listed below as a sole critical limit to demonstrate Clostridia outgrowth is controlled provided, the characteristic is achieved before cooling: \u2022 pH: pH of 4.6 or less; or \u2022 Brine Concentration in Product:10% or more; or \u2022 Water activity (aw): A water activity of 0.92 or less. **KEY DEFINITIONS** Brine Concentration is a measure of the amount of salt in the water phase of the product. Brine concentration can\u2019t be determined by the formulation; it is a value calculated from the total salt content and total water content values obtained by a lab analysis. %

Processing Inspectors\u2019 Calculations Handbook Chapter 14 for more information.";"19 To use any of the above characteristics as a critical limit, it is very important that the product achieves the target value quickly, throughout the entire product, and before cooling.

Establishments that use a marinade or other solution to lower the pH of their product should be aware that it can take time for the product to equilibrate (balance) to the pH of the solution. If a product takes too long to equilibrate, significant growth of *C. perfringens* and *C. botulinum* can occur (see Chitterlings Example below). Establishments that use pH or aw as critical operating parameters for stabilization, may still need to cool their product in a timely manner (i.e., continuously) depending on the final pH or aw. Products that use low pH for stabilization should ensure the product has equilibrated prior to cooling. If the product cannot be equilibrated prior to cooling, then the product should be cooled using different scientific support such as one of the cooling options in this guideline. Establishments that choose to stabilize through reduced water activity after a cooking lethality treatment should ensure that product temperature remains at 140°F or higher until water activity decreases below the growth limit of *Clostridium perfringens* and *Clostridium botulinum* (< 0.93) to prevent outgrowth as discussed. Establishment may be able to monitor oven temperatures in lieu of product temperature as discussed in the 2020 Cooking Guideline. Product stabilized by one of these characteristics should be cooled continuously because the products could become contaminated with *Listeria monocytogenes* (Lm) or *Staphylococcus (S. aureus)* during cooling, and these pathogens may be able to grow in the product depending on the final pH or aw. For example, while *C. perfringens* and *C. botulinum* cannot grow in products with an aw < 0.93, *S. aureus* can grow in products stored aerobically with an aw as low as 0.86 (ICMSF, 1996). If FSIS collects a RTE sample that is positive for Lm during cooling, FSIS will verify whether the establishment has identified and eliminated the root cause of the incident as part of corrective actions (9 CFR 417.3(b)) and that the establishment can still support its cooling procedure.

Importance of Achieving target pH or water activity before cooling: Chitterlings Example FSIS verification activities have identified a trend in establishment sampling results that show high levels of *C. perfringens* (2 to 4-Log CFU/g) in chitterlings that establishments try to stabilize using low pH brine. FSIS analyses uncovered a recurring incorrect assumption by establishments that the pH of the chitterlings is reduced to 4.6 as soon as the brine is added to the hot

chitterlings, when it actually may take several hours for the pH to be reduced, during which time the product is cooling and outgrowth of *C. perfringens* is occurring. As stated above, products should achieve a pH  $\geq 4.6$  before cooling to achieve food safety control. These findings are important because the levels of *C. perfringens* found through testing indicate growth may occur at a level of public health concern when FSIS's critical operating parameters are not followed." "20 FSIS Hot-Holding Options Hot-holding is the process of holding meat and poultry products that have been cooked to full lethality at hot temperatures (typically above  $130^{\circ}\text{F}$ ) prior to distribution. Often, products such as meals or meat pies are held at hot temperatures and then shipped hot to customers (either consumers or to retailers, such as convenience stores) for immediate consumption. Soups may also be hot-held prior to hot-filling into the final packaging. FSIS is including in this guideline recommendations for hot-holding that were previously found in FSIS Directive 7110.3 Time\Temperature Guidelines for Cooling Heated Products, which has been cancelled. Hot-holding Temperatures Uncured cooked products should be held for: Up to 4 hours if kept above  $130^{\circ}\text{F}$ , or An extended period if kept above  $140^{\circ}\text{F}$ . If product drops below  $130^{\circ}\text{F}$  for over 30 minutes, the processor should: Continuously cool it to meet the critical operating parameters of the chosen support document, immediately reheat it to  $160^{\circ}\text{F}$ , or Discard it. NOTE: Establishments should choose a hot holding critical operating temperature above  $140^{\circ}\text{F}$  unless they have established consistent temperature control over every portion of the product. Thus, establishments should maintain product above  $140^{\circ}\text{F}$  when in transit, in the absence of container temperature monitoring, and in similar cases where control procedures are not established and monitored. Establishments should also have ongoing communication with the retailer to support that the product is being hot-held appropriately. Intermediate Holding Temperatures Occasionally, some establishments will need to hold product at an intermediate temperature ( $< 60^{\circ}\text{F}$ ) prior to completion of cooling. When this occurs, FSIS recommends: Products are heated above  $155^{\circ}\text{F}$ , then promptly cooled from  $130^{\circ}\text{F}$  to  $60^{\circ}\text{F}$  within 2 hours. These products may be held for up to 4 hours, if they are: Kept below  $60^{\circ}\text{F}$  during the 4 hours, Protected from post-cooking contamination, and At the end of the 4-hour holding period, are cooled to  $40^{\circ}\text{F}$  within 2 hours." "21 FSIS Cooling Options Tables 1 and 2 summarize all of the FSIS cooling options that limit the growth of *C. perfringens* to  $\leq 1.0\text{-Log}_{10}$  colony forming units per gram<sup>1</sup> (CFU/g) and allow for no multiplication of *C. botulinum*. These options are intended for products that are cooled in a continuous manner and do not apply to processes where cooling starts and stops multiple times or processes where the product is cooked to a full lethality, cooled, and then partially heat-treated and cooled again. For processes with multiple heating steps, FSIS recommends establishments use microbial modeling to design custom cooling schedules as described in Attachment B5. Predictive Microbial Modeling (page 64). Gray boxes in Tables 1 and 2 are parameters that changed from the 1999 version of Appendix B or are new. The food safety significance of these changes is explained on page 28 of this guideline. FSIS considers the cooling options in Tables 1 and 2 to be validated process schedules.2 Establishments that struggle to meet any of the cooling options in Tables 1 and 2 may find Attachment B2. Stabilization Requirements for Specific Meat and Poultry Products (page 47) useful. Other establishments may use processes that FSIS has identified as a Scientific Gap (page 27). Further information about using FSIS's Cooling Tables is included below. 1 In

the rest of this document, Log<sub>10</sub> colony forming units per gram (Log<sub>10</sub> CFU/g) will be annotated simply as \u201cLog.\u201d All notations of \u201cLog\u201d should be read as in the unit Log<sub>10</sub> CFU/g unless other information is provided.

2 The scientific research and data used to develop each option is included in Attachment B3. FSIS\u2019 Predictive Microbial Modeling Support for 1-Log Cooling Options, page 68. Importance of Pathogen Modeling for Multiple Cooling Steps: Tamales Example Many establishments produce a meat or poultry product that involves multiple heating and cooling steps. One example is an establishment that will cook meat to lethality and then cool the meat product. During that first cooling, *C. perfringens* may grow up to 1-Log. The establishment will then reheat the meat product, such as a tamale filling. The tamale with the filling will be heated and then cooled. Spore-forming pathogens, already at 1-Log of growth from the first cooling will then have the opportunity to grow during non-lethal reheating and the 2nd cooling. This could result in sufficient growth to create a public health concern. Establishments that choose to reheat a meat or poultry product may be able to design the process so that the cumulative growth from all of the heating and cooling steps is less than 1-Log. In order to design a process with multiple heating and cooling steps, FSIS recommends the establishment use predictive microbial models. For more information on how to perform predictive microbial modeling for multiple cooling steps see the Section titled Using Predictive Microbial Models to Assess Growth of Clostridia when a Process Incorporates Multiple Heat Treatments page 69 of this guideline.", "2 To Use FSIS Cooling Tables 1 and 2: First, choose the applicable table. Table 1 should be used if the product is cooked to full lethality (RTE or NRTE). \u2022 Cooked to full lethality refers to achieving lethality following validated critical operating parameters such as those in the FSIS Cooking Guideline for Meat and Poultry Products (Revised Appendix A). FSIS recognizes that products may continue to be cooked for longer dwell times or to higher temperatures for quality reasons. To apply Table 1, the establishment must support that its products meet all critical operating parameters from their chosen scientific support for cooking to lethality. For example, if the supporting document is the FSIS Cooking Guideline, the cooking process must address relative humidity and come-up-time (CUT), in addition to internal endpoint time-temperature. \u2022 Products that receive a lethality treatment that achieves sufficient Log reduction of *Salmonella* may be classified as RTE or NRTE as long as they are not defined by a standard of identity as a RTE product. For more information on product reclassification see Attachment 1.2 on pages 22-23 and Appendix 1.2 on pages 28-29 of the 2014 FSIS Compliance Guideline: Controlling *Listeria monocytogenes* in Post-lethality Exposed Ready-to-Eat Meat and Poultry Products. Table 2 should be used if the product does not receive a full lethality treatment (NRTE). \u2022 Many products may be heated during processing to temperatures that do not achieve full lethality. These products are also referred to as partially heat-treated. Examples include smoked breakfast sausages, smoked pork bellies, and par-fried breaded patties or nuggets (cooked enough to set the breading). \u2022 Table 2 includes heating CUT as a critical operating parameter to control the cumulative outgrowth of *C. perfringens* and *C. botulinum* during the entire process, since any pathogen growth during heating will not be eliminated due to the lack of a full lethality time-temperature (See Why Clostridia Spores Survive Cooking page 12). Second, choose the option that matches the process, and follow all critical operating parameters. \u2022 To use the FSIS Cooling Options as support for decisions in the hazard analysis, establishments must follow all critical operating parameters in the chosen option. If an

establishment does not follow all critical operating parameters of an option, it should provide support for why that option should still limit growth of *C. perfringens* to 1.0-log and allow for no multiplication of *C. botulinum*.<sup>1,2</sup> Temperatures referred to in Tables 1 and 2 are internal product temperatures. However, establishments may provide support for monitoring surface temperatures of intact products (such as beef brisket or a picnic shoulder that is not injected or vacuum tumbled). The internal temperature of product that is deboned and rolled or non-intact should be taken at the coldest point of the product interior (See Key Definitions to the right for an explanation of intact vs. non-intact). Monitoring for cooling is performed at two different points. The first stage of cooling is the most important for stabilizing the product, as it is the optimal growth temperature for pathogens of concern. If an establishment can shorten the time it takes to complete the first stage of cooling, the establishment may add the remaining time to the second stage of cooling. However, the total cooling time would remain the same as the original option. For helpful tips on how to cool products faster, refer to Attachment B4. Steps an Establishment Can Take to Cool Products More Rapidly (page 63). In the event that a process deviates from FSIS's Cooling Options, the establishment may use its monitoring records to perform predictive microbial modeling to develop support for product disposition. For more information see Attachment B5. Predictive Modeling, subsection Corrective Actions to Perform When a Cooling Deviation Occurs, page 71.

**KEY DEFINITIONS** Intact refers to products where the interior remains protected from pathogens migrating below the exterior\outside. Non-Intact refers to products where pathogens may have been introduced below the surface. Examples include products that have been mechanically tenderized or vacuum tumbled. Come-up-time (CUT) refers to the amount of time product temperature is between 50 to 130°F while heating.<sup>3,4,5</sup> Table 1. FSIS Cooling Options for Products Cooked to Full Lethality

Option	1.1	1.2	1.3	1.4	1.5	1.6	1.7
1st stage of cooling (temperature reduction\time)	130 to 80°F / 1.5 hours	80 to 40°F / 5 hours	130 to 80°F / 6.5 hours	130 to 80°F / 15 hours	130 to 80°F / 10 hours	126 to 80°F / 7 hours	126 to 80°F / 6.5 hours
2nd stage part of cooling (temperature reduction\time)	80 to 40°F / 1 hour	80 to 40°F / 5 hours	80 to 40°F / 6 hours	80 to 40°F / 20 hours	80 to 40°F / 5 hours	80 to 40°F / 3.25 hours	80 to 55°F / 3.75 hours
Total cooling time	130 to 80°F / 1.5 hours	80 to 40°F / 5 hours	130 to 80°F / 6.5 hours	130 to 80°F / 20 hours	130 to 80°F / 5 hours	126 to 80°F / 3.25 hours	126 to 80°F / 3.75 hours
Chilling must begin within	90 minutes after the cooking cycle is complete	90 minutes after the cooking cycle is complete	90 minutes after the cooking cycle is complete	90 minutes after the cooking cycle is complete	90 minutes after the cooking cycle is complete	90 minutes after the cooking cycle is complete	90 minutes after the cooking cycle is complete

5 FSIS's Scientific Support and references used to develop these options can be found in (Attachment B3. FSIS's Predictive Microbial Modeling Support for 1-Log Cooling Options,

page 68). 6 Nitrite and erythorbate\ascorbate may be added using natural or synthetic sources (page 45). 7 This option does not require a cure accelerator due to the high brine concentration inhibiting spore outgrowth. Nitrite is optional if the product has a aw \u2264 0.92.","25 Table 2. FSIS Cooling Options for Products that Do NOT Receive a Full Lethality8,9 Option Critical Operating Parameters Pre-Cooling Conditions 1st stage of cooling 2nd stage of cooling Total cooling time Option 2.1 CUT between 50- 130\u00b0F \u2264 1 hour 130 to 80\u00b0F \u2264 1.5 hours 80 to 40\u00b0F \u2264 5 hours \u2264 6.5 hours Option 2.2 CUT between 50- 130\u00b0F \u2264 3 hours; and \u2265 2% salt; and \u2265 150 ppm sodium nitrite10 and cure accelerator or natural source of ascorbate (sufficient for purpose) 130 to 80\u00b0F \u2264 1.5 hours 80 to 40\u00b0F \u2264 5 hours \u2264 6.5 hours 8 Options and operating parameters that changed since 1999 Appendix B are bolded and shaded grey. 9 FSIS\u2019 Scientific Support and references used to develop these options can be found in (Attachment B3. FSIS\u2019 Predictive Microbial Modeling Support for 1-Log Cooling Options, page 68). 10 Nitrite and erythorbate\ascorbate may be added using natural or synthetic sources (page 45).","26 Food Safety Significance of Changes Why do partially cooked products have fewer options for cooling (only those in Table 2)? In general, for partially cooked meat and poultry products, the cooling options are more limited because without a validated lethality step, cumulative growth of *C. perfringens* and *C. botulinum* can occur over the course of the partial cooking or heating and cooling steps. Cumulative growth allows for more vegetative cells in the finished product and having a vegetative high cell count increases illness risk. To limit cumulative growth, FSIS recommends a heating CUT for partially cooked products. CUT as used in this guideline refers to the time the product temperature is between 50 and 130\u00b0F during heating, because this is the primary range of concern for pathogen growth. While CUT is important for fully cooked products, the CUT is not addressed in stabilization options for fully cooked products cooked to full lethality, because all vegetative cells of *C. perfringens* and *C. botulinum* are destroyed by the cooking process. Note that on page 24 of the FSIS Cooking Guideline, FSIS has recommended CUTs for fully cooked products cooked to full lethality to ensure *S. aureus* growth is controlled. Why did FSIS change Option 1.2 to include a first-stage of cooling (120 to 80 \u00b0F in \u2264 1 hour)? When Appendix B was developed as a safe harbor to the stabilization performance standards, FSIS added the note that \u201cif product remains between 120 to 80\u00b0F more than one hour, compliance with the performance standard is less certain.\u201d However, validated pathogen modeling and research from 2018 supports that cooling between 120 to 80\u00b0F for 3-4 hours can result in 2 to 3-Log growth of *C. perfringens* (Smith, et al., 2018), which would definitely exceed the performance standard or target. One outbreak occurred from a RTE large diameter turkey loaf product that can take several hours to cool between 120 to 80\u00b0F. FSIS has included options in Table 1 that extend the time during 120 to 80\u00b0F as much as possible when considering other intrinsic product characteristics, such as pH. Why does Option 1.3 include the recommendation to add at least 250 ppm erythorbate or ascorbate, in addition to the original recommendation to add at least 100 ppm nitrite? Research from 2015 found that erythorbate or ascorbate is needed in addition to sodium nitrite to control the growth of *C. perfringens* to safe levels. Why does Option 1.4 no longer apply to products formulated with \u2265 120 ppm of sodium nitrite or its equivalent and a brine concentration of 3.5% or more? Currently available validated pathogen modeling programs have indicated these parameters may result in > 2.0-log *C. perfringens*

growth. Why does Option 1.4 no longer have an option for the first stage of cooling to cool from 120 to 80°F in 2 hours or less? FSIS determined that these parameters were based on *S. aureus* growth on the surface of the product which is not the hazard this Option is designed to address. Instead, establishments should demonstrate a continuous drop in temperature without the need to demonstrate any particular timeframe is met between 120 to 80°F.<sup>27</sup> Customized Processes and Alternative Support FSIS recognizes that not all products can be stabilized using the FSIS critical operating parameters included in this guideline. To assist establishments in stabilizing their products, FSIS has identified resources that could be used as scientific support. Resources in the attachments include information on the following:

\u2022 Customized Cooling Schedule: Establishments may design a customized cooling plan with multiple cooling and heating steps using validated pathogen models. See Attachment B5.

Predictive Microbial Modeling page 64.

\u2022 Processing Guidelines: Other government agencies have published validated cooling guidelines that establishments could use as scientific support. See Attachment B6. Other Published Processing Guidelines for Cooling page 77.

\u2022 Challenge Studies: Establishments could conduct challenge studies to determine if their proposed process would meet the performance standard. See Attachment B7. Using Challenge Studies to Support Alternative Stabilization\Cooling Procedures page 78.

\u2022 Journal Articles: Establishments could identify a published journal article that shows a specific process meets the performance standard and use this as scientific support. See Attachment B8. Using Journal Articles to Support Alternative Stabilization\Cooling Procedures page 80.

Scientific Gaps Identified by FSIS FSIS has identified several common stabilization processes that can\u2019t achieve the critical operating parameters included in this guideline. FSIS encourages establishments to conduct challenge studies when other support is not available (page 78). However, the Agency realizes it may not be cost effective for establishments to conduct individual challenge studies for commonly produced meat and poultry products. To address these common processes that lack readily available scientific support, FSIS has identified and communicated scientific gaps and is working to facilitate filling these gaps. FSIS posted research priorities on its website to communicate clear research needs with USDA Agricultural Research Service (ARS) and academic researchers. As additional data becomes available, FSIS will update the recommendations for these scientific gaps with the latest available scientific support. An establishment producing products using processes that fall under an identified scientific gap may continue to use the critical operating parameters in this guideline as scientific support (see Table 3). Table 3 also describes specific vulnerabilities with using the gaps as scientific support and recommends steps to reduce the vulnerabilities. In addition to those specific vulnerabilities, FSIS has the following concerns with establishments continuing to process products using the critical operating parameters in Table 3:

\u2022 Use of these critical operating parameters represents a vulnerability because these processes have not been validated to address all hazards of concern.<sup>28</sup>

If a process deviation occurs for a process that is listed as a scientific gap, it is unlikely an establishment would be able to identify adequate support for product safety without performing product testing.

\u2022 If FSIS or the establishment collects a RTE product sample that is positive for a pathogen or the product is implicated in a food safety investigation (i.e., is associated with reports of illness or outbreak), FSIS would verify, as part of the corrective actions (9 CFR 417.3(b)), that the establishment can demonstrate that inadequate lethality or stabilization was not the root cause of the positive

sample or the confirmed illness or outbreak, which it would need to do if it wants to continue to use the older recommendation. As additional data becomes available, FSIS will change the recommendations for processes that fall under one of these scientific gaps. NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Additionally, Products Not Covered by this Guideline would NOT be adequately supported by the critical operating parameters listed in Table 3. FSIS will update this guideline as more research becomes available and new options can be developed. Scientific gaps are processes which have not been validated to achieve stabilization and address all potential hazards during cooling, but establishments may continue to use this guidance as support for those processes to allow additional time for research to be conducted.", "NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 3). 29 Table 3: Scientific Gaps where Critical Operating Parameters from Older Guidance May be Used Scientific Gaps Example Products Critical Operating Parameters from Older Guidance Vulnerability with Continuing to Follow Parameters from Older Guidance

1. Large mass non-intact products that cannot cool quickly enough to follow the new options in Table 1. Processes that meet this gap include all of the following: Cooked to full lethality. Non-intact. Large product size or weight >4.5 inches or >8 pounds. Non-intact turkey breast > 8 pounds or roast beef that is > 4.5 inches thick. Chilling begins within 90 minutes after the cooking cycle is complete. Cooling occurs from 120 to 55°F in 6 hours. Continuous chilling until 40°F. These parameters do not take into account the amount of time product remains between 120 to 80°F. If products take more than 1 hour to cool between 120 to 80°F, excessive growth of *C. perfringens* and *C. botulinum* may occur, particularly if products are non-intact. In the event of a deviation, if product takes more than 1 hour to cool between 120 to 80°F, it is unlikely that pathogen modeling will support product safety, and sampling may be needed. To minimize this vulnerability, establishments may choose to validate any of the following: If possible, limit the time between 120°F to 80°F to no more than 2.5 hours or between 80°F and 55°F for more than 3.5 hours (6 hours total cooling time) to limit *C. perfringens* growth to 2-log or less. If that is not possible, identify the shortest amount of time it is thermodynamically possible to go from 120 to 80°F, and monitor this point on a routine basis. Conduct finished product testing for *C. perfringens* (see page 74). Add antimicrobials. Reduce product diameter or thickness. Perform a challenge study or pathogen modeling for particular product.", "NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 3). 30 Scientific Gaps Example Products Critical Operating Parameters from Older Guidance Vulnerability with Continuing to Follow Parameters from Older Guidance

2. Partially heat-treated, smoked products, that contain nitrite and erythorbate/ascorbate and have long come-up and cooling times in Table 2. Processes that meet this gap include all of the following: Partial heat treatment, Smoked. Slower CUT (greater than 3 hours in Option 2.2). Formulated with at least 100 ppm nitrite or nitrate (synthetic or natural). Formulated

with at least 250 ppm 250ppm erythorbate or ascorbate (synthetic or natural). Hams containing nitrite and erythorbate or ascorbate. Apply Option 1.3 to this partially heat-treated product\* specifically: 130 to 80°F in 5 hours and 80 to 40°F in 10 hours, with 15 hours total cooling time. \*NOTE: No CUT parameter. These parameters may allow excessive cumulative growth of *C. perfringens* during heating and cooling if CUT is not addressed, although smoke, nitrite, and erythorbate/ascorbate may help limit growth. To minimize this vulnerability, establishments may choose to validate any of the following: \u2022 Cook the product to lethality, which would allow a CUT of up to 6 hours between 50-130°F per FSIS Cooking Guideline. This product may then apply Option 1.3 without being in a Scientific Gap for Stabilization. \u2022 Perform a challenge study or pathogen modeling for a particular product.

\*NOTE: Products cooked to full lethality which exceed a CUT of 6 hours between 50-130°F may meet the conditions for a Cooking Guideline Scientific Gap. Note: While this gap may be applied to bacon there is research that supports some common partially heat-treated bacon processes.", "NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 3). 31 Scientific Gaps Example Products Critical Operating Parameters from Older Guidance Vulnerability with Continuing to Follow Parameters from Older Guidance 3. Smoked bacon, that contains nitrite and erythorbate/ascorbate that cannot use Option 1.3 because lethal time and temperature combination is achieved but relative humidity is not addressed. Processes that meet this gap include all of the following: \u2022 Lethal time and temperature combination but relative humidity has not been addressed (therefore, product is not considered to achieve \u201cfull lethality\u201d)\*. \u2022 Formulated with at least 100 ppm nitrite or nitrate (synthetic or natural). \u2022 Formulated with at least 250 ppm erythorbate or ascorbate (synthetic or natural). \*Note: relative humidity does not need to be monitored when cooking meat or poultry products that are 10 pounds or more in an oven maintained at or above 250 °F (121 °C). Bacon containing nitrite and erythorbate or ascorbate. Apply Option 1.3 to this partially heat-treated product\* specifically: 130 to 80°F in 5 hours and 80 to 40°F in 10 hours, with 15 hours total cooling time. \*NOTE: No CUT parameter These parameters may allow insufficient surface lethality of pathogens such as *Salmonella*. To minimize this vulnerability, establishments may choose to validate any of the following: \u2022 Cook the product to lethality, which would include using a humidity option. Apply Option 1.3 without being in a Scientific Gap for Stabilization. \u2022 Perform a challenge study or pathogen modeling for a particular product.

\*NOTE: Products cooked to full lethality which exceed a CUT of 6 hours between 50-130°F may meet the conditions for a Cooking Guideline Scientific Gap. Note: While this gap may be applied to bacon there is research that supports some common partially heat-treated bacon processes.", "NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 3). 32 4. Immersion or dry-cured products that contain nitrate and/or nitrite and use of equilibration time instead of erythorbate or ascorbate but cannot meet cooling options without nitrite in Table 1 or Table 2. Processes that meet this gap include all of the following: \u2022 A heat treatment (full or partial). \u2022 Immersion or

dry-cured. \u2022 Slower CUT (greater than 3 hours in Option 2.2). \u2022 Formulated with at least 100 ppm nitrite or nitrate (synthetic or natural). \u2022 Formulated without erythorbate or ascorbate (synthetic or natural). \u2022 Allow equilibration time for the cure reaction to occur (e.g., at least 2 to 3 days). Immersion or dry-cured bacon and ham containing nitrite without erythorbate or ascorbate. Apply Option 1.3 to product without erythorbate or ascorbate\* specifically: 130 to 80\u00b0F in \u2264 5 hours and 80 to 40\u00b0F in \u2264 10 hours, with 15 hours total cooling time \*NOTE: No CUT parameter for partially heat-treated products. One vulnerability is the potential for excessive cumulative growth of *C. perfringens* during heating and cooling if CUT is not addressed. To minimize this vulnerability, establishments may choose to: \u2022 Cook the product to lethality, which would allow a CUT of up to 6 hours between 50-130\u00b0F per FSIS Cooking Guideline. NOTE: Ensuring adequate equilibration time is still critical (see second vulnerability). A second vulnerability is the minimum equilibration time needed to ensure nitrite conversion to produce antimicrobial activity without a cure accelerator is unknown. To minimize this vulnerability, establishments may choose to validate any of the following: \u2022 Equilibration time for salt and nitrite to penetrate throughout product and time to allow nitrite to convert to active form and limit growth or. \u2022 Perform a challenge study or pathogen modeling for a particular product. NOTE: Products cooked to full lethality which meet this Stabilization Guideline Scientific Gap may also meet the conditions for a Cooking Guideline Scientific Gap if CUT exceeds 6 hours.", "NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 3). 33 Scientific Gaps Example Products Critical Operating Parameters from Older Guidance Vulnerability with Continuing to Follow Parameters from Older Guidance 5. Products that contain nitrite and use equilibration time instead of erythorbate or ascorbate, but do not have a brine concentration \u2265 6% to meet Option 1.4. Processes that meet this gap include all of the following: \u2022 Any heat treatment, \u2022 Pumped with nitrite, \u2022 Formulated with at least 120 ppm nitrite or nitrate (synthetic or natural), \u2022 Formulated without erythorbate or ascorbate (synthetic or natural), \u2022 Brine concentration of 3.5% or more and \u2022 Allows equilibration time for the cure reaction to occur (e.g., at least 2 to 3 days). Pumped ham containing nitrite without erythorbate or ascorbate. Apply Option 1.4 to product\* with \u2265 120 ppm nitrite and \u2265 3.5% brine concentration 120 to 40\u00b0F \u2264 20 hours; Continuous temperature drop \*NOTE: No CUT parameter for partially heat-treated products There is a vulnerability that there may be excessive cumulative growth of *C. perfringens* during heating and cooling if CUT is not addressed, although smoke and nitrite may help limit growth. To minimize this vulnerability, establishments may choose to validate any of the following: \u2022 Equilibration time for salt and nitrite to penetrate throughout product and time to allow nitrite to convert to active form; \u2022 Cook the product to lethality, which would allow a CUT of up to 6 hours between 50 to 130\u00b0F per FSIS Cooking Guideline; or. \u2022 Perform a challenge study or pathogen modeling for a particular product. NOTE: Products cooked to full lethality which meet this Stabilization Guideline Scientific Gap may also meet the conditions for a Cooking Guideline Scientific Gap.", "NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not

Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 3). 34 Scientific Gaps Example Products Critical Operating Parameters from Older Guidance Vulnerability with Continuing to Follow Parameters from Older Guidance

6. Scalded offal that cannot cool quickly enough to follow the new options in Table 2. Processes that meet this gap include all of the following: \u2022 Edible offal which is partially heat-treated or scalded. Scalded beef tripe or pork stomachs. Product chilled to 45\u00b0F in \u2264 24 hours. These parameters do not take into account the amount of time product remains between 120 to 80\u00b0F. If products take more than 1 hour to cool between 120 to 80\u00b0F, excessive growth of *C. perfringens* and *C. botulinum* may occur. In the event of a deviation, if product takes more than 1 hour to cool between 120 to 80\u00b0F, it is unlikely that pathogen modeling will support product safety, and sampling may be needed. To minimize this vulnerability, establishments may choose to validate any of the following:

\u2022 If possible, limit the time between 120\u00b0F to 80\u00b0F to no more than 2.5 hours nor between 80\u00b0F and 55\u00b0F for more than 3.5 hours (6 hours total cooling time) to limit *C. perfringens* growth to 2-log or less. If that is not possible, identify the shortest amount of time it is thermodynamically possible to go from 120 to 80\u00b0F, and monitor this point on a routine basis.

\u2022 Conduct finished product testing for *C. perfringens* (see page 74).

\u2022 Add antimicrobials.

\u2022 Perform a challenge study or pathogen modeling for a particular product.

NOTE: Establishments may limit the time between 120\u00b0F to 80\u00b0F by increasing the amount of dry ice when packing the product, packing offal in smaller boxes, or not stacking as many boxes on a pallet which can impede airflow.

Characteristics of Clostridial Pathogens

Public Health Risk in Meat and Poultry Clostridia can be a problem in foods other than heat-treated meat and poultry products, such as improperly canned low acid foods ( $\text{pH} > 4.6$ ), raw honey, and fermented, smoked, and salted seafood. Most illness outbreaks associated with *C. perfringens* are traced to food served in restaurants, homes for the elderly, or at buffet-style gatherings. In fact, *C. perfringens* is often referred to as the “food service germ,” because outbreaks may occur if the products are held at room temperature for too long or they are cooled in large batches, allowing pathogens to grow. A limited number of *C. perfringens* illnesses are attributed to products produced under FSIS inspection. A 2005 FSIS risk assessment found that stabilization at processing plants accounted for 0.05% and 0.4% of predicted *C. perfringens* illnesses at 1-Log and 2-Log allowable growth, respectively. There have been a limited number of *C. perfringens* outbreaks associated with commercially produced meat and poultry products in the U.S. Specifically, one outbreak was associated with *C. perfringens* from a commercially produced RTE turkey loaf product (CDC, 2000; personal communication, R.F. Woron, N.Y. State Department of Health, August 2002). *C. perfringens* and *C. botulinum* cause human illness in different ways. *C. perfringens* causes illness when people ingest a large infectious dose of 6-Log/g or higher ( $10^6 \text{ CFU/g}$ ). These high levels of cells occur when the product remains at growth temperatures for too long, allowing the vegetative cells to grow. If a large enough dose of *C. perfringens* is ingested, vegetative cells may survive the environment in the stomach and briefly persist in the gut. These conditions cause this pathogen to form spores and produce a toxin in the gut. *C. perfringens* is estimated to cause 965,958 illnesses, including 438 hospitalizations and 26 deaths in the U.S. each year (Scallan et al., 2011). *C. botulinum* causes human illness when people ingest a potentially deadly neurotoxin (botulin) that is produced in affected food. After 12 to 36 hours following ingestion, botulin can cause muscle paralysis and suffocation with as little as 1 nanogram (ng) of toxin per kilogram (kg) of body weight. Botulin is considered one of the most toxic naturally occurring toxins. While human botulism cases are rare in the U.S., it is estimated that *C. botulinum* causes approximately 55 illnesses, including 42 *C. perfringens* grows the fastest of the spore-forming pathogens. It is a good indicator of food safety during stabilization.", "42 hospitalizations and 9 deaths each year (Scallan et al., 2011). There are six distinct Clostridia that produce botulinum toxin; two of which are associated with food: *C. botulinum* Group I (proteolytic) and *C. botulinum* Group II (non-proteolytic). Proteolytic *C. botulinum* is the most common group associated with illness from meat and poultry products in the United States. Although non-proteolytic *C. botulinum* is typically associated with fish and marine products, there have been several recent outbreaks in Europe associated with non-proteolytic *C. botulinum* and home-prepared (salted) ham (Peck et al., 2015). Because of the potency of the neurotoxin that this pathogen produces, it is critically important to control *C. botulinum* in food products. NOTE: *B. cereus* is a spore-forming bacterium that may also be a hazard of concern during severe deviations of cooling and hot-holding (e.g., where pathogen modeling shows the potential for  $10^3$  3-Log *C. perfringens* growth). *B. cereus*, if allowed to grow to high levels (typically 5-Log CFU/g) can produce emetic and diarrheal toxins in the food. However, *B. cereus* is not discussed in further detail in this guideline because if *C. perfringens* and *C. botulinum* growth are adequately controlled or prevented using options discussed in this guideline, then *B. cereus* growth will be adequately addressed as well. For this reason, FSIS did not identify outgrowth of *B. cereus* as a hazard of concern at the cooling/stabilization step in

the FSIS Meat and Poultry Hazards and Control Guide. Product Characteristics that Affect Clostridia Growth Below is a review of the critical operating parameters that are important for cooling heat-treated RTE and NRTE meat and poultry products. Product time-temperature profile An establishment's cooling schedule should take into account the amount of time a product takes to cool in certain temperature ranges associated with growth as follows:

The optimum growth temperature for *C. perfringens* is 109.4 °F (43 - 47°C), and the lower and upper growth limits are 50°F and 126°F (6°C and 54°C), respectively (Solberg and Elkind, 1970). The optimum temperature for growth for *C. botulinum* (proteolytic, which is the kind found in meat) is 95 °F (35 - 40°C), and the lower and upper growth limits are between 50°F and 122°F (10.0°C and 50.0°C), respectively (ICMSF, 1996). In addition, establishments should also design their cooling process to match the timetemperature profile in their scientific support. General Considerations for Designing HACCP Systems to Control the Growth of Clostridia contains additional recommendations for initial validation of cooling processes (page 13).<sup>1</sup>

The lower and upper pH growth limits for *C. perfringens* are 5.0 and 8.3, respectively. For *C. botulinum* (proteolytic, which is the kind found in meat), the lower and upper pH growth limits are 4.7 and 9, respectively (Hauschild, 1989; Labbe, 1989). As the pH decreases, the growth of *C. perfringens* and *C. botulinum* becomes slower. Brine concentration in product As the brine concentration increases (defined on page 18), the growth of *C. perfringens* and *C. botulinum* becomes slower. The minimum inhibitory brine concentration is 8% for *C. perfringens* (ICMSF, 1996) and 10% for *C. botulinum* (proteolytic) (Lund and Peck, 2000). The type and concentration of phosphate (wt/wt basis) A high phosphate concentration, 0.4-0.5 %, can have a limited effect on inhibiting the growth of *C. perfringens* in the product (Akhtar et al., 2008; Singh et al., 2010). Water activity (aw) As the water activity decreases, growth of *C. perfringens* and *C. botulinum* slows. The water activity limit for growth and germination of both *C. perfringens* and *C. botulinum* is 0.93. (ICMSF, 1996). Therefore, a water activity less than 0.93 is required to control the growth and toxin formation of Clostridia. The type and concentration of sodium lactate/diacetates Many establishments are now adding sodium lactate/diacetate or other organic salts as an antimicrobial agent to RTE meat or poultry products to meet the requirements of Alternative 1 or Alternative 2, Choice 2 of the Lm regulations (9 CFR 430.1 and 9 CFR 430.4). Establishments should ensure that the sodium lactate/diacetate or organic acid salt used in their process matches the antimicrobial used in their scientific support and should also ensure or consider the following:

That the scientific support is based on the specific trade name for the sodium lactate/diacetate or organic acid salt product used during product formulation;

That the active component concentrations (%) of sodium lactate/diacetate or organic acid salt in the commercially formulated product used during product formulation is the same as that in the scientific support; and

The concentration (wt/wt basis) of the sodium lactate/diacetate or organic acid salt in the product after formulation. Several published research articles have shown lactate/diacetate products and other organic salts can significantly inhibit the growth of *C. perfringens* during cooling, and even extend the chilling times from 15 to 21 hours for cooked, uncured meat or poultry products. (See the research articles summarized in Attachment B8. Using Journal Articles to Support Alternative Stabilization or Cooling Procedures, Table 15. that include lactate/diacetate products; page

82).","44 Ingoing sodium nitrite\ nitrate concentration and erythorbate or ascorbate Sodium nitrite slows the growth of *C. perfringens* and inhibits the growth and toxin formation of *C. botulinum*, if it is used in combination with a cure accelerator, such as sodium erythorbate or ascorbate or a high salt concentration (King et al., 2015). The amount of sodium nitrite and erythorbate or ascorbate needed will depend on the establishment\u2019s scientific support. Establishments should be aware that a minimum of 120 ppm ingoing nitrite should be added in all cured \u201cKeep Refrigerated\u201d products, unless the establishment can demonstrate that safety is assured by some other preservation process, such as thermal processing, pH, or moisture control. This 120 ppm recommendation is based on safety data reviewed when the bacon standard was developed (FSQS, 1978). Natural Sources of Nitrite and Ascorbate Research supports that naturally occurring sources of nitrite (e.g., from celery powder) are functionally equivalent to pure sodium nitrite for inhibiting the growth of *C. perfringens* if a sufficient quantity of a natural source of ascorbate (e.g., from cherry powder) is also used (King et al., 2015). Similar research has not been performed on the growth of *C. botulinum*. However, FSIS has determined from expert opinion that nitrite from natural sources will likely also control the growth of *C. botulinum*, if sufficient quantities of nitrite and ascorbate are used (J. Sindelar, personal communication, 2015). When using natural sources of nitrite, establishments must provide support that the level of nitrite and ascorbate used are effective to control the growth of *C. perfringens* and *C. botulinum*. Natural sources of nitrite are generally available in two forms: \u2022 Vegetable juices and powders that contain sodium nitrate. The establishment should use these products in combination with a bacterial culture that reduces the nitrate to nitrite in the product. When using natural sources of sodium nitrate, the quantity of sodium nitrite present is not known because the conversion of nitrate to nitrite that occurs in the product as a result of the presence of a bacterial culture can occur at varying rates. Because the nitrate to nitrite conversion rate may vary from batch to batch, there is concern about obtaining a consistent conversion and thus the sodium nitrite level in the product (Jackson et al., 2011b). \u2022 Vegetable juices and powders in which the sodium nitrate has been preconverted to sodium nitrite by the supplier so there is no need to add a bacterial Synthetic versions of cure accelerators may not be used with natural sources of nitrate or nitrite.", "45 culture. Because the sodium nitrate has been pre-converted, the concentration of sodium nitrite in the natural source is known. However, the amount may still vary between lots of the natural source due to differences in the conversion rate. Establishments should ensure the levels of sodium nitrite are safe and suitable according to FSIS Directive 7120.1, \"Safe and Suitable Ingredients Used in the Production of Meat and Poultry Products\" and 9 CFR 424.21(c)). If establishments are using natural sources of sodium nitrite, FSIS recommends that, when possible, establishments use natural sources of sodium nitrite with known concentrations of nitrite. By knowing the concentration of nitrite, establishments can ensure they neither use too little nor too much in their formulation. In order to use one of the cooling Options for products formulated with sufficient nitrite, establishments must support that they have added sufficient quantities of nitrite (e.g., for Option 1.3 at least 100 ppm nitrite). (Note that mixing natural sources of nitrate\ nitrite with synthetic versions of a cure accelerator would not be eligible for using option 1.3.) Establishments using nitrite may need to request this information from the supplier. Suppliers of sodium nitrite with known concentrations may supply this information as either: \u2022 Certificate of Analysis (COA) for each lot that states the sodium

nitrite in parts per million. An establishment would then need to calculate the quantity of nitrite to add to a given formulation in order to obtain the final ingoing concentration. See the Processing Inspectors\2019 Calculations Handbook for example calculations on page 11; or \2022 Standardized formulation directions for the natural source of nitrite (e.g. in a Letter of Guarantee or LOG). Some suppliers standardize the concentration of nitrite from lot to lot. These suppliers may provide formulation directions to achieve a specific concentration of nitrite, e.g., "Add 1 pound of [the blend] to 100 pounds of meat block." The establishment should maintain documentation of this final concentration achieved in the formulation.", "46 Natural Sources of Nitrite and Ascorbate \2013 Approvals and Labeling Celery powder and other natural sources of nitrite are approved by FSIS and FDA for use as antimicrobials and flavorings but are not approved as curing agents. Cherry powder and other natural sources of ascorbate are also approved for use as antimicrobials and flavorings but are not approved as cure accelerators. Ingredients approved for use as curing agents and cure accelerators are listed in 9 CFR 424.21(c) and the FSIS Directive 7120.1, Safe and Suitable Ingredients Used in the Production of Meat and Poultry Products. According to 9 CFR 424.21(c) cure accelerators may only be used if the product contains an approved curing agent. Therefore, synthetic versions of cure accelerators may not be used with natural sources of nitrate or nitrite as these are not approved as curing agents. Celery powder and other natural sources of nitrite are considered safe and suitable as antimicrobials, if used in combination with a natural source of ascorbate, such as cherry powder (See FSIS Directive 7120.1, Safe and Suitable Ingredients Used in the Production of Meat and Poultry Products). Celery powder may be added to meat and poultry products as a flavoring in accordance with 9 CFR 317.2(f)(1)(i)(B) and 9 CFR 381.118(c)(2) along with other natural sources of nitrite, such as beet juice and sea salt. Because celery powder and other natural sources of nitrite are not currently approved for use in 9 CFR 424.21(c) as curing agents, products that are required to contain curing agents and cure accelerators as part of a standard of identity in 9 CFR 319 or 9 CFR 317.17(b), but instead are formulated with natural sources of nitrite and ascorbate, must be labeled as "\201cuncured\201d under 9 CFR 319.2. Also, the label must contain the statement "\201cno nitrates or nitrites added\201d (9 CFR 317.17) that is qualified by the statement "\201cexcept for those naturally occurring in [name of natural source of nitrite such as celery powder]\201d as to not be considered misbranded due to false and misleading labeling under 9 CFR 317.8. For example, hot dogs and corned beef that contain celery powder instead of sodium or potassium nitrite, and cherry powder instead of ascorbate, must be labeled as "\201cuncured\201d" and contain the qualifying statement "\201cexcept for those naturally occurring in celery powder.\201d It would not be appropriate to label products with natural sources of nitrite with other terms such as "\201cnaturally cured\201d or "\201calternatively cured.\201d

NOTE: Products formulated with natural sources of nitrate and ascorbate that contain an amount of salt sufficient to achieve a brine concentration of 10% or more are exempted from the "\201cUncured\201d and accompanying "\201cno nitrates or nitrites added\201d statement and the qualifier labeling requirement per 9 CFR 317.17(c)(3).", "47 Attachment B2. Stabilization Requirements for Specific Meat and Poultry Products To ensure safety of heat-treated RTE meat and poultry products, FSIS has developed performance standards and recommended targets, for *C. perfringens* and *C. botulinum* growth in RTE and NRTE products. By designing their HACCP systems to meet these standards, establishments should be able to

avoid producing adulterated product (See: What is the public health concern of *C. perfringens* and *C. botulinum* in RTE Products? (page 48). As described under the section titled Stabilization in the HACCP System (page 13) of this guideline, for each biological hazard identified, establishments must design their HACCP systems to meet applicable performance standards or targets for reduction or prevention. For stabilization, targets are used by the establishment to demonstrate that its processes prevent the outgrowth of Clostridia to acceptable levels and prevent any outgrowth of botulinum. Whether an establishment must meet a required performance standard or identify a target, depends on whether the meat or poultry products are RTE or NRTE, and whether the products are subject to a regulatory stabilization performance standard. Table 4 lists the regulatory performance standards for specific meat and poultry products and describes the recommended targets for other RTE meat and poultry products and other NRTE, heat-treated meat and poultry products. Table 4. Stabilization performance standards and recommended targets for Clostridia growth If an establishment produces: Then its stabilization treatment must: RTE cooked beef RTE roast beef RTE cooked corned beef Allow no multiplication of toxigenic microorganisms such as *C. botulinum* and no more than 1-Log multiplication of *C. perfringens* to comply with 9 CFR 318.17(a)(2). RTE uncured beef patties Allow no multiplication of toxigenic microorganisms such as *C. botulinum* and no more than 1-Log multiplication of *C. perfringens* to comply with 9 CFR 318.23(c)(1). RTE cooked poultry Allow no multiplication of toxigenic microorganisms such as *C. botulinum* and no more than 1-Log multiplication of *C. perfringens* to comply with 9 CFR 381.150(a)(2). Other RTE meat products Consider the food safety hazards that are reasonably likely to occur in stabilization processes and establish steps to prevent, eliminate, or reduce those hazards to an acceptable level (9 CFR 417.2). FSIS recommends that establishments set a target to allow no more than a 1-Log multiplication of *C. perfringens* within the product and no multiplication of *C. botulinum*.," "48 If an establishment produces: Then its stabilization treatment must: NRTE partially cooked and char-marked meat patties, and partially cooked poultry breakfast strips Allow no multiplication of toxigenic microorganisms such as *C. botulinum* and no more than 1-Log multiplication of *C. perfringens* to comply with 9 CFR 318.23(c)(1) and 9 CFR 381.150(b). Other NRTE, heat-treated meat and poultry products Consider the food safety hazards that are reasonably likely to occur in stabilization processes and establish steps to prevent, eliminate, or reduce those hazards to an acceptable level (9 CFR 417.2). FSIS recommends that establishments set a target to allow no more than a 1-Log multiplication of *C. perfringens* within the product and no multiplication of *C. botulinum*. NOTE: The recommendation that the stabilization of NRTE meat and poultry products should limit the growth of *C. perfringens* and *C. botulinum* to the same levels in RTE meat and poultry products is consistent with guidance for controls in any raw meat or poultry process. In both cases, the establishment needs to document in its hazard analysis the necessary controls that must be maintained to minimize microbial growth to a level such that customary cooking practices would be sufficient to make the product safe. As described in 9 CFR 303.1(h), the Administrator may in specific classes of cases waive for limited periods any provisions of the regulations to permit experimentation so that new procedures, equipment, and/or processing techniques may be tested to facilitate definite improvements. What is the public health concern of *C. perfringens* and *C. botulinum* in RTE Products? Certain pathogens, including *Salmonella* and Lm, when present in a RTE meat or poultry product at any level, cause the product to be adulterated since consumption of the

product would be \u201cinjurious to health\u201d as per 21 U.S.C. 601(m)(1) and 453(g)(1)). Other pathogens, such as *C. perfringens*, are only a public health concern when growth occurs at levels that could lead to toxin formation; this indicates the products were prepared, packed, or held under insanitary conditions as per 21 U.S.C. 601(m)(4) and 453(g)(4). \u2022 For *C. perfringens*, spore levels found in raw meat and poultry are usually 2-3Log. These spores can survive cooking and germinate into vegetative cells during cooling (see page 12). If conditions during cooling allow for 3-Log growth or higher of these vegetative cells, then there is a public health concern because this would result in total levels of > 5-Log. At 5-Log, a toxin could be produced in the gut and cause illness. \u2022 For *C. botulinum*, conditions permitting spore germination and any growth of vegetative cells in the product are a public health concern because the toxin is "the most toxic natural substance known to humankind (Montville and Matthews, 2008). FSIS considers predictive modeling results with mean growth > 0.30-Log to be evidence of *C. botulinum* growth. What is the public health concern of *C. perfringens* and *C. botulinum* in NRTE Products? NRTE products that are contaminated with toxins such as the *botulinum* toxin are adulterated because cooking by consumers may not destroy the toxins, rendering the products injurious to health (21 U.S.C. 601(m)(1) and 453(g)(1)). In addition, if levels of growth occur that would be considered a public health concern (i.e., \u2265 3-Log of *C. perfringens*; or > 0.30-Log of *C. botulinum*), the product would be adulterated. In this situation, products would also be adulterated because they were prepared, packed, or held under insanitary conditions (21 U.S.C. 601(m)(4) and 453(g)(4)). NOTE: Examples of NRTE meat and poultry products include char-marked patties, partially cooked poultry breakfast strips, or products like hams or sausage that are cooked to a lethal time-temperature, but the establishment chooses to reclassify as NRTE.

*C. perfringens*: Some growth is acceptable before the product is considered adulterated. *C. botulinum*: Any level of growth is a concern and makes the product adulterated.", "50 Attachment B3. FSIS\u2019 Predictive Microbial Modeling Support for 1-Log Cooling Options This section contains the supporting documentation FSIS used to develop its 1-Log cooling options. A summary of each option is provided with the original journal articles used to develop the option. Also included is the most current research and pathogen modeling to support each option. All pathogen modeling FSIS performed was based on linear cooling in each stage. Also, the modeling was based on the use of a worst-case scenario pH of 6.2 and a salt concentration of 1% (Mohr et al., 2015). In addition to the modeling results, a figure showing the modeling output was also included for each option. This Appendix also includes FSIS Support for Application of Options 1.1, 1.2, 1.5-1.8 to Rice, Pasta, and Beans page 61. FSIS\u2019 Support for Option 1.1. Table 5. Summary of Option 1.1 (for products cooked to full lethality). Option Pre-Cooling Conditions 1st Stage of Cooling 2nd Stage of Cooling Total Cooling Time Option 1.1 130 to 80\u00b0F \u2264 1.5 hours 80 to 40\u00b0F \u2264 5 hours \u2264 6.5 hours The original option was developed using research found in: \u2022 Blankenship, L.C., Craven, S.E., Leffler, R.G., Custer, C. 1988. Growth of *Clostridium perfringens* in cooked chili during cooling. *Applied Environmental Microbiology*. 54(5):1104-1108. \u2022 Thompson, D.R., Willardsen, R.R., Busta, F.F., Allen, C.E. 1979. *Clostridium perfringens* population dynamics during constant and rising temperatures in beef. *Journal of Food Science*. 44(3):646-651. Up-to-date validated modeling provided the following results for products cooked to full lethality: \u2022 ComBase Perfringens Predictor Results = 0.52-Log growth (see Figure 2 for modeling output.)", "51 Figure 2. FSIS\u2019 Support for Option 1.3 Table 7. Summary of Option 1.3 (for products cooked to full lethality). Option Pre-Cooling Conditions 1st Stage of Cooling 2nd Stage of Cooling Total Cooling Time Option 1.3 \u2265 100 ppm sodium nitrite and \u2265 250 ppm sodium ascorbate or erythorbate 130 to 80\u00b0F \u2264 5 hours 80 to 45\u00b0F \u2264 10 hours \u2264 15 hours The original option was developed using research found in: \u2022 Roberts, T.A., Gibson, A.M., Robinson, A. 1981. Factors controlling the growth of Clostridium botulinum types A and B in pasteurized, cured meats: Part I. Growth in pork slurries prepared from \u2018low\u2019 pH meat (pH range 5.5\u20136.3). International Journal of Food Science & Technology. 16(3):239-266. \u2022 Roberts, T.A., Gibson, A.M., Robinson, A. 1981. Factors controlling the growth of Clostridium botulinum types A and B in pasteurized, cured meats: Part II. Growth in pork slurries prepared from \u2018high\u2019 pH meat (pH range 6.3\u20136.8) International Journal of Food Science & Technology, 16: 267-281.", "53 Up-to-date validated modeling provides the following results for products cooked to full lethality: \u2022 Results of modeling using the ComBase Perfringens Predictor ranged from 3.92Log C. perfringens growth for a product with 1% salt to 2.8-Log C. perfringens growth for a product with 2% salt concentration. Due to the high levels of predicted growth for C. perfringens, a figure of the modeling output has not been included in the guideline. FSIS decided, however, to still include the option itself in the guideline because the modeling is likely overestimating growth as follows: 1. The modeling was based on a worst-case salt scenario and cured products have higher salt concentrations. The modeling was based on the use of a worst-case scenario pH of 6.2 and a salt concentration of 1%. However, many cured products have higher salt concentrations inherent to their formulation or as a result of processing (Desmond, 2006); and. 2. The modeling does not take into account the role of cure accelerators that have been found to increase the effectiveness of nitrite. Research by King et al., 2015 supports that products formulated with at least 100 ppm sodium nitrite and at least 250 ppm erythorbate or ascorbate that are cooled following FSIS Option 1.3 allow \u2264 1-Log C. perfringens growth. The research supports that other combinations of nitrite and erythorbate or ascorbate are effective at limiting the growth of C. perfringens. Although the research was performed with a poultry product, the authors indicated this was chosen as a worst-case scenario itself and that the results also apply to meat products (Personal Communication, 2017). FSIS\u2019 Support for Option 1.4 Table 8. Summary of Option 1.4 (for products cooked to full lethality) Option Pre-Cooling Conditions 1st Stage of Cooling 2nd Stage of Cooling Total Cooling Time Option 1.4 \u2265 40 ppm sodium nitrite and \u2265 6% brine concentration OR aw \u2264 0.92 120 to 40\u00b0F \u2264 20 hours; Continuous temperature drop Not Applicable \u2264 20 hours The original option was

\u2264 3.25 hours; Continuous chilling until 40\u00b0F \u2264 6 hours Option 1.8 is a modification of Option 1.2 developed using validated modeling. Up-to-date validated modeling provides the following results for products cooked to full lethality: \u2022 ComBase Perfringens Predictor Results = 0.97-Log growth (see Figure 9 for modeling output).", "59 Figure 9. ComBase Perfringens Predictor Modeling Output for Option 1.8. FSIS\u2019 Support for Option 2.1 Table 13. Summary of Option 2.1 (for products not cooked to full lethality). Option Pre-Cooling Conditions 1st Stage of Cooling 2nd Stage of Cooling Total Cooling Time Option 2.1 CUT between 50 - 130\u00b0F \u2264 1 hour 130 to 80\u00b0F \u2264 1.5 hours 80 to 40\u00b0F \u2264 5 hours \u2264 6.5 hours Option 2.1 is a modification of Option 1.1 for products not cooked to full lethality. The original option (Option 1.1) was developed using research found in: \u2022 Blankenship, L.C., Craven, S.C., Leffler, R.G., and Custer, C. 1988. Growth of Clostridium perfringens in Cooked Chili during Cooling. Appl. Environ. Microbiol. 54:1104-1108; and \u2022 Thompson, D.R., Willardsen, R.R., Busta, F.F., Allen, C.E. 1979. Clostridium perfringens population dynamics during constant and rising temperatures in beef. Journal of Food Science. 44(3):646-651. Option 2.1 was developed using validated modeling. To develop the critical operating parameter to limit the CUT between 50 to 130\u00b0F to one hour, FSIS used the SmithSchaffer Model because this model allows input of data as the product temperature increases (during the heating CUT) and input of data as the product temperature decreases (during cooling). The application of the Smith-Schaffner Model with a one- hour CUT followed by the cooling process in Option 1.1 resulted in a 1.13-Log", "60 cumulative increase in C. perfringens. This is slightly above the regulatory requirement of no more than a 1-Log multiplication of C. perfringens for partially heat-treated products (9 CFR 318.23(c)(1) and 9 CFR 381.150(a)(2)). However, the modeling was performed based on a worst-case time-temperature profile assuming linear heating and cooling. Normally, meat and poultry products heat up and cool down exponentially. Linear modeling of the heating come up and cool down result in underestimating pathogen growth during the short heating come up period but overestimating pathogen growth during the longer cool down period, resulting in an overall overestimation of pathogen growth. Therefore, FSIS considers this modeling result fail-safe (that is a result that is not accurate in modeling terms but that errs on the side of the product being safe). FSIS\u2019 Support for Option 2.2 Table 14. Summary of Option 2.2(for products not cooked to full lethality). Option Pre-Cooling Conditions 1st Stage of Cooling 2nd Stage of Cooling Total Cooling Time Option 2.2 CUT between 50 - 130\u00b0F \u2264 3 hours and \u2265 2% salt and \u2265 150 ppm sodium nitrite and cure accelerator or natural source of ascorbate (sufficient for purpose) 130 to 80\u00b0F \u2264 1.5 hours 80 to 40\u00b0F \u2264 5 hours \u2264 6.5 hours Option 2.2 is also a modification of Option 1.1 for products not cooked to full lethality. Option 2.2 was also developed using validated modeling. This option was developed based on the use of the ARS PMP Online Cooling Model for Growth of C. perfringens in Cooked Beef supplemented with NaCl, Sodium nitrite, and Sodium pyrophosphate, which allows for input of the heating CUT, the cooling time, and NaCl (salt) and nitrite concentrations. The ARS cooling model estimates the growth of C. perfringens to be 1.03-Log based on modeling in a conservative manner. The ARS cooling model is more conservative when compared against predictions from the validated ComBase Perfringens Predictor (see Figure 10 for modeling output).", "61 Figure 10. ARS PMP Online Cooling Model for Growth of C. perfringens in Cooked Beef Supplemented with NaCl, Sodium nitrite, and

Sodium pyrophosphate Modeling Output for Option 2.2. FSIS Support for Application of Options 1.1, 1.2, 1.5-1.8 to Rice, Pasta, and Beans As stated in the section titled Products and Processes Covered by this Guideline, page 10, establishments may use FSIS Cooling Options in Table 1 for products that do not contain nitrite and erythorbate or ascorbate (i.e., Options 1.1, 1.2, 1.5-1.8) or for the cooling of rice, pasta and bean products. This recommendation is based on the scientific rationale that the time and temperature conditions that would generally limit the growth of *C. perfringens* to 1-Log or less would also effectively limit the growth of *Bacillus cereus* (*B. cereus* is a spore-former that is a greater hazard of concern than *C. perfringens* in rice, pasta, and bean products) and prevent multiplication of *C. botulinum*, since these pathogens generally grow more slowly than *C. perfringens*. For example, the shortest generation time (the time it takes to double in population) for *C. perfringens* under optimum growth temperatures (i.e., 43°C to 47°C) is approximately seven (7) minutes in ground beef (Willardson, et al., 1978), whereas the shortest generation time for *B. cereus* ranged from 18 to 27 minutes in tryptic soy broth (TSB)<sup>62</sup> and rice under optimum growth temperatures (i.e., 35°C to 45°C) (Johnson, et al., 1983). In addition, the cooling options in Table 1 for products that do not contain nitrite and erythorbate or ascorbate are similar to the FDA Food Code cooling recommendations which are designed to control the growth of all spore-forming bacterial pathogens including *B. cereus* in all cooked products (see Attachment B6. Other Published Processing Guidelines for Cooling, page 77).<sup>63</sup>

Attachment B4. Steps an Establishment Can Take to Cool Products More Rapidly Some establishments may have challenges meeting the cooling recommendations in this guideline, particularly for large mass products. For products that are close to meeting the time-temperature parameters for the cooling options in this guideline, establishments may benefit from critically examining their cooling process and system and making minor improvements such as:

- Making sure the cooling system is operating properly.
- Ensuring cooler door seals and gaskets are in good repair and properly seal when each door is closed.
- Pre-chilling the cooler before loading the product.
- Using a lower temperature setting in the cooler.
- Increasing airflow (e.g., adding a fan) to speed cooling.
- Leaving more space between products to allow increased air circulation between products.
- Allowing space between product and the walls, floors, and ceiling to improve air circulation.
- Agitating or stirring liquid products while cooling.
- Cooling product before packaging, stacking, or palletizing because stacks of product can insulate those products in the middle and inhibit cooling. May also make smaller stacks of product because smaller pieces or smaller groups of products cool faster.
- Reducing the amount of product in each batch or lot placed in the cooler at one time to reduce the total heat load to be removed.
- Taking steps that would decrease the temperature of the product prior to placing it in the cooler to reduce the heat load on the cooling system. For example, apply a liquid cooling procedure (e.g., cold brine shower, ice bath) or dry ice to rapidly cool the product prior to placing it in the cooler.
- Making minor production changes to reduce product size or diameter (e.g., by cutting large roasts into smaller portions or using a smaller size casing for sausages), provided these changes do not impact product quality.<sup>64</sup>

Attachment B5. Predictive Microbial Modeling and Corrective Actions Following a Deviation This appendix on predictive modeling includes the following several sections:

- Recommendations when Conducting Predictive Microbial Modeling
- Validated Pathogen Models
- Assessing Growth of Clostridia when a Process Incorporates Multiple Heat

Treatments \u2022 Corrective Actions to Perform When a Cooling Deviation Occurs Predictive food microbiology uses models (i.e., mathematical equations) to describe the growth, survival, or inactivation of microbes in food systems based on knowledge of the intrinsic and extrinsic factors of the food over time. Establishments can use predictive microbial models to help guide the design of a customized cooling process for processes that can\u2019t meet the critical operating parameters recommended in this guideline. Predictive microbial models can also be used to support product safety in the event of a cooling deviation, potentially preventing the need to perform sampling. There are many free predictive microbial models available to establishments either online or through a download. Establishments should not rely on the results of a predictive model alone unless the model has been validated for the particular food of interest. Note that there are several validated predictive models available for assessing *C. perfringens* growth. Recommendations when Conducting Predictive Microbial Modeling FSIS recommends that the establishments abide by the following principles when choosing and using a predictive microbial model to assure they model useful scientific support. 1. Use a model that has been validated for the product of interest. 2. Conduct modeling using at least five time-temperature data points. 3. Conduct modeling based on the worst-case cooling time-temperature profile for the product of interest. 4. Input accurate pH and salt concentrations, if included in the model; and 5. Maintain the results of the modeling electronically or via a hardcopy file. More detail on each of these principles is below: 1. Use a model that has been validated for the product of interest. Do not rely solely on a model unless the model has been validated for the particular food of KEY DEFINITIONS Intrinsic factors are those parameters inherent to a food that affect the growth of microorganisms. Examples of intrinsic factors include pH, moisture content, salt concentration, water activity, and nutrient content. Extrinsic factors are those parameters that are external to the food that affect the growth of microorganisms. Examples of extrinsic factors include, temperature of storage, time of storage, and relative humidity. KEY DEFINITIONS Intrinsic factors are those parameters inherent to a food that affect the growth of microorganisms. Examples of intrinsic factors include pH, moisture content, salt concentration, water activity, and nutrient content. Extrinsic factors are those parameters that are external to the food that affect the growth of microorganisms. Examples of extrinsic factors include temperature of storage unit, time of storage, and relative humidity.","65 interest. A validated cooling model is a model in which predictions have been found to agree with or are more conservative than the actual observed results. If a model has not been validated for a particular food of interest, establishments need to provide additional documentation to support the results from the model (e.g., sampling data or comparison with other model results). \u2022 These four cooling models have been validated for assessing the growth of *C. perfringens* in cooked\heat-treated meat and poultry products: 1. ComBase Perfringens Predictor Model a. uncured and cured meat, and b. poultry 2. USDA ARS Predictive Microbiology Information Portal (PMP Online) models for: a. cooked, uncured beef, pork, and chicken; b. cured pork and beef; and c. cooked beef supplemented with NaCl, sodium nitrite, and sodium pyrophosphate; 3. USDA ARS Pathogen Modeling Program (download version 7.0\8.0) models for: a. cooked, cured beef and chicken; and 4. Smith-Schaffner Model\u2014Version 3 a. uncured meat and poultry products \u2022 This cooling model failed validation testing and is not recommended: ARS *C. perfringens* in beef broth model. This model has been found to typically under-predict the growth of *C. perfringens* (Mohr et al., 2015).

Because the model failed to be validated, it has been removed from the ARS website although some establishments may have it downloaded on their computers. \u2022 This cooling model has not been validated, but may be used: ARS C. botulinum in beef broth cooling model (Available through PMP Online or the downloaded version of the ARS Pathogen Modeling Program). Although this model has not been validated, it is the best tool available at this time. Therefore, FSIS does not object to the use of this model without additional support.

2. Conduct modeling using at least five time-temperature data points. At least five data points are needed to run certain cooling models and to get an accurate estimate. If less than five data points are available, establishments may be able to develop a cooling curve by interpolating additional points, assuming a linear decrease between known values. One common error is incorrectly inputting time points using the wrong units; hours instead of minutes or minutes instead of hours.

3. Conduct modeling based on the worst-case cooling time-temperature profile for the product of interest. To assess what the worst-case cooling scenario might be, the establishment should account for its actual cooling CCP or prerequisite program critical limits. For example, if the establishment\u2019s,"66 customized cooling process schedule critical limits are to cool from 130\u00b0F to 80\u00b0F in 2 hours and between 80\u00b0F and 40\u00b0F in 5.5 hours, it should assume the worstcase (that is, a linear decrease) between these values in order to determine the growth of C. perfringens.

4. Input accurate pH and salt concentrations, if included in the model. Knowledge of intrinsic and extrinsic factors (e.g., pH, aw, temperature, salt concentration) used as inputs for the model is essential to have confidence in the results. Establishments should determine and use values for these parameters that represent the worst-case of possible processing conditions and have documentation to support the values used. If the establishment does not know the pH and salt concentrations, it should assume a worst-case pH of 6.2 and salt concentration of 1% unless no salt is added and then 0% should be used.

5. Maintain modeling results on file. Both the input and the output of the modeling results should be maintained as part of the supporting documentation for the life of the plan (9 CFR 417.5(a)(1)), along with support that the model has been validated (which could include this guideline).

**Validated Pathogen Models**

As described above, establishments should not rely on the results of a model alone unless the model has been validated for the particular food of interest. This section describes, in more detail, the sources for validated cooling models currently available for assessing the growth of C. perfringens in cooked\heat-treated meat and poultry products, with information on their availability. Not all models cover a full range of growth parameters. Therefore, knowledge of the basis for the model and its limitations in different food systems is key to making supportable determinations and using a model properly.", "67 ComBase Perfringens Predictor Model: The ComBase website contains a number of predictive microbial models. One in particular, The ComBase Perfringens Predictor model (see Figure 11) available at [https://browser.combase.cc/Perfringens\\_Predictor.aspx](https://browser.combase.cc/Perfringens_Predictor.aspx) has been validated<sup>11</sup> for cooked, cured, and uncured meat and poultry products. Therefore, establishments may rely on the results from this model alone. Establishments should be aware that this model provides an accurate estimation of the growth of C. perfringens in cooked, cured, and uncured meat and poultry products. Furthermore, in addition to taking into account whether the products are cured or uncured, the ComBase Perfringens Predictor model takes into account the pH and salt concentration of the meat or poultry product, which the other cooling models do not. Establishments may select the \u201ccured\u201d option for products

that contain at least 100 ppm of ingoing nitrite from a synthetic or natural source. USDA ARS Predictive Microbiology Information Portal (PMIP or PMP Online): The USDA ARS PMP Online, available at <https://pmp.errc.ars.usda.gov/PMPOnline.aspx>, contains a number of predictive microbial models (See Figure 12 for an example.).<sup>68</sup> A copy of the validation report is available from the Food Standard Agency, United Kingdom. The cooling model research has been published in the International Journal of Food Microbiology (Yvan Le Marc et al., 2008). Figure 11. Screenshot of ComBase Perfringens Predictor.<sup>69</sup> The following three cooling models for uncured meat and poultry products on PMP Online have been validated (Mohr et al., 2015): C. perfringens in cooked, uncured beef. C. perfringens in cooked, uncured pork. C. perfringens in cooked, uncured chicken. Establishments may, therefore, rely on the results from these cooling models alone, without any additional supporting documentation. In addition, the following models for cured meat and poultry products have been validated (Mohr, 2018): C. perfringens in cooked, cured beef. C. perfringens in cooked, cured pork. C. perfringens in cooked beef supplemented with NaCl, sodium nitrite, and sodium pyrophosphate. Establishments may, therefore, also rely on the results from these cooling models alone. Establishments should be aware that, in most cases, these cooling models will overestimate the amount of growth of C. perfringens in a meat or poultry product involved in a cooling deviation or for a customized cooling schedule. In addition, establishments should not rely solely on the results of other models within the PMP Online because most of them have not been validated. USDA ARS Pathogen Modeling Program (download version 7.0/8.0) The USDA's ARS has a number of predictive microbial models that are available in its downloadable Pathogen Modeling Program. The downloadable version of the Pathogen Modeling Program can be found at: <https://portal.errc.ars.usda.gov/PMP.aspx>. The following cooling models are available within the downloadable Pathogen Modeling Program (both version 7.0 and 8.0): C. perfringens in cooked, cured beef. C. perfringens in cooked, cured chicken. These cooling models have been validated (Mohr, 2018). Therefore, establishments may rely on the results from these cooling models alone. Figure 12. Screenshot of ARS PMP Online.<sup>70</sup> Establishments should be aware that in most cases these cooling models will overestimate the amount of growth of C. perfringens in a meat or poultry product involved in a cooling deviation or for a customized cooling schedule. In addition, establishments should not rely solely on the results of other models within the PMP Online since most of them have not been validated. Smith-Schaffner Model<sup>71</sup>: The Smith-Schaffner Model, Version 3, a Microsoft Excel-based model, is another cooling model that can be used for assessing the growth of C. perfringens. The Smith-Schaffner Model, Version 3, also meets the FSIS criteria for acceptable performance and validation for food safety<sup>72</sup> (Mohr et al., 2015). Therefore, establishments may rely on the results of this model alone. This model has been validated for cooked, uncured meat and poultry products. It is a reliable model for assessing the severity of cooling deviations for cooked, uncured meat and poultry products with typical pH values and typical levels of salt and phosphate. It is also a useful model for evaluating deviations because it allows for input of data where the temperature decreases and then increases and decreases a second time. The Smith-Schaffner Model is no longer available online but establishments may request a copy through askFSIS. Using Predictive Microbial Models to Assess Growth of Clostridia when a Process Incorporates Multiple Heat Treatments As previously explained, FSIS guidance is designed for cooling processes where the product is

cooked or heated once and then cooled. A full lethality treatment will destroy all vegetative cells of Clostridia, leaving only the spores to survive. It is the outgrowth of spores and the production of toxins or high levels of vegetative cells that are the concerns during stabilization. However, for some processes where the products are cooked, cooled, and then undergo a partial heat treatment followed by cooling, establishments should assess the cumulative growth of Clostridia. Establishments should take the following into account when determining whether they need to assess the growth of Clostridia over multiple heating and cooling steps:

- \u2022 If the process incorporates multiple full lethality treatments (i.e., by achieving FSIS Cooking Guideline conditions), the establishment needs to assess the growth of Clostridia during the cooling step following each individual lethality treatment and does not need to assess the cumulative growth over the multiple steps; and
- \u2022 If the process incorporates a full lethality treatment, and then is followed by a post-lethality heat treatment that does not achieve a full lethality and then restabilizes (cools) the product, the establishment should assess the cumulative growth of *C. perfringens* that occurs during the first cooling process, the growth,"70 that occurs during the heating come-up, and the growth that occurs during the cooling come-down time of the subsequent post-lethality treatment or warming step. Common examples of processes that use post lethality heat treatments include double smoking, applying heat to the surface of a cooled RTE product after slicing, reheating a filling, or frying a tamale that contains cooked meat. To assess the cumulative growth of *C. perfringens* in the process, as described in the second bullet above, establishments should perform predictive microbial modeling of certain heating and cooling steps in the process. More specifically, this modeling should include the first cooling step and the heating come-up and cooling come-down time of the subsequent post-lethality treatment or warming step using the same model. FSIS recommends that to perform the modeling, establishments collect time-temperature profiles for each of the aforementioned heating and cooling steps. Establishments that receive previously cooked product from a supplier and then apply a heat treatment should communicate with their supplier to obtain its worst-case cooling profile or its cooling critical limits\prerequisite program limits to determine the worst-case cooling profile (e.g., by interpolating additional points for modeling by assuming a linear decrease between time-temperature limits). Based on the worst-case time-temperature profiles, establishments can use one of the options below for modeling cooked meat and poultry products:

1. Use the ComBase Perfringens Predictor cooling model (found under Food Models on the ComBase website) and the ComBase *C. perfringens* Growth Model (found under Growth Models on the ComBase website) to assess the cumulative growth of *C. perfringens* during the entire time-temperature profile based upon a worst-case scenario approach. For this option, FSIS recommends that establishments:
  - \u2022 Use the ComBase Perfringens Predictor to estimate the *C. perfringens* growth during the first cooling step and then add those results to the results obtained by performing the next step below.
  - \u2022 Use the ComBase *C. perfringens* Growth Model to estimate the *C. perfringens* growth during the heating come-up and cooling come-down time of the subsequent post-lethality treatment or warming step.
  - o Use a physiological state of 1 (no lag phase) to model in a conservative manner, given that many of these predictive microbial growth models are not fail-safe for predicting the lag phase (Tamplin, 2002; Vold, et al., 2000; Walls and Scott, 1996).
  - o Use a temperature of 59\u00b0F (15\u00b0C) for the product\u2019s time-temperature data points that are below 59\u00b0F (15\u00b0C) to

overcome one of the shortcomings of using the ComBase C. perfringens growth model. NOTE: It is only appropriate to conduct separate models for each of the steps in the process (e.g., modeling the first cooling step and then the second heating CUT and cooling step separately) if a physiological state of 1 is used to indicate no lag phase, when using the ComBase C. perfringens Growth Model. Otherwise, the modeling would assume C. perfringens undergoes a lag phase,"71 each time the model is run, which would not be representative of the actual process. 2. Use the ComBase C. perfringens Growth Model to assess the cumulative growth of C. perfringens during the entire time-temperature profile based upon a worst-case scenario approach. For this option, FSIS recommends that establishments: \u2022 Use a physiological state of 1 to model, in a conservative manner, especially given that many of these predictive microbial growth models are not fail-safe for predicting the lag phase (Tamplin, 2002; Vold, et al., 2000; Walls and Scott, 1996); and \u2022 Use a temperature of 59\u00b0F (15\u00b0C) for product\u2019s time-temperature data points that are below 59\u00b0F (15\u00b0C) to overcome one of the shortcomings of using the ComBase C. perfringens growth model. 3. Use the Smith-Schaffner Model to assess the cumulative growth of C. perfringens during the entire time-temperature profile based upon a worst-case scenario approach. The modeling results should demonstrate that the entire process allows no more than the performance standard or the target the establishment identifies (i.e., 1.0-Log total growth of C. perfringens and no multiplication of C. botulinum) in the finished product before shipment. When employing a post-lethality heat treatment, establishments should remember that C. perfringens will not grow at temperatures of 130\u00b0F or greater. Establishments may also choose to conduct a challenge study to demonstrate that the entire process allows no more than the performance standard or the target the establishment identifies (i.e., 1.0-Log total growth of C. perfringens and no multiplication of C. botulinum) in the finished product before shipment.

**Corrective Actions to Perform When a Cooling Deviation Occurs**

Cooling deviations occur when an establishment fails to meet its cooling CCP critical limit or cooling process schedule. Common causes for cooling deviations are exceeding the chilling capacity of the coolers, power failures, or breakdowns of refrigeration equipment. Establishments are required to take corrective actions, as per the HACCP regulations, regardless of whether the cooling process is addressed through a CCP or prerequisite program. In such situations, establishments must be able to ensure that no product that is injurious to health or otherwise adulterated because of the deviation enters commerce, and to support its product disposition decisions (9 CFR 417.3(a) and (b)). NOTE: FSIS included the Corrective Actions to Perform When a Cooling Deviation Occurs within the Pathogen Modeling section because FSIS recommends pathogen modeling as the first step to evaluate product safety. FSIS does not recommend testing without modeling first."72 When cooling is addressed through a CCP, establishments are required to determine the cause of all cooling deviations, no matter how small (9 CFR 417.3(a)(1)), and ensure measures are established to prevent recurrence (9 CFR 417.3(a)(3)). Ultimately, if the cause of each small cooling deviation is not traced and corrected when first noticed, the problem will likely recur and become more frequent and more severe. The establishment should consider an occasional small deviation to be an opportunity to find and correct a problem. Large deviations or continual small ones always constitute unacceptable risk. Also, continual or repetitive deviations from the critical limit demonstrate that the establishment is unable to control its process and that corrective actions are not preventing problems as intended (9 CFR 417.4(b)).

When cooling is addressed through a prerequisite program and a deviation occurs, establishments are required to reassess their food safety system to determine whether the newly identified deviation or unforeseen hazard should be addressed and incorporated into the HACCP plan (9 CFR 417.3(b)(4)). Also, an establishment may not be able to continue to support the decision in its hazard analysis that spore-formers are not reasonably likely to occur, if it has continual or repetitive deviations from its cooling prerequisite program (9 CFR 417.5(a)(1)). To determine the safety of the product affected by a cooling deviation, FSIS recommends that establishments first conduct modeling using validated cooling models. Depending on the results of the modeling, sampling may be recommended. As part of the support for product safety, FSIS recommends establishments write up an assessment of the deviation that addresses the specific hazards and includes: \u2022 The predictive microbial model selected (including supporting documentation that the model has been validated). \u2022 The data inputs to the model (and in the case of missing data, a rationale or support for data used). \u2022 An assessment of the results generated by the model. \u2022 A product disposition determination." "73 Using Pathogen Modeling to Assess a Cooling Deviation FSIS recommends establishments use validated predictive microbial models to assess cooling deviations, such as the ComBase Perfringens Predictor model. General recommendations regarding cooling models can be found on page 64 of this guideline. Predictive microbial models (i.e., cooling models) are an excellent tool to use in assessing the severity of a cooling deviation, provided the model has been validated for the specific product. In the case of a cooling deviation, establishments should input the time-temperature profile as documented through monitoring. If an establishment does not know the pH or salt concentration of the product that experienced the cooling deviation, it should assume a worst-case pH of 6.2 and a salt concentration of 1% (Mohr et al., 2015). Once establishments obtain modeling results, they should evaluate them to determine product disposition. The disposition of RTE and NRTE product resulting from cooling deviations and based on modeling and\or sampling should follow the criteria below: \u2022 Result 1. There is no more than 1-Log growth of *C. perfringens* and no *C. botulinum* growth (mean net growth \u2264 0.30-Log)<sup>12</sup> then the process meets the stabilization performance standard or policy and the product may be: o Released into commerce. \u2022 Result 2. There is more than a 1-Log growth of *C. perfringens*, no *C. botulinum* growth<sup>13</sup> (mean net growth \u2264 0.30-Log), less than 3.0-Log growth of *B. cereus*<sup>14</sup>, and the establishment does not have support that spore levels in the product are low, then product may be: o Recooked, o Sampled and Tested (N \u2265 10), or 12If there is no more than 1-Log growth of *C. perfringens*, then multiplication of *C. botulinum* is unlikely based on FSIS\u2019s review of modeling that establishments conducted in response to deviations and FSIS\u2019 modeling performed to support its cooling recommendations. Therefore, establishments can support the products\u2019 safety using *C. perfringens* alone without conducting modeling for *C. botulinum*. <sup>13</sup>In the event of a cooling deviation for cured meat and poultry products, establishments can support the safety of affected product using modeling for *C. perfringens* alone without conducting modeling for *C. botulinum* because the presence of nitrite, salt, and a cure accelerator such as sodium erythorbate, should ensure that no multiplication of *C. botulinum* occurred during the deviation <sup>14</sup>In general, establishments only need to assess *B. cereus* growth when modeling estimates *C. perfringens* growth is \u02c3 3.0-Log\u2014because *C. perfringens* grows faster than *B. cereus*. Establishments can assess *B.*

cereus growth using the ComBase Growth Model for *B. cereus* (found under ComBase Predictor Growth Models). Although this model has not been validated, it is the best tool available, so establishments may use it. Establishments should use a physiological state of 1 to model in a conservative manner, especially given that many of these predictive microbial growth models are not failsafe for predicting the lag phase.","74 o Destroy the product (rendered or denatured per 9 CFR 314.3(a), 9 CFR 325.11(a), 9 CFR 325.13(a)(1) through 325.13(a)(7), or 9 CFR 381.95 and sent to a landfill). \u2022 Result 3. There is greater than a 1.0-Log growth of *C. perfringens* and greater than a 0.30-Log increase of *C. botulinum*, then product must be: o Destroy the product (rendered or denatured per 9 CFR 314.3(a), 9 CFR 325.11(a), 9 CFR 325.13(a)(1) through 325.13(a)(7), or 9 CFR 381.95 and sent to a landfill). Sampling after Pathogen Modeling If an establishment has conducted modeling that showed Result 2 above, then the establishment may conduct sampling to assess the safety of the product involved in a deviation. FSIS recommends that establishments conduct modeling prior to any sampling, because it provides greater confidence for estimating levels of *C. perfringens* growth. Sampling is more limited because *C. perfringens* is generally not evenly distributed throughout the product. Therefore, depending on the results of the modeling, sampling may be an appropriate tool to provide information to the establishment to help support product disposition. Specifically, if modeling indicates there is more than a 1-Log growth of *C. perfringens* and no *C. botulinum* growth (mean net growth \u2264 0.3-Log), less than 3-Log growth of *B. cereus*, and the establishment does not have support that spore levels in the product are low, then product may be sampled to further support product safety. The following are FSIS recommendations for conducting this sampling and testing: \u2022 At least 10 samples per affected lot should be taken at random. Samples should NOT be composited because the analysis is quantitative for each sample to determine product disposition. \u2022 Samples should be refrigerated at 2-10\u00b0C (35-50\u00b0F) immediately after collection. Samples should be shipped to the laboratory under refrigerated (2-10\u00b0C) conditions overnight or for receipt within 24 hours at the laboratory. Upon laboratory receipt, samples should be inspected for condition and temperature and immediately refrigerated (2-10\u00b0C). The laboratory should promptly analyze samples to avoid loss of cell viability. The laboratory should not analyze samples more than 24 hours after receipt or that have been compromised during shipping. \u2022 Testing should be performed to specifically assess for *C. perfringens* or gas forming anaerobes (GFAs). FSIS considers modeling results that demonstrate > 0.30-Log increase of *C. botulinum* to indicate multiplication. In general, predictive models FSIS recommends, such as the ARS *C. botulinum* in beef broth model, do not predict zero growth. As a practical way to evaluate cooling deviations, the Agency has regarded a predicted growth of no more than 0.3-Log (an approximate doubling, or one generation) as an indication that there has been no growth.","75 \u2022 If no sample exceeds 100 CFU/gram and no more than two samples equal 100 CFU/gram, then the lot can be released into commerce and sold as is. If no more than two samples exceed 100 CFU/gram and none exceeds 500 CFU/gram, then establishments should recook the lot of product. If more than two samples equal or exceed 100 CFU/gram or any exceed 500 CFU/gram, then the product should be destroyed. Recooking after Pathogen Modeling If an establishment has conducted modeling that showed Result 2 above, then the establishment also has the option to recook the product (without sampling and testing). FSIS recommends establishments conduct predictive microbial modeling for *C. botulinum* before

recooking, because in the event the modeling shows greater than a 0.3-Log increase of C. botulinum, then recooking is not an appropriate method of product disposition. A minimum recock temperature of 149°F with a holding time of at least two minutes, or a minimum instantaneous temperature of 169°F, is recommended when recocking product. This will address the hazard of C. perfringens vegetative cells because it will result in at least a 5.0-Log reduction. FSIS recommends establishments recock only when: (1) All product was either immediately refrigerated after the deviation or can be immediately recooked after the deviation. (2) The recocking procedure can achieve a final internal product temperature of at least 149°F (65°C) for two (2) minutes or an instantaneous internal product temperature of 169°F. Subsequent to recocking, the product must again be cooled according to the establishment's support. (3) When the product is to be reworked with another raw product, the recocking procedure for the combined product must achieve a minimum internal product temperature of 149°F (2 minutes holding time) to address the cooling deviation. The time-temperature for the combined product should be increased further, if necessary, to be in accord with any other requirement relative to microbiological safety for the intended final product. The reworked product must again be cooled to meet these same stabilization performance standards or targets. FSIS recommends establishments recock product to a final internal product temperature of at least 149°F (65°C) for two (2) minutes or an instantaneous internal product temperature of 169°F, because C. perfringens is more heat tolerant once a product has been cooked. The time-temperature options in the FSIS Cooking Guideline meat table are based on thermal death time studies for Salmonella in raw ground beef. Therefore, the recommendations may not be sufficient to address C. perfringens in a cooked product. For example, Vijay et al., 1998 showed that contaminated cooked beef should be re-heated to an internal temperature of 62.5°C (144.5°F) for at least 9.6 minutes and cooked turkey for at least 7.8 minutes to achieve at least a 6-Log, 76 reduction of C. perfringens. However, the FSIS Cooking Guideline time-temperature table for meat products only has a dwell time of 5 minutes at 62.2°C (144°F). FSIS's recocking recommendations are based on D- and z-values reported in the published research (Vijay et al., 1998). FSIS defined instantaneous temperature based on a dwell time of 10 seconds. Establishments may recock to other temperatures, provided they can support that the procedure would result in at least a 5.0-Log reduction of C. perfringens in a product that has been cooked. These values may not be suitable if the product to be recocked underwent a drying process after the original cooking step. (77 Attachment B6. Other Published Processing Guidelines for Cooling FDA Time-Temperature Recommendations for Cooling The Food and Drug Administration (FDA) Food Code is another type of support that establishments may use for cooling. Section 3-501.14 Cooling of the 2017 FDA Food Code recommends the following parameters for cooling products cooked to full lethality: (A) Cooked TIME/TEMPERATURE CONTROL FOR SAFETY FOOD shall be cooled: (1) Within 2 hours from 57°C (135°F) to 21°C (70°F); and (2) Within a total of 6 hours from 57°C (135°F) to 5°C (41°F) or less. This option applies to: 1. Products cooked to full lethality (including intact or non-intact meat or poultry). Establishments must keep the most up-to-date copy of the FDA Food Code on file as supporting documentation to use this cooling procedure. CFIA Time-Temperature Recommendations for Cooling An establishment may follow the cooling parameters from the Canadian Food Inspection Agency

(CFIA) cooling procedure found in the CFIA\u2019s Cooling of Heat Processed Meat Products, because FSIS has verified this option results in \u2264 1 log growth of *C. perfringens* and no multiplication of *C. botulinum*. During continuous cooling immediately after the heating cycle is completed: (A) The product's maximum internal temperature must not remain between 54\u00b0C (129.2\u00b0F) and 27\u00b0C (80.6\u00b0F) for more than two (2) hours, and (B) Not remain between 54\u00b0C (129.2\u00b0F) and 4\u00b0C (39.2\u00b0F) for more than 7 hours." , "78 Attachment B7. Using Challenge Studies to Support Alternative

Stabilization\Cooling Procedures In cases where an establishment\u2019s process does not match available scientific support documents, such as this guideline or a published journal article, establishments may decide to conduct an inoculation challenge study to support that their process achieves adequate cooling and controls the growth of Clostridia. In a challenge study, the number of organisms before and after the application of the control measure are counted to determine the effect of the control measure. Challenge studies should be conducted by a microbiologist trained in performing challenge studies in a laboratory to avoid the possible spread of contamination in an establishment. The challenge study should be designed to match the establishment\u2019s time-temperature cooling profiles and intrinsic factors in the establishment\u2019s actual process in order to establish these as critical operating parameters. It is also important for the challenge study to be conducted using the pathogen of interest and that the appropriate inoculation level be 1 to 3-Log CFU\g to show limited Log growth of the target pathogens. *C. perfringens* can be used alone in an inoculated pack study to demonstrate that the cooling performance standard or target is met for both *C. perfringens* and *C. botulinum*. This is because conditions of time-temperature that would limit the growth of *C. perfringens* to 1-Log or less would also prevent multiplication of *C. botulinum*, which is much slower. A cocktail of various strains of *C. perfringens* spores is often used for this purpose.

Relatively \"fast\" growing toxigenic strains of *C. perfringens* should be used to develop a worst-case scenario. However, the spore strains selected should also be heat-tolerant and among those that have been historically implicated in an appreciable number of outbreaks, especially in products similar to those being prepared by the establishment. In consultation with ARS, FSIS recommends establishments use a cocktail of the following three strains of *C. perfringens*: NCTC 8238 (Hobbs serotype 2), NCTC 8239 (Hobbs serotype 3) and NCTC 10240 (Hobbs serotype 13). The final measure of bacterial load in the product after cooling should include a measure of both spore levels and vegetative cells. Challenge studies should contain an equivalent level of detail as peer-reviewed scientific literature and should use methodology equivalent to that used in peerreviewed research. As stated in the FSIS Validation Guideline, page 8, challenge studies should be based on a sound statistical design (i.e., a statistical design that ensures confidence in the data) and should employ positive and negative controls. The statistical design should include the number of samples collected at each time interval and the number of study replicates needed to ensure the validity of the study. There are quantitative methods for assessing the statistical quality of a study (e.g., power analysis). As recommended by the National Advisory Committee on Microbiological Criteria of Foods (NACMCF), the minimum number of samples to be analyzed initially and at each time interval during processing or storage should be at least two; however, NACMCF recommends analysis of three or more samples. According to NACMCF, replicates should also be conducted. Replicates should be independent trials using different lots of product and inoculum to account for variations in

product, process, inoculum, and other factors. When the number of samples analyzed at each time interval is only two, it is better for the study to be repeated (replicated) more than two","79 times. In studies with three or more samples tested at each time interval, two replicates are usually adequate. All the critical elements of the study discussed above need to be included to permit evaluation or confirmation of the results. For more information on conducting challenge studies please review the article, \u201cParameters for Determining Inoculated Pack\Challenge Study Protocols\u201d published by the NACMCF in the Journal of Food Protection in 2010.", "80 Attachment B8. Using Journal Articles to Support Alternative Stabilization or Cooling Procedures Establishments may use published journal articles as scientific support for their process as they are a type of peer-reviewed scientific data discussed in the FSIS Validation Guideline. If an establishment chooses to use a journal article as scientific support, it should ensure that all critical operating parameters used in the study match those used in the actual process. Examples of critical operational parameters that should be compared include cooling time-temperature profile, amenable species of meat or poultry used in the product, pH, water activity, salt concentration, sodium nitrite concentration, and any added antimicrobial ingredients. Some of these critical operational parameters may become part of the critical limits of a CCP, may be incorporated into a prerequisite program or may be monitored at the set-up of the food safety system as part of initial validation. If one or more of the critical operating parameters are not addressed in the establishment\u2019s process or do not match the parameters used in the support, then the establishment should document a science-based justification for why the parameter does not need to be met or measured, or why it differs from the support. Additionally, an establishment should have knowledge of the products it produces, including knowledge of the pH, salt concentration, etc. even if these are not critical operating parameters in its scientific support because this information can be helpful in the event of a cooling deviation. FSIS has compiled a summary table of journal articles that establishments may use as scientific support for their process in Table 15 (page 82). In response to common questions, FSIS has included in this table articles for the stabilization of partially heat-treated bacon and fully cooked scrapple (Table 15). FSIS has also provided recommendations for using published research on bacon heating CUT along with predictive microbial modeling to support stabilization of bacon processes (page 81). Table 15 is only to be used as a quick reference guide so an establishment can identify a similar product and process. This table is not valid support for a HACCP system. Rather, establishments should maintain a copy of any articles it uses for scientific support of their systems.", "81 Alternative support for partially heat-treated bacon FSIS is also aware of a study by Sindelar et al. (2019) evaluating C. perfringens growth during slow partial heat treatment of pork instead of smoked pork bellies. This article was not included in the summary table (Table 15) since it does not address C. perfringens growth during stabilization (cooling). However, establishments may consider using this article and predictive microbial modeling to support a custom cooling schedule for partially heat-treated bacon products with long CUT. To do this, the establishment would: 1. Follow the heating process schedule from the article (Sindelar et al., 2019), address all critical operating parameters, and maintain a copy of the article on file. 2. Use predictive microbial modeling to develop a custom cooling schedule that limits the growth of C. perfringens during cooling to 0.3-Log or less. To model the cooling, FSIS recommends using the ComBase C. perfringens Growth Model based upon a worst-case scenario approach. When performing modeling, FSIS

recommends that establishments:

- o Use a physiological state of 1 (no lag phase) to model in a conservative manner, since Sindelar et al. (2019) showed the bacteria will be out of the lag phase as the product starts to cool;
- o Use a temperature of 59\u00b0F (15\u00b0C) for product\u2019s time-temperature data points that are below 59\u00b0F (15\u00b0C) to overcome one of the shortcomings of using the ComBase C. perfringens Growth Model.

3. Maintain a copy of the custom modeling support on file (see Attachment B5. Predictive Microbial Modeling, page 64).

4. Maintain a decision-making document or a copy of this guidance to explain how the two scientific documents may be combined to address cumulative C. perfringens growth

- o Specifically, the Sindelar et al. (2019) estimated that 0.7-Log C. perfringens growth during the heating CUT, plus \u22640.3-Log growth during the custom cooling schedule, will ensure that total C. perfringens growth during heating and cooling of the bacon is limited to 1.0-Log or less.", "This Appendix is not considered adequate support on its own because it does not provide the details of each study (such as the concentration of salt and other ingredients) that an establishment needs to determine if the study is representative of the actual process. Establishments need to have the complete copy of the article on file as part of its supporting documentation to determine the levels of the critical operating parameters used.

FSIS recommends establishments assume the longer cooling time would result in the same amount of growth if not higher than the shorter time. 23 Establishments should be aware that the 18-hour treatment time had less growth than the 15-hour treatment time. FSIS recommends establishments assume the longer cooling time would result in the same amount of growth if not higher than the shorter time.", "92 Journal Articles not Acceptable without Further Support The table above summarizes journal articles that may be used as support. The following three articles are not acceptable as support because FSIS has identified methodological errors or flaws in the research or reporting: \u2022 Haneklaus A.N., Harris K.B., Cuervo M.P., Ilhak O.I., Lucia L.M., Castillo A., Hardin M.D., Osburn W.N., and Savell, J.W. 2011. Alternative Cooling Procedures for Large, Intact Meat Products to Achieve Stabilization Microbiological Performance Standards. Journal of Food Protection. Vol. 74: 101105. \u2022 Juneja, V.K., Snyder, O.P., and Cygnarowicz-Provost, M. 1994. Influence of Cooling Rate on Outgrowth of Clostridium perfringens Spores in Cooked Ground Beef. Journal of Food Protection. 57: 1063-1067. \u2022 Steele, F.M. and Wright K.H. 2001. Cooling Rate Effect on Outgrowth of Clostridium perfringens in Cooked, Ready-to-Eat Turkey Breast Roasts. Poultry Science. 80: 813-816. FSIS does not recommend establishments use these three articles alone because of the methodological errors identified, without additional support. If an establishment chooses to use one of these articles as support for its stabilization process, FSIS recommends the establishment gather additional data (e.g., microbiological data gathered in-plant or an inoculation challenge study) to address the concerns outlined below. The following information explains the methodology errors or flaws that FSIS has identified in each of the three articles of concern. Alternative Cooling Procedures for Large, Intact Meat Products to Achieve Stabilization Microbiological Performance Standards (Haneklaus et al., 2011) FSIS does not recommend establishments use this article alone based on the method the authors used to measure bacterial load in the final product. In this article, C. perfringens spore counts were used to measure bacterial load in the final product and to determine product safety. Although measuring C. perfringens spore counts is considered an appropriate method to quantify the initial levels of the C. perfringens inoculum, the final measure of bacterial load should include a measure of both spore levels and vegetative cells. FSIS recommends establishments measure the vegetative cells in addition to the spore levels, because during stabilization, C. perfringens

spores can germinate and grow into vegetative cells. Once vegetative cells reach a critical level, and the contaminated food is consumed, some of the cells will survive passage in the stomach and produce toxin during sporulation in the intestines to cause illness. Several published studies (Juneja, Thippareddi, and Friedman, 2006; Juneja, Bari, Inatsu, Kawamoto, and Friedman, 2007; Sabah, Juneja, and Fung, 2004; Sanchez-Plata, Amador-Quita, Blankenship, Burson, Juneja, and Thippareddi, 2005; Velugoti, "93 Rajagopal, Juneja, and Thippareddi, 2007) have used similar stabilization parameters to that used in the Haneklaus et al. (2011) article [i.e., cooled from 129.9°F (54.4°C) to 45°F (7.2°C) in 9, 12, or 15 hours] to measure total *C. perfringens* growth in cooked, uncured pork and beef products that are exponentially cooled. These studies have shown that, when these processes are used, significant growth (>1 Log increase) of *C. perfringens* will occur. The amount of total *C. perfringens* growth ranged from 1.72 to 5.37-Log depending on the experiment and the product's intrinsic factors (e.g., pH, percent salt, and percent phosphate) (Juneja et al., 2006; Juneja et al., 2007; Sabah et al., 2004; Sanchez-Plata et al., 2005; Velugoti et al., 2007). FSIS believes these studies accurately represent the combined vegetative and spore load of *C. perfringens* present in products that are exposed to stabilization parameters that are similar to those used in the Haneklaus, et al. (2011) study. When the published studies use shorter stabilization parameters [i.e., cooled from 129.9°F (54.4°C) to 45°F (7.3°C) in 6.5 hours], lower levels of growth of *C. perfringens* (1 Log increase) are observed, which is consistent with FSIS guidance in Option 1.1 of this guideline.

Influence of Cooling Rate on Outgrowth of *C. perfringens* Spores in Cooked Ground Beef (Juneja et al., 1994)

FSIS does not recommend establishments use this article alone based on the methods the authors used in which ground beef was packaged in Whirlpak bags as opposed to Spiral Biotech pouches, which are more commonly used in these types of studies. Juneja et al. (1994) study used the Whirlpak bags and demonstrated minimal growth of *C. perfringens* in cooked ground beef for cooling periods up to 15 hours that were supposed to represent anaerobic conditions. Subsequent research conducted by Smith et al. (2004) demonstrated that ground beef packaged in Whirlpak bags shows significantly less growth of *C. perfringens* than ground beef packaged in Spiral Biotech bags (Smith et al., 2004). This is probably due to the Whirlpak bag's greater oxygen permeability. For example, more than a 5-Log increase in *C. perfringens* was seen in ground beef contained within Spiral Biotech pouches compared with only a 0.81 to 2.05 Log increase in samples within WhirlPak bags during a 21-hour cooling cycle. Smith et al. (2004) concluded that the study demonstrates that the use of Whirlpak bags is unsuitable for use in challenge studies, because of the bags apparent high oxygen permeability, which probably suppresses or slows the growth of the anaerobe *C. perfringens*. Several published studies support that similar cooling profiles result in significant growth (> 1 Log increase) of *C. perfringens* in cooked beef products that are non-linearly cooled from 130°F (54.4°C) to 45°F (7.2°C) in 15 hours. The amount of *C. perfringens* growth ranged from 1.72 to 5.37-Log depending on the experiment and the product's intrinsic factors (e.g., pH, percent salt, and percent phosphate) (Juneja et al., 2006; Sabah et al., 2004; Smith et al., 2004; Zaika, 2003). Furthermore, the same studies showed that non-linear chilling from 54.4 to 7.2°C in 12 or 9 hours also resulted in more than 1 Log increase in *C. perfringens* (Juneja et al., 2006; Sabah et al., 2004; Zaika, 2003). Consequently, these more recently published studies contradict the 1994 Juneja study that

showed no growth of *C. perfringens* in cooked ground beef cooled from 54.4°C to 7.2°C during a 15-hour cooling period." "94 Cooling Rate Effect on Outgrowth of *C. perfringens* in Cooked, Ready-to-Eat Turkey Breast Roasts (Steele and Wright, 2001) FSIS does not recommend establishments use this article alone because the paper included inadequate information to allow comparison to an establishment's actual process. Published research and predictive microbial models have shown that the product's intrinsic factors (e.g., pH, sodium nitrite, salt, and phosphate concentration) can have a profound impact on the growth of *C. perfringens* during cooling, or temperature abuse of cooked/heated, not shelf-stable meat and poultry products. For example, research has shown that a high salt concentration can have a significant inhibitory effect on the growth of *C. perfringens* during cooling (Zaika, 2003). However, information on the product's intrinsic factors was not included in the article. Therefore, it would not be possible for establishments to assess how their products compare to the product(s) studied." "95 <https://www.fsis.usda.gov/contact-us/askfsis> FSIS USDA www.fsis.usda.gov

Country-Cured Hams ..... 90", "4 Preface This is a revised version of the FSIS Cooking Guideline for Meat and Poultry Products (Revised Appendix A). It has been updated in response to comments received on the previous version and renamed. In addition, the guideline has been revised to include recommendations from previous versions and new updates based on up-to-date science. The guideline also includes changes to improve its readability. This guideline represents FSIS\u2019s current thinking on these topics.

Establishments that utilized previous versions of Appendix A as support should either: \u2022 Update to this 2021 FSIS Cooking Guideline (Revised Appendix A) or \u2022 Identify alternative support by December 14, 2022. The information in this guideline is provided to assist meat and poultry establishments in meeting the regulatory requirements. The contents of this document do not have the force and effect of law and are not meant to bind the public in any way. This document is intended only to provide clarity to industry regarding existing requirements under the regulations. Under the regulations, meat and poultry establishments may choose to implement different procedures than those outlined in this guideline, but they would need to validate and support how those procedures are effective. This guideline is focused on small and very small plants in support of the Small Business Administration\u2019s initiative to provide small businesses with compliance assistance under the Small Business Regulatory Enforcement Fairness Act (SBREFA). However, all meat and poultry establishments may apply the recommendations in this guideline. It is important that small and very small establishments have access to a full range of scientific and technical support, and the assistance needed to establish safe and effective Hazards Analysis and Critical Control Point (HACCP) systems.

Although large plants can benefit from the information, focusing the guideline on the needs of small and very small establishments provides them with assistance that may be otherwise unavailable to them. Purpose of this Guideline This guideline contains information to assist meat and poultry establishments producing products that undergo cooking in complying with the HACCP regulatory requirements in 9 CFR 417. This guideline includes information on:

\u2022 Biological hazards during cooking. \u2022 Regulatory requirements associated with the safe production of cooked ready-to-eat (RTE) products. \u2022 Options establishments can use to achieve lethality of Salmonella and other pathogens.", "5 \u2022 Processes that do not have validated research available (referred to as \u201ccientific gaps\u201d) and options establishments can use until research is available. \u2022 Resources for alternative support.

\u2022 Recommendations for evaluating cooking deviations. Establishments can always seek guidance from State university extension service specialists and HACCP Coordinators on developing programs and plans not provided in this guideline to comply with HACCP regulatory requirements. History of this Guideline and Reason for Reissuance In the 1970s and 1980s, FSIS included prescriptive time, temperature, and humidity operating parameters in the regulations for cooked beef, roast beef, and cooked corned beef (42 FR 44217; 47 FR 31854; 48 FR 24314) in response to several outbreaks associated with these products and research performed to determine how to prepare them safely. When the Pathogen Reduction/Hazard Analysis and Critical Control Points (PR/HACCP) final rule published in 1996, FSIS eliminated the prescriptive cooking regulations and replaced them with performance standards requiring a 6.5-Log reduction in Salmonella or alternative lethality for roast beef, cooked beef, and corned beef, minimum internal temperature and holding times for fully cooked patties that achieve a 5-Log reduction in Salmonella, and a 7-Log reduction in Salmonella or alternative lethality for poultry

products (9 CFR 318.17(a)(1), 9 CFR 318.23, 9 CFR 381.150(a)(1); see General Considerations for Designing HACCP Systems to Achieve Lethality by Cooking, page 18. FSIS converted these former regulations to \u201cSafe Harbors\u201d in an appendix to the final rule called Appendix A (64 FR 732). Establishments have been using FSIS\u2019s Appendix A, as published in 1999, as support for cooking processes for many years. The original requirements and subsequent guidance have been important to prevent human illness outbreaks and ensure the production of safe food. See General Considerations for Designing HACCP Systems to Achieve Lethality by Cooking, page 18 for more information on the current regulatory requirements. Over time, FSIS determined that some of its recommendations in the 1999 version of Appendix A were vague, putting establishments at risk of producing unsafe products. Additionally, some elements of the 1999 version of Appendix A were misunderstood or overlooked, resulting in FSIS guidance being applied in ways that increased food safety risks to consumers and potential risks to industry, including the risk of foodborne illness outbreaks. FSIS also determined establishments were broadly applying the recommendations for operating parameters in Appendix A beyond those meat and poultry products it was originally designed to support. To provide the needed updates and clarifications, FSIS issued revisions of both its Cooking (Appendix A) and Stabilization (Appendix B) guidelines in 2017. The 2017 version of the guidelines took into account new and emerging technologies, processes, and science. FSIS has updated this guideline in response to comments received on the 2017 version and has included additional options for cooking support based on updated", "6 science and technology. The Agency is releasing this current 2021 version of the FSIS Cooking Guideline for Meat and Poultry Products (Revised Appendix A) to replace all previous versions. Changes from the Previous Versions This guideline dated December 14, 2021 is final. FSIS will update this guideline, as necessary, should new information become available. FSIS made the following changes to this guideline to reflect the comments received on the previous version during the comment period and to include additional scientific information. For Appendix A, FSIS made changes to specify: \u2022 The following products are not covered by the guideline (page 11): Fish of the Order Siluriformes, pork rind pellets, rendered lard and tallow, dried products processed under dry conditions, partially heat-treated NRTE products, and RTE multi-hurdle products. \u2022 The food safety significance of FSIS\u2019s recommendations for relative humidity (page 17). \u2022 That relative humidity should be addressed for all cooked products (including poultry) unless the establishment can support that humidity does not need to be addressed. FSIS has not changed the relative humidity options (page 26) other than re-emphasizing that they apply to all products. \u2022 Additional resources for selecting a relative humidity option when following FSIS\u2019s cooking guidance (page 28). \u2022 The situations when relative humidity does not need to be addressed including by providing more information about situations considered to be direct heating (page 31) (e.g., by clarifying that relative humidity does not need to be addressed for meat patties cooked using FSIS\u2019s time-temperature table for meat, if the patties are cooked using direct heat (on page 31)). Previous guidance indicated it did not need to be addressed for meat patties with the assumption all meat patties are cooked using direct heat which is no longer the case. \u2022 That natural casings become semipermeable during cooking, maintaining moisture in the product, so that additional documentation to address relative humidity is not needed (page 33). \u2022 More detailed information for evaluating product safety following a heating deviation (page 66). The revision

also removes the recommendation for using the ComBase model for *Staphylococcus aureus* growth (which was not validated)", "7 because of the development and validation of the Danish Meat Research Institute (DMRI) Staphtox model in 2018. \u2022 Where gaps exist, recommendations from its older cooking guidance can be used until research is completed (see, Table 5. Scientific Gaps where Critical Operating Parameters From Older Guidance May be Used, page 43) for: 1. Products cooked for short times at high temperatures. 2. Products cooked using microwave cooking methods that are not designed to control relative humidity. 3. Products cooked using cooking methods that are not designed to control relative humidity. 4. Other processes that may inherently maintain relative humidity around the meat and poultry filling but cannot follow one of the relative humidity options. 5. Processes where the drying step comes before cooking under moist conditions. 6. Products with long heating come-up-times (CUTs). \u2022 That information is included about a listeriosis outbreak associated with a cooked country-cured ham product and recommendations for establishments that cook a similar product once (page 90). For Appendix A, FSIS removed: \u2022 Information about how establishments could remove poultry rolls from the cooking medium before product has achieved the target endpoint temperature and immediately apply another heating or processing method (64 FR 732). Since FSIS has clarified that limiting heating CUT is a critical operating parameter for applying any of FSIS cooking guidance (including these older options), the parameter to \u201cimmediately fully cook\u201d poultry rolls subject to multiple heating mediums and processes has been removed. \u2022 Specific recommendations for conducting a *Salmonella* baseline study on raw source materials as support for using cooking critical operating parameters that achieve a 5-Log reduction in *Salmonella* for meat products instead of a 6.5 or 7Log reduction. This information was removed since it was interpreted to apply to all establishments when it was only intended for establishments that wanted to support a lower level of pathogen reduction from cooking. In addition, FSIS is not aware of any establishments that have pursued such baseline sampling. In addition to these changes, the guidelines format was restructured to make it easier to use as described in the next section. This list of changes is not comprehensive, so", "8 establishments should read the section titled FSIS Critical Operating Parameters for Cooking and other relevant sections as needed. How to Effectively Use this Guideline As explained above in the Changes from the Previous Versions, the guidelines format was restructured to make it easier to use. Specifically, the guideline is organized to include the following topics in the body of the guideline: \u2022 Biological hazards during cooking. \u2022 Regulatory requirements associated with the safe production of cooked ready-toeat (RTE) products. \u2022 Options establishments can use to achieve lethality of *Salmonella* and other pathogens. \u2022 Processes that do not have validated research available (referred to as \u201cscientific gaps\u201d) and options establishments can use until research is available. Information included in the body of the guideline is intended as scientific support that can be used alone by establishments to meet Element 1 of validation (9 CFR 417.4(a)(1)) and to support decisions in the hazard analysis (9 CFR 417.5(a)(1)). The following topics are included in attachments to the guideline: \u2022 Resources for alternative support and \u2022 Recommendations for evaluating cooking deviations. Information provided in the attachments is not sufficient to use as sole support and additional documentation is needed. For example, Attachment A1. Customized Processes and Alternative Lethality Support (page 55), contains descriptions or brief summaries of available scientific articles. However, the summaries are not

considered adequate support on their own because they do not contain the details of each study. For this reason, establishments must have the full copy of the article on-file as scientific support for their HACCP System. The summaries are provided to help establishments identify journal articles related to their process. Each establishment needs to determine if the operating parameters of a particular study match the establishment's process. Establishments are not limited to using the scientific articles listed and summarized as support. In addition, Attachment A2. Cooking Deviations (page 66), contains recommendations for evaluating product safety in the event of a deviation but this information is not considered adequate support on its own because establishments should perform predictive microbial modeling and may conduct sampling and testing in order to support product disposition. Other information included in attachments is intended to be supplementary.", "9 Questions Regarding Topics in this Guideline If after reading this guideline you still have questions, FSIS recommends searching the publicly posted Knowledge Articles (\u201cPublic Q&As\u201d) in the askFSIS database. If after searching the database, you still have questions, refer them to the Office of Policy and Program Development through askFSIS and select HACCP Deviation & HACCP Validation as the Inquiry Type or by telephone at 1-800-233-3935. Documenting these questions helps FSIS improve and refine present and future versions of the guideline and associated issuances.", "10 FSIS Cooking Guideline for Meat and Poultry Products (Revised Appendix A) Background What is Lethality? Lethality treatments are processes used by establishments to eliminate Salmonella and other pathogens in RTE products. Lethality treatments achieve a specific reduction in the number of Salmonella and other pathogens in the product (i.e., an \u201cX-Log<sub>10</sub> colony forming units per gram1 (CFU/g)\u201d reduction). The combination of one or more lethality treatments must be sufficient to eliminate or adequately reduce Salmonella and other pathogens to undetectable levels and prevent the production of toxins or toxic metabolites in the RTE product (e.g., from *Staphylococcus aureus*). Establishments may use a variety of different lethality processes, such as: \u2022 Cooking the product (covered in this guideline). \u2022 Fermentation. \u2022 Drying. \u2022 Salt-curing. \u2022 Other processes that make the product safe for consumption. Products and Processes Covered by this Guideline This guideline addresses lethality of pathogens (e.g., Salmonella) in meat and poultry products<sup>2</sup> by heat treatment (cooking) including for products that are cooked to lethality but classified under a not-ready-to-eat HACCP plan. NOTE: FSIS has provided additional information about the safe production of meat and poultry jerky products in 1 In the rest of this document, Log<sub>10</sub> colony forming units per gram (Log<sub>10</sub> CFU/g) will be annotated simply as \u201cLog.\u201d All notations of \u201cLog\u201d should be read as in the unit Log<sub>10</sub> CFU/g unless other information is provided. 2 Throughout this document references to \u201cmeat and poultry products\u201d may be considered inclusive of meat by-products, meat food products, and poultry food products as defined in 9 CFR 301.2 and 9 CFR 381.1, unless otherwise stated (e.g., Products and Processes Not Covered by This Guidance). KEY DEFINITIONS A ready-to-eat (RTE) product is defined as a meat or poultry product that is in a form that is edible by the end consumer without additional preparation to achieve food safety and that may receive additional preparation for palatability, aesthetic, or culinary purposes (9 CFR 430.1). Lethality is the process (or combination of processes) that ensure a specific, reduction in the number of Salmonella and other pathogens in the product (i.e., an \u201cx-Log\u201d reduction). Lethality processes eliminate or adequately reduce Salmonella and other

pathogens and prevent the formation of their toxins or toxic metabolites, facilitating the production of a safe RTE food product.", "11 the FSIS Compliance Guideline for Meat and Poultry Jerky Produced by Small and Very Small Establishments. The information for jerky production remains in a separate guideline because of the complexities of the process, including drying procedures, and to help address questions from small and very small processing establishments. Products and Processes Not Covered by this Guideline The recommendations in this guideline do not apply to the following specific products: Fish of the Order Siluriformes (e.g., catfish) FSIS cooking guidance was not validated for fish of the order Siluriformes. Therefore, this guidance should not be used for fish. Fish establishments may use the cooking guidance in Table A-3 of The Food and Drug Administration\u2019s (FDA\u2019s) Fish and Fishery Products Hazards and Control Guidance as support for the cooking step of fish products. The time-temperature recommendations are designed to achieve a 6-Log reduction in Listeria monocytogenes (Lm). Pork Rind Pellets Establishments may cook pork skins in pork fat or oil for several hours rendering the fat and reducing the skin into pellets. This intermediate product is then further processed by frying to produce a finished product such as pork rinds, cracklins (cracklings), or chicharrones. FSIS cooking guidance does not apply to the cooking or rendering of pork skins into a pellet. Establishments may use the cooking requirements in 9 CFR 94.8(b)(4) as support for cooking pork skins into a pellet. Although these are Animal Plant and Health Inspection Service (APHIS) requirements for imported pork skins from countries where foot-and-mouth disease, African swine fever, classical swine fever, or swine vesicular disease exist, these cooking requirements ensure at least a 6.5-Log reduction of Salmonella (Juneja, et al., 2001a; Murphy et al., 2003; Murphy et al., 2004). NOTE: FSIS cooking guidance may be used for cooking of pork skins for products other than pork rind pellets (e.g., for use in pickled products) and for frying of pork rind pellets into popped pork skins. Guidance for monitoring the cooking critical limit for these products can be found in the Key Question on page 21. Rendered Lard and Tallow FSIS cooking guidance does not apply to the rendering of animal fats, such as lard and tallow, which, due to the high fat content, generally need to reach higher temperatures and longer dwell times to achieve the same reductions in Salmonella (RamirezHernandez et al., 2018). However, based on the D values (time at a constant temperature necessary to destroy 90% or 1-Log of the target organism) reported by Ramirez-Hernandez et al. (2018), the cooking requirements for rendering in 9 CFR 315.1(a) are adequate to ensure an animal fat rendering process achieves at least 6.5- 3 \u201cdwell time\u201d refers to the time a product is held at a specific temperature. Other commonly used terms such as \u201chold time\u201d or \u201crest time\u201d may be considered synonymous for the purpose of this guideline.", "12 Log reductions of Salmonella. Therefore establishments may use 9 CFR 315.1 as support for a lard or rendering process, provided the critical operational parameters (\u2265 170\u00b0F for \u2265 30 minutes) are met throughout the product. Dried Products Processed Under Dry Conditions FSIS cooking guidance does not support lethality for a process that relies on drying alone (e.g., biltong), nor does this guidance support a process where the drying step comes before a cooking step that does not apply humidity or does not apply humidity during cooking at sufficient levels to rehydrate the product surface (e.g., biltong or country-cured ham that is cooked in an unsealed oven after drying). This guidance also does not support lethality for a dried product cooked under moist conditions several times after drying (e.g., country-cured ham that is cooked in a sealed oven several times after the hams

have been salt-cured and dried). Such dried products are typically considered intermediate moisture foods (i.e., those foods that do not require refrigeration to control pathogens). The water activity range of foods considered intermediate moisture varies in the literature. For example, FDA classifies intermediate moisture foods as those with a water activity between 0.60 and 0.85 (FDA, 2018). However, some meat and poultry products may have a water activity > 0.85 and still be considered intermediate moisture because of other factors such as pH and salt concentration (Leistner, 1987). For example, country-cured ham has an average water activity of 0.88 but is considered shelf-stable due to the combination of water activity, high salt, and nitrite (Mikel and Newman, 2003; Reynolds et al., 2001). Establishments that apply these types of processes must identify other support for their HACCP System (9 CFR 417.5(a)(1) and 9 CFR 417.4(a)(1)). NOTE: This guidance includes critical operating parameters for cooking products which are dried, then cooked under moist conditions. Scientific Gaps Identified by FSIS describes critical operating parameters (page 47) and Attachment A6. Cooking Country-Cured Hams includes additional tips, specific to country-cured hams (page 90).

**Partially Heat-Treated NRTE Products** This guideline does not cover partially heat-treated products that are not ready-to-eat (NRTE) and did not reach a validated lethality time-temperature combination (for example: partially heat-treated bacon and hams). These products are addressed in the FSIS Stabilization Guideline for Meat and Poultry Products because cumulative growth of Clostridium perfringens and Clostridium botulinum are hazards of concern over the course of partial cooking and cooling processes.

**KEY DEFINITIONS** Stabilization is the process of preventing or limiting the growth of spore-forming bacteria capable of producing toxins either in the product or in the human intestine after consumption. Stabilization processes may include cooling, hotholding, or meeting and maintaining a certain pH or water activity level and other processes, such as drying and fermentation/ acidification that render the product shelf-stable or safe at room temperatures."

"<sup>13</sup> NOTE: As noted under the Products and Processes Covered by this Guideline, this guideline may be used for products that are cooked to lethality but classified under a Not RTE (NRTE) HACCP plan. For such products, please refer to the product reclassification guidance in the Listeria Guideline, Attachment 1.2 on pages 22-23 and Appendix 1.2 on pages 28-29 for guidance related to labeling, HACCP categorization, and intended use.

**RTE Multi-hurdle Products** This guidance does not address the safe production of products that rely on multiple hurdles to achieve lethality and shelf-stability (e.g., fermented and dried sausage). However, some regulatory information associated with such products is included in General Considerations for Designing HACCP Systems to Achieve Lethality by Cooking, page 18.

NOTE: Stabilization requirements and recommendations for cooling meat and poultry products after heat treatment are described in the FSIS Stabilization Guideline for Meat and Poultry Products.

**Biological Hazards of Concern During Cooking** The following section is designed to complement FSIS' Meat and Poultry Hazards and Control Guide and to further assist establishments in conducting a hazard analysis for cooked meat and poultry products as required by 9 CFR 417.2(a)(1) and for supporting decisions in their hazard analysis as required by 9 CFR 417.5(a)(1). The following hazard is present in raw products whose outgrowth during the heating come-up time should be controlled:

\u2022 *Staphylococcus aureus* (*S. aureus*)

The following are hazards present in raw products that the lethality treatment should be designed to destroy:

\u2022 *Salmonella*

\u2022 Shiga toxin-producing *Escherichia coli* (STEC) (in beef)

\u2022 *Campylobacter* (in poultry)

\u2022 *Lm*

\u2022 *Trichinae spiralis* and *Toxoplasma gondii*

(in pork, especially feral or nonconfinement raised swine) NOTE: Although all of these hazards are a concern, *Salmonella* is considered an indicator of lethality because the thermal destruction of *Salmonella* in cooked products would indicate the destruction of most other pathogens (64 FR 732). More details about *S. aureus* and *Salmonella* (an indicator of lethality) can be found on the following page.","14 *S. aureus* *S. aureus* is a bacterial pathogen that causes nausea, vomiting, and abdominal cramping with or without diarrhea. The Centers for Disease Control and Prevention (CDC) estimates over 240,000 illnesses annually in the U.S. are attributed to *S. aureus* (Scallan et al., 2011). *S. aureus* causes illness when the bacteria grows to high levels in food and one or more heat-stable enterotoxins are produced (Kadariya et al., 2014). Various types of foods serve as the optimum vehicle for *S. aureus*. The pathogen has been identified in meat products, such as fermented salami and brine-injected hams. In the 1980s, *S. aureus* enterotoxin outbreaks were frequently attributed to hams. Continued outbreaks at hotels, restaurants and institutions as documented in the National Outbreak Reporting System (NORS)<sup>4</sup> highlight that *S. aureus* is still a concern in hams particularly when prepared in these settings. For example, between 2013 to 2018, at least six *S. aureus* enterotoxin outbreaks at hotels, restaurants and institutions were reported in NORS in which ham was the suspected food vehicle. *S. aureus* can contaminate raw meat and poultry from the animal hide, skin, or tissue during slaughter. After slaughter and cooking, RTE meat or poultry products can be contaminated with *S. aureus* from handling by individuals carrying the organism. This pathogen is the main food safety concern during long heating come-up-times (CUT) (that is the amount of time product temperature is between 50 to 130°F while heating). *S. aureus* can be present on the raw meat or poultry and grow to high enough levels to produce a toxin in the food. Growth occurs from 45 to 118°F, but effectively begins at 60°F, especially in raw meats where the growth of other bacteria is inhibited by nitrite or salt. The critical level for human illness is 5-Log or higher which allows enterotoxin production (Kadariya et al., 2014). The toxin is not destroyed by the critical operating parameters described in this cooking guideline. FSIS recommends limiting the growth of *S. aureus* during processing to 2-Log or less. Normal levels of *S. aureus* in raw meat are usually 2-Log (Doyle and Buchanan, 2013; IFT, 2003; Waldroup, 1996). Limiting growth to 2-Log or less allows for a margin of safety before *S. aureus* would produce toxins. Conditions that allow 3-Log growth are considered a public health concern because they would result in a total of 5-Log *S. aureus* in the product which is considered the minimum critical level for human illness (Kadariya et al., 2014). To limit *S. aureus* growth, some establishments formulate products with antimicrobials such as phosphate or lactate. But the most common practice is to limit the amount of time products spend in the temperature range where *S. aureus* grows the fastest (i.e., 50 to 130°F). This guideline identifies CUT as a critical operating parameter to ensure lethality by cooking when applying the time-temperature tables (see FSIS Critical Operating Parameters for Cooking on page 23). FSIS is aware that establishments preparing some products (e.g., ham or beef brisket) may not be able to follow FSIS's Come-Up-Time Option because of the thermodynamics of the heating process. Therefore, FSIS identified long CUT as a Scientific Gap since support does not exist for many common processes (page 48). This gap supports the use of any of FSIS's applicable time-temperature combinations (pages 35, 37, 38) and relative humidity, 4 <https://www.cdc.gov/nors/index.html>,""15 without considering CUT as a critical operating parameter until research can be complete. *Salmonella* *Salmonella* is a bacterial

pathogen that causes diarrhea and fever. Infection with Salmonella may result in arthritis (Ajene et al., 2013). The CDC reports that nontyphoidal Salmonella species (spp.) is one of the leading causes of foodborne illness, with an estimated 1 million cases of foodborne Salmonella infection annually in the U.S (Scallan et al., 2011). Salmonella spp. infections are the second leading cause of foodborne illness in the United States. Meat and poultry outbreaks are frequently associated with Salmonella spp. Salmonella occurs naturally in raw animal products; however, Salmonella should not be found in RTE meat and poultry products because these products have undergone a lethality treatment. Also, RTE products are intended to be consumed without further preparation for safety (i.e., cooking), and if pathogens are present, their consumption may cause illness. FSIS considers all RTE meat and poultry products that are contaminated with Salmonella, as well as Listeria monocytogenes and STEC, to be adulterated under the Federal Meat Inspection Act and Poultry Products Inspection Act (21 U.S.C. 601(m)(1) and 453(g)(1)). Any detectable Salmonella or other pathogens of concern adulterates RTE products (64 FR 732). Salmonella as an Indicator of Lethality Meat and poultry products may be contaminated with Salmonella during the slaughter and dressing process and by crosscontamination in the processing environment when insanitary conditions are present. For cooked products, FSIS recommends that establishments use Salmonella as an indicator of lethality because the thermal destruction of Salmonella in cooked products would indicate the destruction of most other pathogens (64 FR 732). If the establishment's scientific support demonstrates that the lethality treatment achieves sufficient reduction in Salmonella, it does not need to provide additional support that adequate reduction of other pathogens such as STEC, Campylobacter, Lm, Trichinae spiralis or Toxoplasma gondii is achieved. As stated in the FSIS Compliance Guideline HACCP Systems Validation, establishments should not use pathogens other than Salmonella as indicators of lethality for cooked products unless the alternate pathogen displays similar or higher resistance to the lethality processes. NOTE: While Salmonella is considered an indicator of lethality for validation purposes, in the event of a deviation where the establishment missed its time-temperature parameters or applied insufficient relative humidity, FSIS recommends testing for other pathogens of concern (e.g., E. coli O157:H7 and Lm) because the absence of Salmonella does not KEY DEFINITIONS Critical operating parameters are those parameters of an intervention that must be met for the intervention to operate effectively and as intended. Such parameters include but are not limited to time, temperature, water activity, concentration, relative humidity, and type of equipment (to the extent that the use of different equipment would result in an inability to achieve the critical parameters of the study).", "16 assure the absence of other pathogens since the establishment was unable to follow the critical operational parameters in its scientific support. In addition, depending on the type of deviation, other pathogens may also be of concern (e.g., C. perfringens and C. botulinum). For more information see Attachment A2. Cooking Deviations, page 66. How to Control Salmonella Establishments must ensure the target Log reduction of Salmonella and other vegetative pathogens is achieved throughout the product. To ensure vegetative pathogens, including Salmonella, are killed on the interior of the product, the endpoint time-temperature combination the product achieves is a critical operating parameter. Most often, the target temperatures used during cooking reported in scientific support documents and this guideline are the internal temperatures that the product should reach. FSIS has found that some establishments use the recommendations established

for internal product temperature to set critical limits for the oven temperature. However, setting the oven temperature to the temperature identified in the FSIS time-temperature tables is not appropriate because doing so does not ensure that the product will reach the same target internal temperature. In addition to the product temperature, the amount of time the product is held at this temperature (also known as the dwell time) is also critical to ensuring that adequate lethality is achieved. If the product is held at the target temperature for less time than specified in the time-temperature tables in this guideline, then adequate lethality may not be achieved. To ensure a process achieves the target Log reductions of Salmonella on the surface of the product, moisture during cooking is a critical factor. Moisture (e.g., relative humidity) around a product during cooking promotes lethality on the product surface in two ways: \u2022 Moist cooking reduces surface evaporation from the product during heating (evaporative cooling). Producing products under conditions of high moisture early in the cooking process reduces evaporative cooling allowing product surfaces to reach higher temperatures resulting in a greater reduction in microorganisms; and \u2022 Moist cooking keeps the product surface (and any pathogens) wet which prevents product drying. Product drying reduces the water activity and concentrates solutes (e.g., sugar and salt). Research has demonstrated that bacteria can become more heat tolerant as their moisture levels decrease, and increased concentrations of solutes, especially salt, increase the heat resistance of bacteria (Buege et al., (2006), Boles et al., (2004), and Sindelar et al., (2016)). Therefore, drying of the product surface before pathogens are destroyed will increase pathogen heat resistance and allow the pathogens to survive the heating process. By incorporating moisture (e.g., relative humidity) to minimize evaporation and the loss of surface moisture from the product, the D values (time at a constant temperature necessary to destroy 90% or 1-Log of the target organism) that are the basis for the "17 time-temperature combinations, will remain valid (Goepfert, 1970; Goodfellow and Brown, 1978). If evaporation, drying, or an increase in solute concentration is likely to occur, the times and temperatures in scientific studies and supporting documentation are not likely to be sufficient to provide the required lethality. How does Moisture Ensure Bacteria on the Surface are Killed During Cooking? During cooking, achieving a high oven temperature and internal product temperature alone are not enough to ensure the final product is free of harmful bacteria. Establishments need to make sure that cooking is done in a moist environment to ensure lethality. When relative humidity is low, oven air is dry, and a process called evaporative cooling increases, which is something we do not want. Evaporative cooling is the same thing that allows humans to keep cool by sweating. When you get too hot, you produce sweat, and when that sweat evaporates, it cools you down. Evaporation equals cooling. Just like on a person's skin, evaporative cooling cools down the surface of meat and poultry during cooking. Although the oven is hot, because the surface of the product is cooling down, that moisture evaporation can actually prevent the surface of the product from becoming hot enough to kill off harmful bacteria. We can reduce evaporative cooling by keeping the humidity in the oven high. That way the moisture in the product does not evaporate as quickly, keeping the meat's surface moist and hot and resulting in an adequate bacterial kill. Why does this work? Imagine that you are in New Mexico or Nevada where it is really hot, but dry. If you're outside, you're more likely to sweat and that sweat will cool you down, so you don't feel as hot. Now imagine you're in Florida where it is not only really hot, but also humid. If you're outside where it is humid,

your skin\u2019s surface will stay sweaty and hot, your sweat will not evaporate, and you will not cool down. Since the air is already saturated, or full of moisture (humid), there is less evaporation from your body and, therefore, less cooling. The way humidity keeps you hot in Florida is the same way moisture keeps meat and poultry products hot, too. When you get too hot\u2026 \u2026you produce sweat. When that sweat evaporates\u2026 \u2026it cools you down. Evaporation = Cooling VS. Desert Dry Heat = Cooling Down Tropical More Humidity = Less Cooling", "18 General Considerations for Designing HACCP Systems to Achieve Lethality by Cooking Addressing Lethality in the HACCP System FSIS has established performance standards in the regulations for specific ready-to-eat (RTE) products. The performance standards for specific products set required levels of Salmonella lethality during cooking as follows: \u2022 Cooked poultry products must be processed to achieve at least a 7-Log reduction of Salmonella or an alternative lethality per 381.150(a)(1). \u2022 Roast, cooked, and corned beef must be processed to achieve at least a 6.5-Log reduction of Salmonella or an alternative lethality (e.g., at least a 5-Log reduction) per 9 CFR 318.17. \u2022 Cooked uncured meat patties must be processed to meet or exceed the time-temperature combinations listed in 9 CFR 318.23, which will achieve a 5-Log reduction of Salmonella (and other pathogens including STEC). For products that are not subject to a performance standard, FSIS recommends the following pathogen Log reductions (i.e., targets) be achieved in order to support decisions in the hazard analysis (9 CFR 417.5(a)(1)): \u2022 For cooked meat products, FSIS recommends that establishments achieve a target 6.5-Log or 5-Log reduction of Salmonella in their process. To use a target 5-Log reduction, establishments should provide additional support for the safety of their process (see Supporting an Alternative Lethality Target (e.g., 5-Log) page 57). \u2022 For shelf-stable meat products, FSIS recommends that establishments achieve a target 5-Log reduction of Salmonella (see How is Alternative 5-Log Lethality Related to Risk of Foodborne Illness? page 57). KEY DEFINITIONS Performance standards described in this guideline are quantifiable pathogen reduction levels or growth limit requirements set by FSIS for lethality and stabilization of certain meat and poultry products. A Log reduction is a 90% reduction of a pathogen. For example, a 2-log reduction is a 99% reduction of a pathogen and a 3-log reduction is a 99.9% reduction of a pathogen in a product. Targets are quantifiable pathogen reduction levels or growth limits set by the establishment to produce safe products in the absence of regulatory performance standards. An alternative lethality is a treatment that achieves a different (often lower) Log reduction than what is prescribed in the regulations for certain products, but still achieves an equivalent probability that no viable Salmonella cells remain in the finished product, nor other pathogens and their toxins or toxic metabolites. An alternative lethality prevents adulteration and must be demonstrated to be achieved throughout the product (9 CFR 318.17(a)(1)).", "19 An establishment should identify the performance standard or specific Log reduction target its process is designed to achieve in its HACCP plan or supporting documentation. If it does not, and FSIS cannot determine the pathogen reduction level the process achieves, FSIS may determine the establishment lacks support for its decisions related to Salmonella control (9 CFR 417.5(a)(1)). In addition, according to 9 CFR 417.2(c)(3), establishments must design their critical limits for Critical Control Points (CCPs) to meet all applicable performance standards and targets. NOTE: If an establishment uses the time-temperature tables provided in this guideline or cooks beef patties according to 9 CFR 318.23, it does not need to indicate the specific Log reduction that its process achieves. It would be sufficient for the establishment to indicate that

it uses time-temperature combinations from one of these documents as these regulations were designed to achieve a 5-log reduction in Salmonella and other pathogens including STEC. Establishments are also required to validate that their HACCP system works as intended to address these hazards (9 CFR 417.4(a)). For more information on validation see the HACCP Systems Validation Guideline. Key Question Question: When a RTE meat food product is a mixture of meat and poultry such that the product has a meat legend, and the establishment is following this cooking guideline, does the RTE meat food product need to comply with the regulatory requirement found in 9 CFR 381.150(a)(1)? Question: If a RTE meat food product has any amount of poultry in it, does it automatically have to meet the poultry Log reduction in the FSIS Time-Temperature Tables? Answer: Yes to both questions. RTE meat or poultry food products consisting of any combination of meat and poultry must meet the poultry lethality performance standard in 9 CFR 381.150(a)(1). Under the published final rule \"Performance Standards for the Production of Certain Meat and Poultry Products,\" cooked product with any amount of poultry needs to meet the lethality requirements for the production of fully cooked poultry products (9 CFR 381.150(a)(1)) which stipulate a 7-Log Salmonella reduction or an alternative lethality that achieves an equivalent probability that no viable Salmonella organisms remain in the finished product. This provision is based on the FSIS national microbiological \"baseline\" survey of raw whole and ground meat and poultry products, which found higher levels of Salmonella in poultry than in meat (USDA 1994, 1996a-f). Consequently, FSIS established a higher lethality performance standard for RTE poultry products than for meat (based on highest \"worst case\" levels).\" 20 Alternative Lethality An alternative lethality is a treatment that achieves a different (often lower) Log reduction than what is prescribed in the regulations but still achieves an equivalent probability that no viable Salmonella cells remain in the finished product, as well as ensures the reduction of other pathogens and their toxins or toxic metabolites (e.g., from *S. aureus*) necessary to prevent adulteration. Establishments may use alternative lethality treatments to meet the performance standards (9 CFR 318.17(a)(1) and 9 CFR 381.150(a)(1)). When using an alternative lethality treatment (e.g., at least a 5-Log reduction of Salmonella), the establishment must validate its HACCP system to ensure that no viable Salmonella organisms (that is no organisms capable of causing human illness) remain in the finished product. Risk assessments have demonstrated that achieving a 5-Log reduction of Salmonella (instead of a 6.5-Log reduction) in cooked meat and poultry products that are not shelf stable is less protective of public health (Refer to text box: How is Alternative 5-Log Lethality Related to Risk of Foodborne Illness? page 57). Therefore, to use these lower targets, the establishment must provide additional support for its process as described in Attachment A1. Customized Processes and Alternative Lethality Support: Supporting an Alternative Lethality Target (e.g., 5-Log) on page 55. In contrast, risk assessments have shown that for shelf-stable meat and poultry products, a 5-Log reduction of Salmonella (instead of a 6.5-Log or 7Log reduction) is sufficient. Therefore, no additional support is needed to use a 5-Log reduction process in these shelf-stable products (9 CFR 417.5(a)(1) and 9 CFR 417.4(a)(1)). Monitoring, Calibration, and Recordkeeping The establishment\u2019s cooking procedures should be designed to ensure all products in a batch or lot achieve lethality, and the monitoring procedures should be designed to detect a deviation when it occurs. To achieve these goals, establishments should carefully consider the selection of the critical limit, as well as the design of their monitoring procedures. Lessons learned from several recalls attributed, in part, to

insufficient monitoring procedures are shared on page 22. Selection of the critical limit Establishments producing cooked meat and poultry products should have sufficient monitoring equipment, including recording devices, to assure that the time, temperature, and relative humidity operating parameters of their processes are being met. With any monitoring equipment, the establishment should take the normal variation of the monitoring equipment into account when designing the critical limits. For example, if a minimum internal temperature of 165°F is necessary to destroy pathogens in a product and the thermometer has an accuracy of ±1°F (plus or minus one degree), then the critical limit should be set no lower than 166°F. The written reasoning and equipment specification materials should be kept as part of the establishment's supporting documentation for its HACCP plan and the selection of its critical limit (9 CFR 417.5(a)(2)). All supporting documents and data from the recording devices must be made available to FSIS employees upon request (9 CFR 417.5).<sup>21</sup> Selection of the monitoring procedures Establishments are required to maintain documents supporting the selection of monitoring procedures and associated monitoring frequencies (9 CFR 417.5(a)(2)). It is important that establishments take into account variation within the cooking process when developing monitoring procedures to ensure the procedures they develop can identify any deviations. In addition, to accurately measure the internal temperature of the meat or poultry product, an establishment should understand the factors that can affect this temperature. These factors include cold spots in the oven, as well as variations in oven temperature during different seasons. Establishments should be aware that updated smokehouses that contain alternating or rotating dampers that result in varying breakpoints throughout the oven do reduce the temperature difference throughout the oven, but they do not eliminate it. Although monitoring the internal product temperature is strongly encouraged, an establishment can use the oven or smokehouse temperature in place of the product temperature, provided that the establishment has a consistent product and process and has sufficient data on file correlating the oven temperature selected with the internal product temperature in the scientific support. A disadvantage with monitoring oven temperature alone is that it may make supporting product disposition after a cooking deviation more difficult. In many cases, FSIS recommends using predictive microbial modeling programs to evaluate potential hazards (see Attachment A2. Cooking Deviations on page 66). Microbial modeling programs use product temperature to predict pathogen growth and potential Log outgrowth or reductions achieved. Without product temperature records, the establishment would need other support (e.g., product testing) to determine product disposition.

Key Question: How does an establishment develop a monitoring procedure for measuring endpoint temperature in meat or poultry products that are fried crispy such that a probe cannot be inserted into the product to measure internal temperature (e.g., popped pork skins, and bacon slices, pieces, or bits) because the product is too thin or hard or because the thin product cools as soon as the product exits the cooking medium? Answer: Depending on the product type, there are different recommendations. For example, for a product such as bacon slices, it may be possible to cut a slice twice as thick as normal so that the probe can be inserted. If this thicker piece reaches the lethality temperature, the thinner pieces should as well. This procedure is also recommended for jerky. It is not recommended to fold a piece of product over the thermometer, as this has been found to result in inaccurate temperatures (Buege et al., 2006). For small products, such as bacon pieces or bits, it may be possible to pile

the pieces or bits around the thermometer for measurement. If none of these procedures can be used, establishments may use other quantifiable measures such as a color scale value that is correlated to crispiness or the number of pieces that pass as \"fried until crispy in all parts\" based on a visual assessment as the critical limit for lethality for these products due to the physical challenges in monitoring the internal temperature, and the lack of outbreaks associated with them." "22 Lessons Learned from Undercooked Product Recalls In 2016 and 2017, there were five recalls associated with under-cooked RTE poultry products (RC-106-2016, RC-110-2016, RC-115-2016, RC-017-2017, and RC-0372017). For each of these recalls, FSIS determined that even though the establishments had documentation showing the critical limit (either 160\u00b0F or 165\u00b0F) was met, there were still pieces that may have entered commerce undercooked, indicating a loss of process control and insufficient monitoring procedures to identify a process deviation. Investigations revealed a variety of concerns related to monitoring procedures, including taking temperatures from products not in the coldest spot, taking multiple product temperatures, and averaging the results of multiple temperature measurements as opposed to recording the lowest temperature. Investigations also revealed a variety of contributing factors for inadequate cooking including: \u2022 Raw product was partially frozen. \u2022 Belt speed was increased. \u2022 Shorter dwell time and lower oven temperature than normal were used. \u2022 Product was stacked during sous vide cooking, preventing full immersion of the bags into the liquid cooking medium. \u2022 Higher than normal product load overwhelmed the oven. Each of these practices may have led to uneven or inadequate cooking. These findings also highlight the importance of maintaining process control of critical operating factors, such as oven temperature, product load, and belt-speed that affect the final product temperature, dwell time, and relative humidity. The establishment is required to validate that the entire HACCP system is operating as intended and to verify that it is producing a safe and wholesome product on an ongoing basis. Complete failure to document critical limit monitoring has also contributed to the recall of cooked poultry products in the past due to a processing defect (RC-009-2017). Such a failure highlights the importance of accurate records documenting the implementation of the critical operating parameters to support the production of safe products. Corrective Actions under HACCP Cooking Deviations Cooking deviations occur when an establishment fails to meet its cooking CCP critical limit or cooking humidity option. Common causes for cooking deviations include product overlap, power failures, or breakdown of cooking equipment. The HACCP regulations require establishments to take corrective actions in response to these deviations, regardless of whether the cooking process is addressed through a CCP or prerequisite program. Corrective actions include ensuring no product that is injurious to health or otherwise adulterated because of the deviation enters commerce and supporting product disposition decisions (9 CFR 417.3(a) and (b))." "23 When cooking is addressed through a CCP, establishments are required to determine the cause of all cooking deviations, no matter how small (9 CFR 417.3(a)(1)), and ensure measures are established to prevent recurrence (9 CFR 417.3(a)(3)). Continual or repetitive process deviations from the critical limit demonstrate that the establishment is unable to control its process. When cooking is addressed through a prerequisite program, establishments are required to reassess their HACCP system to determine whether the newly identified deviation or unforeseen hazard should be addressed and incorporated into the HACCP plan (9 CFR 417.3(b)(4)). Also, an establishment may not be able to continue to support the decision in

its hazard analysis that pathogens are not reasonably likely to occur, if it has continual or repetitive deviations from its cooking prerequisite program (9 CFR 417.5(a)(1)). For more information on evaluating product disposition after a cooking deviation see Corrective Actions to Perform When a Cooking Deviation Occurs (page 66). FSIS Critical Operating Parameters for Cooking (Time-Temperature Tables) Establishments that cook products to achieve lethality by applying the time-temperature combinations from this guideline need to consider the critical operating parameters that may affect pathogen Log reductions, specifically: \u2022 Come-up-time (CUT), \u2022 Relative Humidity, and \u2022 Endpoint Time-Temperature. Additionally, establishments cooking poultry products need to consider product species composition and fat content if applying FSIS cooking lethality guidance in the tables on pages 37 and 38. The FSIS Cooked Poultry Rolls Options (page 39) apply to all poultry products regardless of poultry species or fat content. For information about why product species should be considered when applying cooking lethality guidance on pages 37 and 38 and not when applying the FSIS Cooked Poultry Rolls Options see page 36. Come-Up-Time (CUT) When applying one of the time-temperature tables from this guideline, an establishment must also consider the heating CUT to be a critical operating parameter unless the establishment can provide a science-based rationale why heating CUT does not need to be addressed. For example, products that are fermented and then cooked to lethality may control *S. aureus* outgrowth by lowering the pH following the degree-hour concept as recommended in the American Meat Institute\u2019s Good Manufacturing Practices for Fermented Dry & Semi-Dry Fermented Sausage Products and therefore would not address CUT." "24 FSIS has developed a CUT Option that establishments may use to support its process control of *S. aureus* growth, specifically \u2264 2-Log that also prevents enterotoxin formation: Come-Up-Time Option: Total time product temperature is between 50 and 130\u00b0F is 6 hours or less. NOTE: This CUT Option is only for products that were cooked to lethality (including those cooked to lethality but classified as NRTE under a heat treated, not fully cooked, not shelf-stable HACCP plan). Please refer to the FSIS Stabilization Guideline for Meat and Poultry Products for the Agency\u2019s recommendations regarding CUT in partially cooked products that do not receive a full lethality. Please also refer to the product reclassification guidance in the Listeria Guideline, Attachment 1.2 on pages 2223 and Appendix 1.2 on pages 28-29. FSIS is aware that establishments preparing some products (e.g., ham or beef brisket) may not be able to follow FSIS\u2019s Come-UpTime Option above because of the thermodynamics of the heating process. Therefore, FSIS identified long CUT as a Scientific Gap since support does not exist for many common processes (page 48). Additionally, alternative support for certain long CUT processes have been included in Attachment A1. Customized Processes and Alternative Lethality Support (page 55). Temperatures referred to in FSIS\u2019s Come-Up-Time Option above, are internal temperatures. However, establishments may monitor surface temperatures during CUT, if the establishment provides support the product is intact and processed so pathogens have not been introduced below the product surface. Non-intact product temperatures should be taken internally at the center of the product (see Key Definitions panel to the right for an explanation of intact and nonintact products). Establishments should also take temperatures at the center of the product for products such as deboned and rolled hams where a portion of the product is rolled or folded over and pathogens may be internalized. NOTE: FSIS time-temp tables list internal endpoint temperatures during cooking. It is not supportable to use surface temperature to address

endpoint temperature. FSIS is only making this recommendation for its CUT option. KEY DEFINITIONS Come-up-time refers to the amount of time product temperature is between 50130\u00b0F while heating. Intact refers to products where the interior remains protected from pathogens migrating below the exterior\outside (such as beef brisket or a picnic shoulder that is not injected or vacuum tumbled). Non-Intact refers to products where pathogens may have been introduced below the surface. Examples include products that have been mechanically tenderized (including those that have been injected with marinade or solution) or vacuum tumbled.","25 Relative Humidity FSIS time-temperature tables use relative humidity as a critical operating parameter to ensure moist cooking and adequate surface lethality. An establishment that uses the FSIS time-temperature tables to support its cooking process must address humidity, unless it meets one of the criteria listed in Situations when Humidity is Not Needed (page 31) or provides additional support for why humidity would not be needed in its process to ensure lethality on the product surface. FSIS has included specific relative humidity options for use with the timetemperature tables (page 26). Additional resources for determining which relative humidity option to adopt are included in Relative Humidity Resources (page 28). NOTE: FSIS is aware that some establishments may not be able to use FSIS\u2019s humidity options because of the nature of the cooking process. Examples include products cooked for short times at high temperatures (e.g., for meat balls or chicken tenders) or other processes that do not allow the use of humidity (e.g., barbecue products cooked under dry heat including those cooked in smokehouses or open pits). Please refer to Scientific Gaps Identified by FSIS (page 41). Selection of the proper relative humidity option depends on the endpoint time-temperature. Products cooked to endpoint time-temperatures of at least 145\u00b0F plus the dwell time, may apply any of the relative humidity options in Table 1.

**Critical Operating Parameters for FSIS Humidity Options.** Key Question Question: An establishment cooks a brisket to full lethality but realizes the smoke coloring is too light and wants to recook it to deepen the color. Can the establishment apply a new 6 hour CUT for the second cook? Answer: Yes. Once a product achieves a lethal time-temperature combination, the allowed CUT is reset for the next cook. If the establishment chooses to recook the product, it may apply a new 6 hour CUT limit (page 23). However, if the product did not achieve a lethal time-temperature combination during the first cooking process, the CUT does not start over. The establishment should support the total time product temperature is between 50 and 130\u00b0F is 6 hours or less. Please review Attachment A2. Cooking Deviations subsection Missed Time-Temperature Parameter (page 67) for additional information. KEY DEFINITIONS Maintaining humidity means keeping the humidity at the same level throughout the cooking process. If the humidity drops during the cooking process, the establishment will need to provide additional support for the safety of the product A sealed oven is generally defined as one in which the smokehouse doors and oven dampers are closed to prevent moisture loss. The cooking time includes the time the product is placed in the heated oven (including surface preparation and color setting) until the product reaches the desired lethality timetemperature combination (also referred to as the \u201clethality treatment\u201d).","26 However, products cooked to an endpoint less than 145\u00b0F, should select Option 3 or 4 in Table 1. Critical Operating Parameters for FSIS Humidity Options depending on total cooking time. NOTE: To be most effective, humidity needs to be applied during the lethality treatment, before drying. Using this guideline to support lethality processes in which the drying step comes before the

moist cooking step (e.g., country-cured ham) creates a vulnerability in the establishment's HACCP system. Establishments using this guideline for these processes should read Attachment A6. Cooking CountryCured Hams (page 90) for recommendations to reduce this vulnerability, such as measuring water activity after cooking to verify it increases and the product surface was rehydrated during cooking. To ensure that adequate humidity is attained, the establishment should monitor the humidity throughout the lethality treatment. The process should be monitored using wet and dry bulb thermometers (used to determine relative humidity) or a humidity sensor. FSIS recommends that establishments monitor relative humidity for every lot or batch of product produced. Table 1. Critical Operating Parameters for FSIS Humidity Options CRITICAL OPERATING PARAMETERS Relative Humidity Endpoint

Temperature Cooking Time OPTION 1: The relative humidity of the oven is maintained by continuously introducing steam for 50 percent of the cooking time, or 1 hour, whichever is longer. \u2265145\u00b0F + dwell time \u22651 hour OPTION 2: The relative humidity of the oven is maintained by a sealed oven for at least 50 percent of the total cooking time, or 1 hour, whichever is longer. \u2265145\u00b0F + dwell time \u22651 hour OPTION 3: The relative

humidity of the oven is maintained at 90 percent or above for at least 25 percent of the total cooking time, or 1 hour, whichever is longer. Any \u22651 hour OPTION 4: The relative humidity of the oven is maintained at 90 percent for the entire cooking time. Any Any",<sup>27</sup>

Current Support for FSIS Relative Humidity Options Although the research cited as the basis of FSIS guidance dates as far back as 1978, newer research by McMinn et al., (2018) supports that the time-temperature parameters in FSIS's cooking guidance achieves sufficient reductions of Salmonella. This research by McMinn et al. (2018) was conducted with product cooked in vacuum-sealed bags supporting the importance of cooking in a high moisture environment. While newer research has not been conducted to validate the sealed oven and steam injection relative humidity options, research does continue to support the importance of moisture during cooking. For example, Mann and Brashears (2007), support the need for at least 30% relative humidity during cooking of roast beef. Based on FSIS knowledge of establishments' processes through its verification activities, the Agency believes when the oven is sealed, or steam is introduced, at least 30% relative humidity is maintained, suggesting that these practical recommendations result in adequate relative humidity. The Agency is also not aware of any establishments that have had Salmonella positives or been associated with a salmonellosis outbreak when following FSIS temperature, time, and relative humidity guidance while using effective monitoring procedures.

Key Question Question: To follow the sealed oven or steam injection options, must establishments achieve a specific relative humidity? Answer: No. Establishments do not need to achieve a specific relative humidity level in the oven if they are following the steam injection or sealed oven options in this guideline as their scientific support. Based on expert opinion, the 2014 FSIS Jerky Guideline recommended that establishments producing jerky that monitor relative humidity try to achieve a wet bulb temperature of at least 125-130\u00b0F for 1 hour or more along with a corresponding dry bulb temperature needed to achieve at least 27-32% relative humidity or more. However, the Jerky Guideline also noted, achieving a wet bulb temperature of at least 125-130\u00b0F and at least 27-32% relative humidity for 1 hour or more is not adequate on its own to support that the process is being implemented consistently with FSIS Humidity Options. Rather, establishments should ensure that all critical operating parameters described in this

guidance are met. Relative Humidity Resources (page 28 contains specific guidance for how to implement Option 1 steam injection and Option 2 sealed oven in a validated HACCP system. In addition, establishments should not apply the wet-bulb and relative humidity recommendations in the Jerky Guideline to other products without additional support.)

Relative Humidity Resources The following flow chart contains specific guidance for how to choose a humidity option and the resources on the next two pages are designed to help establishments implement Option 1 steam injection and Option 2 sealed oven in a validated HACCP system.

Flow Chart to Choose a Humidity Option

- \*Relative humidity (RH) is 90% or higher for at least 25% of the total cooking time, or 1 hour, whichever is longest.
- \*\*RH is maintained for 50% of the cooking time, or 1 hour, whichever is longest

For more information, refer to FSIS Relative Humidity Options on page 25.

\u2014 wouldn\u2019t it be good to put the information together? Additionally, the following information in the FSIS Jerky Guideline can be useful when deciding which humidity option to adopt:

- \u2022 Instructions for making your own wet bulb (reprinted with permission from the University of Wisconsin, page 49); and
- \u2022 An example of a time-temperature recorder chart to support the option of continuously injecting steam (page 53).

\*Relative humidity (RH) is 90% or higher for at least 25% of the total cooking time, or 1 hour, whichever is longest.

\*\*RH is maintained for 50% of the cooking time, or 1 hour, whichever is longest

For more information, refer to FSIS Relative Humidity Options on page 26.

Additionally, the following information in the FSIS Jerky Guideline can be useful when deciding which humidity option to adopt:

- \u2022 Instructions for making your own wet bulb (reprinted with permission from the University of Wisconsin, page 49); and
- \u2022 An example of a time-temperature recorder chart to support the option of continuously injecting steam (page 53).

Specific Guidance for Using the Sealed Oven Option To support the use of the sealed oven option for addressing relative humidity, FSIS recommends establishments follow all 4 steps below:

- 1) Maintain documentation that supports that the product achieves an internal product temperature equal to or greater than 145\u00b0F (plus the required dwell time) from the FSIS time-temperature tables. Such documentation could include:
  - a. Records of internal product temperature and time held at that temperature, (if applicable); or
  - b. Records of the oven or smokehouse temperature in place of internal product temperature provided that the establishment has a consistent product and process and has sufficient data correlating the oven temperature selected with the internal product temperature in the scientific support;
- 2) Maintain documentation that supports that the oven dampers are closed for at least one hour or 50% of the cooking time, whichever is longer. Such documentation could include:
  - a. Records from a computerized system that document the time at which the oven dampers were open and were closed; or
  - b. Records, made manually, of the times at which the oven dampers were open and closed;
  - c. Records demonstrating that the relative humidity level in the oven is maintained for at least one hour or 50% of the cooking time, whichever is longer (e.g., by use of dry and wet bulb thermometers to calculate the relative humidity or use of a humidity sensor that provides a direct measurement) with correlation data supporting a relationship between the relative humidity level in the oven and the time at which the oven dampers were open and closed;
- 3) Maintain documentation that supports that when the oven dampers are closed, humidity is maintained in the ovens. Such documentation could include:
  - a. Records demonstrating the relative humidity level in the ovens is maintained (e.g., by use of dry and wet bulb thermometers to calculate the relative humidity

or use of a humidity sensor that provides a direct measurement), or b. Data gathered during the initial validation period along with ongoing verification that demonstrate that the relative humidity in the oven is maintained while the dampers are closed; and 4) Perform routine checks to ensure the oven dampers are properly working along with a maintenance program that includes periodic monitoring to ensure oven seals are intact and functional, and that when the oven dampers are closed, a tight seal is obtained. A tight seal is one that prevents a significant loss of humidity. FSIS acknowledges that a small amount of smoke or vapors might be seen escaping the smokehouse even when a tight seal is obtained. FSIS also recommends establishments consider whether there are other openings, particularly in older smokehouses, such as drain valves or air intake valves that need to be closed to ensure that a seal is obtained. Finally, some older ovens may have a stack or other opening that cannot be closed. For those establishments with older ovens that cannot be completely closed, the sealed oven method should not be used. However, the establishment may choose to close the parts of the oven it can, then add moisture in the system either by continuously introducing steam, or by using another validated method." "30 Specific Guidance for Using the \u201cContinuously Introducing Steam\u201d Option To support the use of the continuously introducing steam option for addressing relative humidity, FSIS recommends establishments follow all 3 steps below: 1) Maintain documentation that supports that the product achieves an internal product temperature equal to or greater than 145\u00b0F (plus the required dwell time) from the FSIS time-temperature tables. Such documentation could include: a. Records of internal product temperature and time held at that temperature, (if applicable); or b. Records of the oven or smokehouse temperature in place of internal product temperature provided that the establishment has a consistent product and process and has sufficient data correlating the oven temperature selected with the internal product temperature in the scientific support; 2) Maintain documentation that supports that steam is continuously introduced for at least one hour or 50% of the cooking time, whichever is longer. Such documentation could include: a. Records from a computerized system that contains the time at which the steam is turned on and off; or b. Records, made manually, of the times at which the steam is turned on and off; or c. Records demonstrating the relative humidity level in the oven is maintained for at least one hour or 50% of the cooking time, whichever is longer (e.g., by use of dry and wet bulb thermometers to calculate the relative humidity or use of a humidity sensor that provides a direct measurement), along with correlation data supporting a relationship between the relative humidity level in the oven and the time steam is turned on or a letter from the manufacturer stating that when the relative humidity is rising, it is because of live steam injection; and 3) Maintain documentation that supports that when steam is injected, humidity is maintained in the ovens. Such documentation could include: a. Records demonstrating the relative humidity level in the ovens is maintained (e.g., by use of dry and wet bulb thermometers to calculate the relative humidity or use of a humidity sensor that provides a direct measurement), or b. Data gathered during the initial validation period along with ongoing verification which demonstrates that the relative humidity in the oven is maintained while steam is being injected. NOTE: The \u201ccontinuously introducing steam\u201d option refers to the use of live steam. This option may also apply to establishments that spray water onto hot heating elements, which creates steam that in turn produces humidity in the smokehouse. \u201cContinuous\u201d does not mean that the steam is injected for at least

one hour during one stage. Rather, steam could be injected during specific stages or time intervals during the lethality (cooking) treatment as long as the total amount of time the steam is introduced adds up to at least one hour or 50% of the cooking time, whichever is longer. Furthermore, the establishment may turn the steam on and off throughout the cooking time when the target humidity is reached.","31 Situations when Humidity is Not Needed FSIS recognizes two situations when humidity does not need to be addressed to ensure adequate lethality: 1. When moisture is inherently maintained; or 2. When product is cooked using direct heat. Relative humidity does not need to be addressed when moisture is inherently maintained around the product. Examples of these types of processes include, but are not limited to:

- \u2022 Completely immersing the meat or poultry product in a liquid cooking medium throughout the entire cooking process;
- o E.g., unbagged, in water
- \u2022 Cooking the product in a sealed, moisture impermeable bag (e.g., cook-in-bag meat or poultry);
- o Cook-in-bag products may be eligible to be labeled as \u201cpasteurized\u201d (see Attachment A3. When can Products be Labeled as Pasteurized? page 81).
- \u2022 Cooking product in a casing that holds moisture (e.g., natural casings, cellulose casings, collagen casings, fibrous casings and plastic casings (sometimes called \u201csynthetic\u201d casings)).
- o See the question box on page 33 for information on cooking using natural casings.
- \u2022 Heating meat or poultry products that weigh 10 pounds or more in an oven maintained at 250\u00b0F (121\u00b0C) or higher throughout a process achieving one of the timetemperature combinations in this guideline.

NOTE: Humidity is not needed for products that weigh 10 pounds or more in an oven maintained at 250\u00b0F (121\u00b0C) or higher because they have a low surface to mass ratio (Goodfellow and Brown, 1978). Therefore, the surface dries out slower than smaller products and *Salmonella* is less likely to become heat tolerant. Establishments that use processes that match one of these situations do not need to monitor relative humidity as a critical operating parameter in their cooking procedure.

**Key definitions**

**Convective heating**: Heat is transferred directly into the food product by physical contact with the heating medium (e.g. heating product on a skillet).

**Radiant heating**: Heat is transferred directly into the food product by radiant energy without the movement of air or physical contact between the source and the food. Two common examples: Radiant energy from the sun warms Earth across the vacuum of space, or a flame emits radiant energy to heat food product in certain rotisserie ovens. Various forms of radiant energy also include gamma rays, electron beams, x-rays, and microwaves.

**KEY DEFINITIONS**

During convective heating the food product is indirectly heated by the movement of hot air. This type of heating is typical for solid foods cooked in a smoke house oven.

**Conductive Heating**: Heat is transferred directly into the food product by physical contact with the heating medium (e.g., heating product in a skillet).

**Radiant Heating**: Heat is transferred directly into the food product by radiant energy without the movement of air or physical contact between the source and the food. Two common examples: are (1) broiling where food is exposed to direct, intense radiant heat or (2) certain types of rotisserie ovens where a flame emits radiant energy to heat food.

Forms of radiant energy also include gamma rays, electron beams, and x-rays.","32 Relative humidity also does not need to be addressed for processes that apply direct heat via conduction or radiant heating. Unlike convective heating, which uses moving hot air or steam to heat the product (e.g., smoke house ovens, spiral ovens, impingement ovens), direct heating (e.g., conductive heating, radiant heating) puts the product in direct contact with the heating

medium. Direct heat ensures the product surface quickly reaches lethality temperatures before bacteria can develop heat tolerance due to the product's surface quickly drying out. Examples of direct heat include: Grill. Broil (exposure to direct, intense radiant heat). Heating coil, Flame. Certain rotisserie ovens that cook the meat or poultry over the heat source resulting in a product with a grilled quality. NOTE: Direct heat cooking is rarely used in conjunction with rotisserie cooking. Indirect heat cooking is most often used because it allows the meat or poultry to cook slowly and evenly, which is the primary purpose for using a rotisserie for cooking. For indirect heat cooking, the rotisserie is positioned in front of or next to the heat source and it is the heated air that cooks the product (convection cooking). Cooking meat patties per 9 CFR 318.23 does not include humidity considerations because these products were assumed to be cooked with direct heat such as a grill, heating coil, or flame. Meat patties cooked per 9 CFR 318.23 do not need to address relative humidity. For the definition of a patty see 9 CFR 318.23. NOTE: Products cooked using microwave cooking methods that are not designed to control relative humidity is considered a Scientific Gap because these common cooking processes can't achieve the relative humidity options included in this guideline; however, there is a lack of research to support alternative parameters. For the critical operating parameters in this guideline that can be used for these processes, if using FSIS guidance as scientific support, see Table 5. Scientific Gaps where Critical Operating Parameters From Older Guidance May be Used page 44. How is indirect heating identified? Moving air or steam is a sign of convective (indirect) heating. Ovens that use moving air to heat the product need to address relative humidity to ensure sufficient Log reductions for pathogens are achieved." "Do Products Cooked in Natural Casings Made from Animal Gastrointestinal Tracts Need to Address Relative Humidity? No, establishments using FSIS cooking guidance as support do not need to address relative humidity for products that are cooked in a natural casing, including products that are cooked and then dried.<sup>1</sup> Natural casings made from animal gastrointestinal tracts are typically considered permeable and many establishments take advantage of their permeability to produce dried products or smoked products. However, depending on how they are used, the permeability of natural casings may be reduced. Most cooking processes likely reduce the permeability of natural casings early in the process so that humidity around the product is inherently maintained throughout the remainder of cooking and does not have to be added or monitored. According to Sebranek, (2010), establishments will apply smoke early in the process while the casing is still moist and permeable to the smoke. Prior to smoke application, the casing surface should be \"tacky\" or \"sticky.\" After smoke deposition and color development, further cooking denatures the proteins in the casing reducing permeability to the point that later cooking can be applied without great moisture loss from the product. Proteins in natural casings begin denaturing at 126°F (Tornberg, 2005). However, most drying processes use lower temperatures and address relative humidity to maintain casing permeability so that moisture can evaporate from the product during drying. Although most cooking processes likely result in reduced permeability of natural casings early in the cooking process, little research has been performed to study the critical operating parameters that impact the reduction of permeability such as the length of the initial smoke application step, cooking temperature, total cooking time, use of steam, size of casings, composition of sausage batter, etc. For this reason, FSIS has posted a research study on its website to determine if natural casings maintain sufficient

moisture to ensure product lethality using Appendix A time and temperature tables.\u201d Without this additional research, the Log reduction of Salmonella is less certain if meat products in natural casings are cooked using one of the timetemperature parameters in this FSIS cooking guidance without following one of the humidity options. So, while FSIS has indicated establishments using FSIS cooking guidance as support do not need to address relative humidity for products that are cooked in a natural casing, if an establishment uses one of the time-temperature parameters in FSIS cooking guidance without addressing relative humidity has a positive Salmonella test result through FSIS or its own testing, it should, as part of corrective actions, provide evidence that lack of relative humidity was not the cause. In addition, if research is completed and data becomes available that indicates relative humidity needs to be addressed when products are cooked in a natural casing, FSIS may change its recommendation. 1NOTE: As described in the Products and Processes Not Covered by This Guidance, this guideline is not appropriate support for lethality of a process that relies on drying alone or to support a process where the drying step comes before a cooking step that does not apply humidity or does not apply humidity during cooking at sufficient levels to rehydrate the product surface during the cooking step under dry conditions.", "34 Endpoint Time-Temperature FSIS time-temperature tables in this guideline (Meat Table, the 5-Log Table, and the Poultry Time-Temperature Tables) list internal product temperatures and the corresponding dwell times needed to achieve specific Log reductions of Salmonella. These tables may be used as scientific support to ensure that the process meets regulatory requirements (see General Considerations for Designing HACCP Systems to Achieve Lethality by Cooking, page 18). NOTE: To apply an alternative lethality and use Table 6. Time-Temperature Combinations for Meat Products to Achieve a 5-Log Reduction (page 59), an establishment must provide additional documentation showing that the product meets the performance standard (if applicable) and that potentially hazardous pathogens have been controlled (see Attachment A1. Customized Processes and Alternative Lethality Support subsection: Supporting an Alternative Lethality Target (e.g., 5-Log) on page 57). The support should demonstrate the incoming load of Salmonella is lower than FSIS estimated based on its baseline studies, and therefore, a lower reduction from cooking would result in no viable Salmonella in the finished product. Key Question Question: When an establishment decides to use a FSIS time-temperature table (i.e., the 5-Log Meat Table, 6.5-Log Meat Table, or the 7.0-Log Poultry Time-Temperature Tables) from this guideline as its scientific support for its cooking\lethality step, can the establishment use the entire table as its critical limit in its HACCP plan? Answer: Yes, the establishment can use the entire table to comply with 9 CFR 417.2(c)(3). The establishment needs to make a sound determination and support its decision in selecting and monitoring the time-temperature parameter(s) it uses for its production (9 CFR 417.5(a)(2)). In addition, establishments must collect in-plant data for at least one product from each HACCP category demonstrating the implementation of the critical operational parameters of the scientific support (9 CFR 417.4(a)(1)). At a minimum, the establishment will need to demonstrate that it is able to consistently meet a specific time-temperature from the table identified during the initial validation period to support the cooking\lethality process is validated (9 CFR 417.4(a)(1)).", "35 Table 2. Time-Temperature Combinations for Meat Products to Achieve Lethality Temperatures stated are the minimum internal temperatures that must be met in all parts of the meat product for the total dwell time listed.5 An establishment must ensure both

time and temperature parameters are met to use this table to support its process achieves the Log reduction target. Relative humidity<sup>6</sup> and heating come-up-time (CUT)<sup>7</sup> are also critical operating parameters when using this table. (See pages 37 and 38 for poultry endpoint timetemperature tables). 5 The required Log reductions are achieved instantly (0 seconds) when the internal temperature of a cooked meat product reaches 158°F or above.<sup>6</sup> Time-Temperatures  $\geq 145^{\circ}\text{F}$  (in blue square) are eligible for FSIS Relative Humidity Options 1 and 2. All time-temperatures may apply FSIS Relative Humidity Options 3 and 4 (page 26). 7 FSIS recommends limiting the total time product temperature is between 50 and 130°F to 6 hours or less (see page 23).", "36 Additional Critical Operating Parameters for Poultry Products The following are additional critical operational parameters that should be considered when cooking poultry products using FSIS newer guidance in the poultry timetemperature tables. Note: The older poultry recommendations for Cooked Poultry Rolls on page 39 apply regardless of species or fat because these were not considered critical operating parameters at the time the recommendation was developed. FSIS is not aware of any outbreaks or food safety incidents as a result of applying these recommendations to products of varying species or fat level. Product Species Generally, FSIS accepts that research for an intervention's effectiveness on one species of poultry (i.e., chickens, turkeys, ducks, geese, ratites, and squabs) can be applied to another species of poultry without additional support (FSIS Directive 5000.6, Performance of the Hazard Analysis Verification Task). However, research by Juneja et al. (2001a) demonstrated that in cooking processes, *Salmonella* heat tolerance depends on the poultry species. Therefore, when FSIS developed its time-temperature tables for poultry it developed two unique poultry time-temperature tables: one for chicken (page 37), another for turkey (page 38). When making poultry products containing poultry species other than chicken or turkey, or products made with a mixture of poultry species, FSIS recommends selecting an endpoint temperature, then using the longest dwell time recommended for the product fat content and endpoint temperature in either the chicken or turkey table. Comparing the tables and using the longest recommended dwell time ensures the HACCP system is designed to address the worst-case scenario for *Salmonella* survival in the product. Products that are a mixture of poultry and meat must achieve a 7-Log reduction of *Salmonella* (see Key Question on page 19). Fat Content In the presence of fats, the heat tolerance of some microorganisms generally increases (Jay et al., 2000). This is sometimes referred to as fat protection and is presumed to increase heat tolerance by affecting cell moisture. Juneja et al., (2001b) showed that higher fat levels in beef result in increased heat resistance of *Salmonella*, which is in agreement with publications regarding other food borne pathogens (Line et al., 1991; Ahmed et al., 1995). The Poultry Time-Temperature Tables (pages 37 and 38) provide establishments with time-temperature combinations that can be used to cook chicken and turkey products with different fat levels.", "37 Table 3. Time-Temperature Combinations for Chicken Products to Achieve Lethality Times for given temperatures and fat levels that are needed to obtain a 7-Log reduction of *Salmonella* in chicken products.<sup>8</sup> As described on page 23, relative humidity<sup>9</sup> and heating come-up-time (CUT)<sup>10</sup> are critical operating parameters when using this table. 8 A 7-Log reduction of *Salmonella* is achieved instantly at internal temperatures in which the holding time is 0 seconds (0 sec.). 9 Time-Temperatures  $\geq 145^{\circ}\text{F}$  (in blue square) are eligible for FSIS Relative Humidity Options 1 and 2. All time-temperatures may apply FSIS Relative Humidity Options 3 and 4 (page

26). 10 FSIS recommends limiting the total time product temperature is between 50 and 130°F to 6 hours or less (see page 23).,"38 Table 4. Time-Temperature Combinations for Turkey Products to Achieve Lethality Times for given temperatures and fat levels that are needed to obtain a 7-Log reduction of Salmonella in turkey products.11 As described on page 23, relative humidity<sup>12</sup> and heating come-up-time (CUT)<sup>13</sup> are critical operating parameters when using this table. 11 A 7-Log reduction of Salmonella is achieved instantly at internal temperatures in which the holding time is 0 seconds (0 sec.). 12 Time-Temperatures <sup>14</sup> 145°F (in blue square) are eligible for FSIS Relative Humidity Options 1 and 2. All time-temperatures may apply FSIS Relative Humidity Options 3 and 4 (page 26). 13 FSIS recommends limiting the total time product temperature is between 50 and 130°F to 6 hours or less (see page 23).,"39 Cooked Poultry Rolls Options FSIS recommends establishments use the options in the Poultry Time-Temperature Tables (page 37 and 38) (which include dwell times at 160°F that vary based on fat content and species) because they have been validated with updated research to address species and fat content as critical operating parameters to ensure adequate Log reductions of Salmonella. However, FSIS is including the two older options below for cooking poultry rolls and other poultry products because they still may be used by some establishments. Applying the cooked poultry rolls options below may achieve the same Log reductions as the time-temperature combinations in the Poultry TimeTemperature Tables, particularly when applied to a lean product, because the product may be maintained at 160°F for the recommended dwell times (between 13.7 to 26.9 seconds depending on species and fat) during the time it takes to complete temperature monitoring. Regardless, FSIS recommends establishments monitor the dwell time in the Poultry Time-Temperature Tables as opposed to relying on the older guidance for cooked poultry rolls below to better assure safety. The options below can be applied to any poultry product (not just cooked poultry rolls) regardless of fat content or poultry species. However, if FSIS collects a RTE sample that is positive for Salmonella or if the establishment is implicated in a food safety investigation related to Salmonella (i.e., is associated with reports of illness or outbreak), FSIS will review and determine the adequacy of the establishment's required corrective actions (taken under 9 CFR 417.3), to address process deviations. The establishment will need to show FSIS that inadequate lethality was not the root cause of the process deviation if it wants to continue to follow the cooked poultry rolls options. To use a cooked poultry rolls option, the establishment must address all critical operating parameters for cooking identified in this guideline (other than species or fat), including relative humidity (page 26) and CUT (page 23). 1. Cooked poultry rolls and other cooked poultry products must reach an internal temperature of at least 160°F (instantaneous) during the cooking process. 2. Cured and smoked poultry rolls and other cured and smoked poultry must reach an internal temperature of at least 155°F (instantaneous) during the cooking process. Key Question Question: Can establishments that produce poultry products with higher than 12% fat use values for 12% fat in the Poultry Time-Temperature Tables? Answer: Yes. The time-temperature combinations listed in the tables for poultry products with 12% fat can be used for products with higher percentages of fat and for products with unknown fat content. These time-temperature combinations will achieve sufficient lethality as long as adequate humidity (FSIS Relative Humidity Options page 26) is applied during the process.","40 Resources for Customized and Alternative Support FSIS recognizes that not all meat and poultry products can be cooked using

the FSIS critical operating parameters (humidity, CUT and endpoint time-temperature) included in this guideline. To assist establishments in cooking their products, FSIS has identified additional resources which may provide scientific support for a specific process or part of a process. Attachment A1. Customized Processes and Alternative Lethality Support includes information on the following:

- \u2022 Alternative Lethality Target: Under certain circumstances and with additional support, establishments may be able to use an alternative lethality target (e.g. 5Log). See Attachment A1. Supporting an Alternative Lethality Target, page 57 of this guideline.
- \u2022 Journal Articles: Establishments could identify a published journal article which shows a specific process meets the performance standard and use this as scientific support. See Attachment A1. Common Topics and Journal Articles Used for Alternative Support page 60 of this guideline.
- \u2022 Customized Cooking Schedule: Establishments may design a customized cooking plan using validated microbial models. See Attachment A1. Predictive Microbial Modeling for Critical Operating Parameters, page 62 of this guideline.
- \u2022 Challenge Studies: Establishments could conduct challenge studies to determine if their proposed process would meet the performance standard. See Attachment A1. Designing Challenge Studies for Cooking, page 63 of this guideline.

In addition to information for developing customized critical operating parameters, this guideline contains additional resources, listed below, to address common questions and issues establishments may have regarding cooking of meat and poultry products.

- \u2022 Pasteurized Label: Establishments may be able to label their cooked meat or poultry product as \u201cPasteurized.\u201d See Attachment A3. When can Products be Labeled as Pasteurized?, page 81 of this guideline.
- \u2022 Common Sources of Salmonella: Salmonella contamination may occur on cooked products for a variety of reasons. For information on sources of Salmonella contamination and Best Practices to implement to address it, see Attachment A4. Sources of Salmonella Contamination in RTE Products and Best Practices to Address It page 82 of this guideline.
- \u2022 Ready-to-eat (RTE) Self-Assessment Tool: FSIS has included a self-assessment tool that establishments can use to identify areas in their process where they could improve Salmonella control. See Attachment A5. RTE Salmonella Self-Assessment Tool page 87 of this guideline.

"41 Scientific Gaps Identified by FSIS FSIS has identified several common cooking processes that can\u2019t achieve the critical operating parameters included in this guideline. FSIS encourages establishments to conduct challenge studies when other support is not available (page 63). However, the Agency realizes it may not be cost effective for establishments to conduct individual challenge studies for commonly produced meat and poultry products. To address these common processes, which lack readily available scientific support, FSIS has identified and communicated scientific gaps and is working to facilitate filling these gaps. FSIS posted research priorities on its website to communicate clear research needs with USDA Agricultural Research Service (ARS) and academic researchers. As additional data becomes available, FSIS will update the recommendations for these scientific gaps with the latest available scientific support. An establishment producing products using processes that fall under an identified scientific gap may use the critical operating parameters in this guideline as scientific support (see Table 5. Scientific Gaps where Critical Operating Parameters From Older Guidance May be Used page 43). Table 5 also describes specific vulnerabilities with using the gaps as scientific support and recommends steps to reduce the vulnerabilities. In addition to those specific vulnerabilities, FSIS has the following concerns with establishments continuing to

process products using the critical operating parameters in Table 5: \u2022 Use of these critical operating parameters represents a vulnerability because these processes have not been validated to address all hazards of concern. The original research used to develop these critical operating parameters was performed on only the few products covered by the performance standard to be included in the 1999 version of Appendix A [64 FR 732]. \u2022 If a process deviation occurs for a process that is included as a scientific gap, it is unlikely an establishment would be able to identify adequate support for product safety without performing product testing. \u2022 If FSIS or the establishment collects a ready-to-eat (RTE) sample that is positive for Salmonella, or the establishment is implicated in a food safety investigation related to Salmonella (i.e., is associated with reports of illness or outbreak), FSIS would verify, as part of the corrective actions (9 CFR 417.3), that the establishment can support inadequate lethality was not the root cause, if it wants to continue to use the older recommendation. \u2022 As additional data becomes available, FSIS will change the recommendations for processes that fall under one of these scientific gaps.","42 NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps.

Additionally, Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical operating parameters listed in Table 5. FSIS will update this guideline as more research becomes available and new options can be developed. Scientific gaps are processes which have not been validated to achieve sufficient lethality and to address all potential hazards during cooking, but establishments may continue to use this guidance as support to allow additional time for research to be conducted and gaps filled.","NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 5).

43 Table 5. Scientific Gaps where Critical Operating Parameters From Older Guidance May be Used Gap Examples of Products 1999 Critical Operating Parameters Vulnerability with Continuing to Follow 1999 Parameters 1. Products cooked for short times at high temperatures that cannot maintain 90% humidity per Option 4 and do not meet the Situations when Humidity is Not Needed (page 31). Processes that meet this gap include those in which product is: \u2022 Cooked for less than 1 hour, at dry bulb oven temperatures above 212\u00b0F. NOTE: Above 212\u00b0F the maximum relative humidity decreases as the temperature increases making it impossible to achieve 90% relative humidity in the oven regardless of the amount of moisture present. Cooking meatballs or poultry tenders using impingement, spiral, and steam-injected inline ovens. NOTE: Jerky products are not included under this gap. There are many validated lethality processes available for jerky products. Apply FSIS timetemperature tables (pages 35, 37, 38), addressing all critical operating parameters (page 23) except relative humidity. NOTE: Relative humidity does not need to be addressed for products cooked in completely immersed in water (page 31). These parameters may allow the surface of the product to dry out during cooking. Lack of humidity can cause pathogens to develop heat tolerance and allow them to survive the heating process. In addition, shorter cooking processes allow for limited additional lethality during the heating comeup time (sometimes called cumulative or integrated lethality) which reduces the safety margin the process provides. To minimize these vulnerabilities, an establishment may choose to implement, validate, and monitor as part of the HACCP system, any of the following to ensure moist cooking and demonstrate surface lethality:

- o Wet-bulb

temperature. o Dew point temperature. o Percent moisture by volume. o Increase dwell time or endpoint temperature. o Increase total cooking time to increase integrated lethality. Or perform a challenge study (page 63). Or conduct finished product testing for Salmonella as part of on-going verification.", "NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 5). 44 Gap Examples of Products 1999 Critical Operating Parameters Vulnerability with Continuing to Follow 1999 Parameters 2. Products cooked using microwave cooking methods that are not designed to control relative humidity. Processes that meet this gap include those in which a meat or poultry product is cooked using a continuous or non-continuous microwave oven. Sliced bacon or bacon chips cooked using continuous microwave ovens. Apply FSIS timetemperature tables (pages 35, 37, 38), addressing all critical operating parameters (page 23) except relative humidity. These parameters may not ensure surface lethality. In addition, shorter cooking processes allow for limited additional lethality during the heating come-up time (sometimes called cumulative or integrated lethality) which reduces the safety margin the process provides. To minimize these vulnerabilities, an establishment may choose to implement, validate, and monitor, any of the following to ensure moist cooking and demonstrate surface lethality: o Increase dwell time or endpoint temperature. o Increase total cooking time to increase integrated lethality. Or perform a challenge study (page 63). Or conduct finished product testing for Salmonella as part of on-going verification. NOTE: There is an additional vulnerability with microwave cooking that the microwave energy may not result in lethality of pathogens on continuous belt surfaces (Taormina et al., 2011).", "NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 5). 45 Gap Examples of Products 1999 Critical Operating Parameters Vulnerability with Continuing to Follow 1999 Parameters 3. Products cooked using cooking methods that are not designed to control relative humidity other than microwave ovens. Processes that meet this gap include those where product is either: \u2022 Cooked in ovens that are not designed to be sealed (e.g., no dampers) and designed without a mechanism to introduce steam. Or \u2022 Barbecue products cooked under dry heat to meet labeling requirements (e.g., 9 CFR 319.80; and 9 CFR 381.164). NOTE: This does not include smokehouses where the gaskets or dampers are broken or have been removed. Rotisserie chicken Products such as pork butt or beef brisket cooked using restaurant or foodservice type convection ovens. Barbecue products cooked under dry heat including those cooked in smokehouses or open pits. NOTE: Jerky products are not included in this gap. There are many validated lethality processes available for jerky products. Apply FSIS timetemperature tables (pages 35, 37, 38), addressing all critical operating parameters (page 23) except relative humidity. NOTE: Relative humidity does not need to be addressed for products 10 pounds or more cooked in an oven at 250\u00b0F or higher (page 31). These parameters may allow the surface of the product to dry out during cooking. Lack of humidity can cause pathogens to develop heat tolerance and allow them to survive the heating process. To minimize this vulnerability, an establishment may choose to implement, validate, and monitor, any of the following to ensure moist cooking and demonstrate surface lethality: o Wet-bulb temperature.

o Dew point temperature. o Percent moisture by volume. Depending on the process, pans of water may be added to increase moisture in the cooking chamber. Or perform a challenge study (page 63). Or conduct finished product testing for Salmonella as part of on-going verification." , "NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 5). 46 Gap Examples of Products 1999 Critical Operating Parameters Vulnerability with Continuing to Follow 1999 Parameters 4. Other processes that may inherently maintain relative humidity around the meat and poultry filling but cannot follow one of the relative humidity options. Processes that meet this gap include those that involve: \u2022 Use of an edible wrapping that fully encloses a raw meat or poultry filling before cooking. Example wrappings include: o dough, o leaves, and o edible rice paper. NOTE: Products cooked in a natural casing are not included in this gap, since FSIS includes natural casing in Situations when Humidity is Not Needed (page 31). Baked pasties, empanadas, pot-stickers, and dumplings. Apply FSIS timetemperature tables (pages 35, 37, 38), addressing all critical operating parameters (page 23) except relative humidity. These parameters may allow the surface of the filling or wrapping to dry during cooking. Lack of humidity can cause pathogens to develop heat tolerance and allow them to survive cooking. To minimize this vulnerability, an establishment may choose to implement, validate, and monitor as part of the HACCP system, any of the following to ensure sufficient lethality on the outside and inside of the wrapped products: o Cook filling first. o Measure water activity of filling before and after cooking to support moisture is inherently maintained (water activity stays the same or increases after cooking). FSIS recommends establishments achieve the highest water activity possible during cooking. Values \u2265 0.96 have been shown to prevent pathogen heat tolerance, but this water activity may not be possible to achieve for all processes (Kieboom, et al. 2006). o Cook to a higher endpoint temperature than the FSIS time-temperature tables, to compensate for the low humidity conditions. Or perform a challenge study (page 63). Or conduct finished product testing for Salmonella as part of on-going verification." , "NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 5). 47 Gap Examples of Products 1999 Critical Operating Parameters Vulnerability with Continuing to Follow 1999 Parameters 5. Processes where the drying step comes before cooking under moist conditions. Processes that meet this gap include those in which products are: \u2022 Dried to reduce the water activity and then cooked using one of the following options that ensures high relative humidity o Option 1, or o Option 3, or o Option 4, or o Cook-in-bag, or o Immersion cooking. NOTE: This gap does NOT apply products cooked after drying without applying relative humidity (e.g., cooking under dry conditions or direct heat), or to dried products cooked multiple times. It is not supportable for dried products to apply direct heat instead of addressing relative humidity, without additional support for surface lethality (page 31). Country-cured hams that are cooked-in-bag one time. Soups that have a reduced water activity due to a high salt concentration but are a liquid medium. NOTE: Jerky products are not included in this gap. There are many validated lethality processes available for jerky products. Apply: FSIS timetemperature tables (pages 35, 37, 38), addressing all critical operating parameters (page

23) and use relative humidity: o Option 1, or o Option 3, or o Option 4, or o Cook-in-bag, or o Immersion cooking. NOTE: FSIS does not consider a sealed oven (Option 2) to be adequate support that the surface of the product is rehydrated during cooking of reduced water activity products. There is a vulnerability if pathogens develop heat tolerance during drying which could allow them to survive the cooking process. To minimize this vulnerability, an establishment may choose to implement, validate, and monitor as part of the HACCP system, any of the following to ensure sufficient moisture during cooking: o Take water activity measurements of the surface of the product before and after cooking to support the surface is rehydrated (water activity increases after cooking). o Achieve the highest water activity possible during cooking. Values  $\leq 0.96$  have been shown to prevent pathogen heat tolerance, but this water activity may not be possible to achieve for all processes (Kieboom, et al. 2006). Or perform a challenge study (page 63). Or conduct finished product testing for Salmonella and Lm as part of on-going verification. Additional recommendations are included in Attachment A6. Cooking Country-Cured Hams on page 90." , "NOTE: Scientific gaps only affect very specific products and processes. Process deviations and malfunctioning equipment are NOT scientific gaps. Products and Processes Not Covered by this Guideline would NOT be adequately supported by the critical parameters listed in scientific gaps (Table 5). 48 Gap Examples of Products 1999 Critical Operating Parameters Vulnerability with Continuing to Follow 1999 Parameters 6. Products with long heating come-up-times (CUTs). This gap applies to processes that require a: \u2022 Heating come-up-time longer than 6 hours (page 23). NOTE: See page 62 for references supporting longer CUTs for fully cooked products formulated with antimicrobials to inhibit S. aureus that are cooked to lethality. Ham and beef brisket. NOTE: Drycured or immersion cured products produced under this Cooking Guideline Scientific Gap may also be produced under a Stabilization Guideline Scientific Gap if formulated without erythorbate or ascorbate. Apply any of FSIS\u2019s applicable timetemperature combinations (pages 35, 37, 38) and relative humidity, without considering CUT as a critical operating parameter. NOTE: For intact products, establishment may be able to monitor the surface temperature to allow for longer CUTs, instead of addressing this gap (page 24). A vulnerability exists in that S. aureus may grow to levels that result in the production of a heatstable enterotoxin if CUTs are longer than 6 hours without the use of antimicrobials. To minimize this vulnerability, an establishment may choose to implement, validate, and monitor as part of the HACCP system, any of the following to ensure S. aureus outgrowth is limited: o Critical parameters from a published journal article that supports extending the come-up-time in products and processes. (page 62). o Reduce product diameter to reduce CUT. o Conduct predictive pathogen modeling for a particular product and process (page 55). o Limit CUT between 50  $\leq 130\text{ }\mu\text{F}$  and set a defined limit based on the shortest CUT possible for the establishment\u2019s specific process. o Apply smoke, which may inhibit S. aureus and C. perfringens growth. Or perform a challenge study (page 63). Or conduct finished product verification testing for S. aureus enterotoxins (page 77); or", "49 References Ahmed, M.N., Conner, D.E. and Huffman, D.L. 1995. "55 Attachment A1. Customized Processes and Alternative Lethality Support Following FSIS Critical Operating Parameters for Cooking (Time-Temperature Tables) (page 23) will yield product that meets the lethality performance standards and targets. However, some establishments may want to develop customized processing procedures to achieve lethality. Establishments or their process authorities may develop customized processes or an alternative lethality that meets the performance standards or targets by using information obtained from the literature or by comparing their processes with established processes. However, all processes must achieve a supported Log reduction of pathogens and prevent the production of toxins or toxic metabolites (e.g., *Staphylococcus aureus*) to meet HACCP requirements and produce safe food (General Considerations for Designing HACCP Systems to Achieve Lethality by Cooking, page 18). Regardless of the scientific support used, the establishment's actual process must match the critical operating parameters in the scientific support in order to achieve adequate lethality and meet validation requirements. In addition to the recommendations provided in the HACCP Systems Validation Guideline, FSIS recommends that establishments and processing authorities address the following questions when evaluating how journal articles and other sources of alternative support may apply to a cooking process:

1. Does the scientific support (e.g., book chapters,

journal articles) demonstrate that sufficient lethality of Salmonella (or a supported surrogate) is achieved in the product? o Negative results obtained from finished product sampling alone (without inoculation) are not sufficient to demonstrate that the product meets the performance standards or targets because they do not support any particular reduction in pathogens is achieved by the process. o Studies should evaluate the survival of a mixture (cocktail) of Salmonella, including strains associated with human illness and strains isolated from meat and poultry products. Ideally, some of the strains selected should be those with known heat-tolerance properties.

2. Does the scientific support identify all critical operating parameters used to achieve lethality (e.g., relative humidity)? o Many research studies designed to determine D-values of pathogens in different food matrices use enclosed systems that maintain moisture, such as sealed glass tubes, or impermeable bags immersed in hot water. These studies, as published in journal articles, may not specifically list controlling moisture during cooking as a critical operating parameter, but the methods used inherently maintain moisture in the system. To achieve", "56 the same result as the study, an establishment would need to consider how its process will apply moisture to ensure lethality on the product surface during cooking (see page 16).

Acceptability of Challenge Study Results

There are different ways to evaluate the results of challenge studies and scientific literature, such as journal articles. The National Advisory Committee on Microbiological Criteria for Foods (NACMCF), in its 2010 article \u201cParameters for Determining Inoculated Pack\u201d\Challenge Study Protocols\u201d recommends a statistical analysis be performed on results or, if not, a clear justification be provided. Below are three acceptable ways to determine if the results of the research are sufficient to support an establishment\u2019s lethality process:

1. The mean (average) is \u2265 performance standard or target log reduction.
2. Results for all replicates are \u2265 performance standard or target.
3. The lower 95% confidence limit for the results from the study is \u2265 performance standard or target.

o What this means is the reduction is calculated based on the mean log reduction minus 1.94 times the standard deviation. The recommendation to subtract 1.94 times the standard deviation from the mean log reduction is based on a study with an n of 6 (i.e., three replicates and two samples per replicate or two replicates and three samples per replicate). The approaches are listed in order of increasing confidence the results support an acceptable lethality process. The first approach (using the mean or average result) provides the least confidence the lethality process will consistently achieve the performance standard or target because it does not take into account variation found in the results. The third approach (using the lower 95% confidence limit) provides the greatest confidence but is also the most conservative because it takes into account a confidence interval based on variation found during the study.", "57 Supporting an Alternative Lethality Target (e.g., 5-Log) Establishments that use an alternative lethality (e.g., FSIS 5-Log Table) need to consider a number of factors that were identified in the Salmonella risk assessment, specifically: \u2022 Product categorization (shelf-stable or not shelf-stable). \u2022 Pathogen load in raw materials. \u2022 Storage and growth. \u2022 Consumer reheating. How is Alternative 5-Log Lethality Related to Risk of Foodborne Illness? Historically, FSIS has recommended that establishments achieve at least a 6.5-Log reduction of Salmonella in cooked meat products (other than beef patties which require a 5-Log reduction). The previous recommendations were due to the Risk Assessment of the Impact of Lethality Standards on Salmonellosis from RTE Meat and Poultry Products, 2005 (Salmonella Risk

Assessment), which showed that a 5Log reduction of Salmonella (instead of a 6.5-Log reduction) would result in a greater risk of illness in cooked meat products. The regulations for cooked beef, corned beef, and roast beef in 9 CFR 318.17(a)(1) allow for the use of alternative lethality, provided it provides equivalent probability that no viable Salmonella cells remain in the finished product, as well as ensures the reduction of other pathogens and their toxins or toxic metabolites necessary to prevent adulteration. FSIS is providing guidance to establishments regarding how to validate the alternative lethality option of achieving at least a 5-Log reduction of Salmonella in cooked meat products other than beef patties to ensure the lower reduction does not result in a greater risk of illness. For shelf-stable products, that primarily rely on means other than cooking to achieve lethality, the Salmonella Risk Assessment did not show a substantially higher risk of illness for product with a 5Log reduction compared to a 6.5-Log reduction, so FSIS continues to recommend a 5-Log reduction of Salmonella for shelf-stable products. Therefore, establishments do not need to provide additional support for decisions in the hazard analysis (9 CFR 417.5(a)(1)) if they identify a 5-Log reduction of Salmonella as the lethality target for shelf-stable.", "58 An establishment can use the following bulleted options to support an alternative lethality target. The alternative lethality target may be from alternative supporting documentation (Attachment A1. Customized Processes and Alternative Lethality Support page 55) or with the time-temperature combinations in Table 6. TimeTemperature Combinations for Meat Products to Achieve a 5-Log Reduction (page 59). \u2022 Use source materials that have been tested or treated to reduce pathogens. The establishment can use a cooking process that achieves a 5-Log lethality of Salmonella if it uses source materials that have been tested or treated to reduce pathogens. The establishment should maintain support (e.g., Letters of Guarantee (LOG), Certificates of Analysis (COA), or sampling information) for each lot demonstrating that the levels of Salmonella are low enough to be controlled by a process achieving 5-Log reduction with an appropriate safety margin (e.g., 2-Log). For example, an establishment may provide a LOG indicating that a certain Log reduction (e.g., 1.5-Log or 2-Log) is achieved in the source materials using a validated antimicrobial intervention. \u2022 Conduct a Salmonella baseline study on the raw source material. The baseline study should be designed such that the establishment can demonstrate, with reasonable confidence, that less than 0.01% of the raw, formulated product contains concentrations > 10 CFU\gram of Salmonella before cooking. This is based on the premise that a 5-Log lethality step would reduce a Salmonella level of < 10 CFU\gram to < 1 CFU\ 100 grams and provide a 2-Log margin of safety (NACMCF, 2010). Challenges Supporting a 5-Log Alternative Lethality for Cooked Beef Products FSIS recognizes that extensive baseline sampling and testing needed to apply a 5-Log lethality may be cost prohibitive for small and very small establishments. However, this document provides multiple options for meeting the performance standards for certain RTE products. As noted in the question box above, establishments do not need additional testing or support to apply the 6.5-Log Meat Table, or the 7.0-Log Poultry Time-Temperature Tables in their process. Key Question Question: Do establishments that want to use the 6.5-Log Time-Temperature Tables need to perform raw product testing or provide other support? Answer: No. The times and temperatures listed in the tables for 6.5-Log or 7.0-Log reductions can be used without any additional support or testing. These time-temperature combinations will achieve sufficient lethality as long as adequate humidity (page 26) is applied during the process.", "59 Table 6. Time-Temperature

Combinations for Meat Products to Achieve a 5-Log Reduction Temperatures stated are the minimum internal temperatures that must be met in all parts of the product for the total dwell time listed<sup>14,15</sup>. An establishment must ensure both time and temperature parameters are met to use this table to support that its process achieves a 5-Log reduction of Salmonella. As described on page 23, relative humidity<sup>16</sup> and heating comeup-time (CUT)<sup>17</sup> are critical operating parameters when using this table. 14 A 5-Log reduction of Salmonella is achieved instantly (0 seconds) when the internal temperature of a cooked meat product reaches 158°F or above. 15 When using this table for not shelf-stable products other than meat patties, establishments must provide additional support to show why a 5-Log reduction is sufficient to ensure pathogens are eliminated (Supporting an Alternative Lethality Target (e.g., 5-Log) page 50). 16 Time-Temperatures 122-145°F (in blue square) are eligible for FSIS Relative Humidity Options 1 and 2. All time-temperatures may apply to FSIS Relative Humidity Options 3 and 4 (page 26). 17 FSIS recommends limiting the total time product temperature is between 50 and 130°F to 6 hours or less (see page 23).<sup>18</sup>

**60 Common Topics and Journal Articles Used for Alternative Support**

Many journal articles have been published that have increased scientific understanding of the critical role of certain operating parameters during cooking including relative humidity. FSIS recognizes that many of these journal articles, including that by Buege et al., (2006), support the use of less than 90% relative humidity (FSIS Relative Humidity Option 4; page 26). Establishments may use these journal articles as scientific support as long as establishments ensure the published critical operating parameters match the critical operating parameters being used in the establishment's process. FSIS agrees that wet-bulb temperature is a good indicator of surface lethality during cooking but does not believe there is enough information at this time to make a general recommendation that a single wet-bulb temperature can be used in place of the FSIS relative humidity options for all products. For more information see FSIS' wet-bulb video available at: <https://youtu.be/as-c2bCsoHQ>. Other commonly used alternatives to relative humidity include dew point temperature and percent moisture by volume. Alternative measures are particularly valuable in products cooked at high dry bulb temperatures. However, at this time, there is no consensus or scientifically supported recommendation for how to use those parameters or a targeted value to reach for each parameter. Consequently, FSIS has posted an FSIS research priority on its website and is aware that researchers are actively investigating this issue (Scientific Gaps Identified by FSIS page 41). Journal articles or reports establishments may consider using as scientific support, grouped by topic area, include:

- o 2022 Validated cook schedules for making beef jerky by controlling dry bulb and wet bulb temperatures.
- o Buege, D.R., Searls, G., Ingham, S.C. 2006. Lethality of commercial whole-muscle beef jerky manufacturing processes against *Salmonella* serovars and *Escherichia coli* O157: H7. *Journal of Food Protection*. 69(9):2091-2099.

NOTE: Establishments may use this final report as scientific support until a peer-reviewed journal article is published. CUT Option FSIS\u2019s CUT option (page 23) was developed to support a wide variety of products. It is designed to use product characteristics that would allow the most *S. aureus* growth (worst-case scenario). Using worst-case conditions ensures that the option prevents *S. aureus* from being a hazard in all products. Establishments may be able to identify Why do some journal articles support using different critical operating parameters for cooking than those recommended by FSIS? FSIS guidance is designed to ensure lethality for a large number of meat and poultry products across broad product categories. Research on specific processes and product types may support adequate lethality can be achieved using different critical operating parameters for certain products (e.g., shorter dwell time or lower endpoint temperature), but research is not always available to support using those parameters across the many product categories and product types that this guidance covers. Establishments may choose to follow journal articles or other peer-reviewed scientific data instead of FSIS guidance, provided the same critical operating parameters are met (e.g., product type, dry-bulb temperature, wet-bulb temperature, internal product temperature, and intrinsic factors) and the process achieves sufficient reductions for *Salmonella* based on the establishment\u2019s desired target." , "62 journal articles with longer CUT for products with specific characteristics that inhibit pathogen growth (e.g., formulated with antimicrobials like sodium lactate). Example: \u2022 This following journal article provides critical limits for the brine injection and the thermal process that control *S. aureus* growth and enterotoxin production during a 14-hour CUT. o Ingham, S.C., Losinski, J.A., Dropp, B.K., Vivio, L.L., Buege, D.R. 2004. Evaluation of *Staphylococcus aureus* growth potential in ham during a slow-cooking process: use of predictions derived from the US Department of Agriculture Pathogen Modeling Program 6.1 predictive model and an inoculation study. *Journal of food protection*, 67(7):1512-1516. [https://meathaccp.wisc.edu/validation/heat\\_treatment.html](https://meathaccp.wisc.edu/validation/heat_treatment.html). \u2022 This following journal article provides critical operating parameters for hams formulated with phosphate and cooked to lethality while applying a long CUT. o Sindelar, J., Glass, K., Hanson, R., Sebranek, J.G., Cordray, J., Dickson, J.S. 2019. Validation for lethality processes for products with slow CUT: Bacon and bone-in-ham. *Food Control*. 104:147-151. NOTE: Although Sindelar et al. (2019) contains information on the growth of pathogens during the heating CUT for partially

heat-treated bacon, the article is not adequate sole support for controlling the growth of *C. perfringens* and *C. botulinum*. Please review the FSIS Stabilization Guideline for Meat and Poultry Products for additional details. Predictive Microbial Modeling to Support CUT Alternatively, establishments may use predictive microbiology modeling to develop custom critical operating parameters. Predictive food microbiology uses models (i.e., mathematical equations) to describe the growth, survival, or inactivation of microbes in food systems from knowledge of the intrinsic and extrinsic factors of the food over time. There are many free predictive microbial models available to establishments either online or through a download. Please refer to Predictive Microbial Modeling (page 72) for FSIS recommendations on using predictive microbial models to evaluate *S. aureus* growth during heating CUT deviations. These same recommendations can be applied when validating a custom CUT for a HACCP system.<sup>63</sup> Designing Challenge Studies for Cooking One of the most definitive tools at the disposal of an establishment or processing authority for validating a process is the challenge study. As stated in the HACCP Systems Validation Guideline, establishments may perform challenge (or inoculated pack) studies to provide scientific support for their processes. These studies are performed in a laboratory or pilot plant by a processing authority or expert. The documentation on file should specify the level of pathogen reduction, elimination, or growth control; describe the process, including all critical operating parameters affecting the reduction or elimination of the pathogen of concern; and give the source of the documentation. Such studies are often not published in peer-reviewed journal articles but should contain the same level of detail as is provided for peer-reviewed studies. Challenge studies should be designed and conducted to accurately simulate the commercial process. Challenge studies should be undertaken by individuals who have a thorough knowledge of laboratory methods used in *Salmonella* research. Challenge studies should be based on a sound statistical design (i.e., a statistical design that ensures confidence in the data) and should also employ positive and negative controls. The statistical design should include the number of samples collected at each time interval and the number of study replicates needed to ensure the validity of the study. There are quantitative methods for assessing the statistical quality of a study (e.g., power analysis). As per the National Advisory Committee on Microbiological Criteria for Foods (NACMCF), the minimum number of samples to be analyzed initially and at each time interval during processing or storage should be at least two. However, NACMCF highly recommends analysis of three or more samples at each time interval. According to NACMCF, challenge studies should include replicates. Replicates should be independent trials using different lots of product and inoculum to account for variations in product, process, inoculum, and other factors. When the number of samples analyzed at each time interval is only two, NACMCF suggests it is better for the study to be repeated (replicated) more than two times. In studies with three or more samples tested at each time interval, two replicates are usually adequate. A cocktail of various serotypes of *Salmonella* should be used in an inoculated pack study to demonstrate that the lethality performance standard or target is met. At least five strains of the pathogen should be used in the inoculum. Relatively heat tolerant pathogenic strains should be included in the cocktail to develop a worst case. The serotypes\strains selected should be among those that have been historically implicated in an appreciable number of outbreaks. FSIS does not require establishments to validate that their process achieves a specific reduction of STEC or Lm in cooked product if they achieve sufficient reductions of *Salmonella* because FSIS considers

Salmonella an indicator of lethality for cooked products. Without further scientific support, establishments should not use pathogens other than Salmonella as indicators of lethality. For example, establishments should not", "64 use reductions in L<sub>m</sub> to support similar reductions in Salmonella without support that L<sub>m</sub> is at least equally as heat tolerant as Salmonella under the conditions being studied. If an establishment chooses to conduct a challenge study in a testing laboratory, the study should use at least five strains of Salmonella, including strains associated with human illness and strains isolated from meat and poultry products. Ideally, some of the Salmonella strains selected should be those with known heat-tolerance properties. FSIS recommends that establishments and their laboratories include a justification for the strains chosen (e.g., associated with human illness or isolated from meat or poultry products) in the challenge study report. In addition, the inoculum level should be at least 2-Log greater than the Log reduction to be demonstrated. FSIS recommends that establishments use Salmonella as an indicator of lethality (Goodfellow and Brown, 1978; Line et al., 1991) or an appropriate surrogate of Salmonella that has similar heat and drying-tolerance properties. For example, Enterococcus faecium has been validated as a suitable surrogate for Salmonella during cooking of ground beef (Ma et al., 2007). FSIS considers all Salmonella serotypes to be pathogens of public health concern. At a minimum, a study for a microbiological food safety hazard should identify: \u2022 The hazard (including the specific strains studied). \u2022 The expected level of hazard reduction or prevention to be achieved. \u2022 The processing steps that will achieve the specified reduction. \u2022 All critical operating parameters or conditions (e.g., time, temperature, and humidity) necessary to achieve the reduction. \u2022 Procedures to monitor the critical operating parameters or conditions. \u2022 The critical ingredients (e.g., concentration of salt, sugar, and cure). \u2022 The critical product characteristics (e.g., pH, water activity, moisture level, and fat content). NOTE: For more information on conducting challenge studies, please review the article, \u201cParameters for Determining Inoculated Pack\u201d/Challenge Study Protocols,\u201d Key Question Question: Should a Challenge Study use S. Senftenberg 775W? Answer: Not necessarily. FSIS would not require that. The FSIS Jerky Guideline states, \u201cOne good [strain] choice, for example, might be Salmonella enterica serovar Senftenberg strain 775W, which displays heat resistance properties (Ng et al., 1969). Salmonella enterica serovar Senftenberg occurs in the top 10 serotypes seen in FSIS testing for both cow\u201d/bull carcass testing and ground beef, as well as in turkeys (carcass and ground) (FSIS testing data, 2012), so it would also be an appropriate choice for what might be seen in these products being tested.\u201d However, additional studies have determined that Salmonella Senftenberg has much higher heat tolerance than other pathogens (McMinn, et al., 2018; Veeramuthu, et al., 1998). In addition, more recent data does not continue to identify it in the top 10 serotypes seen in FSIS testing." "65 published by the NACMCF in the Journal of Food Protection in 2010. For more information on the use of positive and negative controls in challenge studies as well as general guidance on how to select a microbiological testing laboratory please review FSIS\u201dEstablishment Guidance for the Selection of a Commercial or Private Microbiological Testing Laboratory.", "66 Attachment A2. Cooking Deviations Corrective Actions to Perform When a Cooking Deviation Occurs Cooking deviations occur when an establishment fails to meet its cooking CCP critical limit for endpoint time-temperature, cooking humidity option, or heating come-up time option. Common causes for cooking deviations include product overlap, power failures, or breakdown of cooking equipment.

Establishments are required to take corrective actions, as required by the HACCP regulations, regardless of whether the cooking process is addressed through a CCP or prerequisite program. This includes ensuring no product that is injurious to health or otherwise adulterated because of the deviation enters commerce (9 CFR 417.3(a) or (b)). When cooking is addressed through a CCP, establishments are required to determine the cause of all cooking deviations, no matter how small (9 CFR 417.3(a)(1)), and ensure measures are established to prevent recurrence (9 CFR 417.3(a)(3)). If the cause of each small cooking deviation is not traced and corrected when first noticed, the problem will likely recur and become more frequent and more severe. The establishment should consider an occasional small process deviation to be an opportunity to find and correct a process control problem. Large process deviations or continual small ones always constitute unacceptable risk. Also, continual or repetitive process deviations from the critical limit demonstrate that the establishment is unable to control its process and that its corrective actions are not preventing recurrence as intended. When cooking is addressed through a prerequisite program and a deviation occurs, establishments are required to reassess their HACCP system to determine whether the newly identified deviation or unforeseen hazard should be addressed and incorporated into the HACCP plan (9 CFR 417.3(b)(4)). Also, an establishment may not be able to continue to support the decision in its hazard analysis that pathogens are not reasonably likely to occur, if it has continual or repetitive deviations from its cooking prerequisite program (9 CFR 417.5(a)(1)). To assist establishments in determining and supporting product disposition as required 9 CFR 417.3(a) or (b), FSIS is including information regarding potential pathogens of concern during different types of cooking deviations and recommendations for using pathogen modeling and sampling. Establishments should carefully evaluate each deviation as each situation is unique and needs to be evaluated individually. Ultimately, the establishment should rely on the expertise of a processing authority to determine the severity of cooking deviations and subsequent appropriate disposition of the product in question. Knowledge of the specific product and factors that would favor or inhibit the growth of various bacterial pathogens is essential to determine product safety. As stated in the HACCP Systems Validation Guideline, the advice of processing authorities should include reference to established scientific principles as well as reference to peerreviewed scientific data.", "67 Pathogens of Concern During Cooking Deviations Cooking deviations can allow pathogens that are controlled under normal cooking procedures to become a hazard, depending on the type of cooking deviation (described below) that occurs. Specific pathogens of concern may include: *Salmonella*, *STEC* (in beef products), and *Lm*, which could grow as vegetative cells to levels that overwhelm the Log reductions achieved by cooking. *S. aureus*, if allowed to grow to high levels, may produce heat-stable enterotoxins in the food. *Bacillus cereus* (*B. cereus*) (in rare cases), if allowed to grow to high levels in the food, may produce a heat-stable emetic toxin in the food or enterotoxins in the small intestine. *Clostridium perfringens* (*C. perfringens*) and *Clostridium botulinum* (*C. botulinum*) spore-forming pathogens that can germinate and grow in product held at higher temperatures (e.g., > 80°F). Again, it is important someone knowledgeable such as a processing authority evaluates each deviation to determine the pathogens of concern. Three Common Types of Cooking Deviations When cooking products to lethality, deviations may occur due to three main reasons: 1. The establishment fails to meet a time-temperature parameter in its lethality CCP for meat or poultry products. 2. The

establishment fails to maintain sufficient humidity during the cooking step. 3. Slow heating CUT allows product to remain at temperatures that allow pathogen growth (e.g., product remains at temperatures 50°F to 130°F for more than 6 hours; see FSIS Critical Operating Parameters for Cooking Come-Up-Time (CUT), page 23). Specific recommendations for evaluating each type of cooking deviation, including the pathogens of concern, are provided below. Alternatively, the establishment can provide additional support for the safety of the product (e.g., a journal article, or support from a processing authority). These are general recommendations; the specific responses will vary based on the unique factors of each deviation.

Type 1. Missed Endpoint Time-Temperature When evaluating product disposition after the process fails to meet an endpoint time or temperature parameter, the first step is to assess whether the process met a different time-temperature combination in the reference table. In some cases, the process may not have achieved an instantaneous lethality temperature (e.g., 158°F for meat) identified in the CCP but may have achieved the dwell time needed for a lower", "68 temperature in the same table (e.g., 154°F for 27 seconds) when considering the total time product temperature was at or above the lower temperature. Did the process meet a different validated time-temperature combination? \u2022 If yes, then product is safe to release. \u2022 If no, then FSIS recommends contacting a processing authority who may help you identify proper D and z values to calculate integrated process lethality considering the product come-up -time and come-down-time. One common tool for calculating integrated lethality is the AMI Process Lethality Determination Spreadsheet. If properly conducted, the AMI lethality spreadsheet is a sound scientific approach for determining the overall lethality of a cooking process (Scott and Wedding, 1998). The D-values at the reference temperature for the three main pathogens of concern (*Salmonella* spp. *E. coli* O157:H7, and *Lm*) are generally conservative values and should be valid for most cooked meat ready-to-eat (RTE) processes provided that the product is moist when cooked (high relative humidity). However, if the product is not moist when cooked and the product surface is allowed to dry out during the lethality step, the D-values referenced in the AMI lethality spreadsheet are not valid. NOTE: There are many complexities involved in identifying appropriate D and z values needed as inputs for calculating integrated pathogen lethality. FSIS advises establishments to work with a processing authority or someone knowledgeable in thermal death-time values, to ensure they select appropriate values and are properly using the lethality calculator. \u2022 Establishments may consider re-cooking the product, but only if all critical operating parameters (including relative humidity and CUT time) were met during the initial heating and during re-cook. o If the relative humidity option in the scientific support was not applied, the establishment should also follow recommendations for evaluating a Type 2 Deviation: Insufficient Humidity During Cooking described on page 69, or o If the CUT parameter was not met, the establishment should also follow recommendations for evaluating a Type 3 Deviation: Long Heating CUT described on page 70, and contact a processing authority for assistance. NOTE: Cooking deviations that combine a missed time-temperature parameter with a long CUT are complex situations which may require considering *C. perfringens* and *C. botulinum* as described in the Stabilization Guideline, in addition to the other pathogens of concern.", "69 \u2022 If establishments cannot re-cook the product, they should consider the following alternative actions: o Provide alternative support (page 55) (e.g., information from a processing authority that includes scientific citations that product is safe to release); o Sample

and test the product (see Product Testing recommendations for Type 1 deviations, page 77); or

- o Destroy the product (renderer or landfill).

Type 2. Insufficient Humidity During Cooking As described on page 16, some bacteria can become more heat tolerant when they are exposed to moderate levels of heat, drying, and other factors. Bacteria can then survive at higher temperatures than they normally would. Below are general recommendations for an establishment to consider when evaluating products after a Type 2 cooking deviation resulting from insufficient humidity (i.e., the relative humidity option in the scientific support was not followed) during cooking.

- \u2022 Consider sampling and testing product for *Salmonella*, Lm, and *E. coli* O157:H7 (if a beef product), using a statistically based sampling program as described in Product Testing on page 77.
- \u2022 If recocking, apply a higher time-temperature combination validated to achieve lethality in a product with similar intrinsic factors (e.g., water activity).
- o It would not be appropriate to recock the product following FSIS Relative Humidity Options (page 26) without additional support that recocking conditions adequately rehydrate the product surface (see Attachment A6. Cooking Country-Cured Hams, page 90).
- o Under these circumstances, FSIS would need to verify that such scientific support is adequate in the context of the specific product, process, and situation. Examples of acceptable support may include support that:

- \u2022 Demonstrates that a validated wet bulb temperature target has been met to ensure lethality. To show that the surface has been rehydrated, the wet bulb target should be higher than the product surface temperature.
- \u2022 Includes water activity testing: A water activity increase after recocking (compared to water activity before recocking), may indicate that the surface has been rehydrated.

"70 NOTE: FSIS is not aware of any research validating recocking procedures for products that may have heat tolerant *Salmonella* because of a lack of relative humidity during the initial cook. However, FSIS plans to update these recommendations as more research becomes available.

Type 3. Long Heating CUT If the total time between 50 and 130\u00b0F is longer than hours 6, recocking alone may not be sufficient to ensure the safety of the product. That is because during the extended CUT toxigenic pathogens could grow rapidly (e.g., *S. aureus*), allowing enterotoxins to form. Some enterotoxins are extremely heat-stable and are not inactivated by normal cooking temperatures. Therefore, it is not always possible to recock the product alone to ensure its safety. The establishment should continue to recock the product to address vegetative pathogens (e.g., STEC, Lm, and *Salmonella*). It should also provide additional support that heat-stable enterotoxins do not present a hazard in the product after the recocking step. As noted in Type 1. Missed Endpoint Time-Temperature, cooking deviations that combine a missed time-temperature parameter with a long CUT are complex situations that may require considering *C. perfringens* and *C. botulinum* as described in the Stabilization Guideline, in addition to the other pathogens of concern. The establishment may want to contact a processing authority for assistance. To determine product disposition after a long heating CUT deviation, the establishment should:

1. Address growth of vegetative pathogens that do not produce toxins, AND
2. Address the potential enterotoxin formation as described below. If either hazard is not controlled to safe levels, then product should be destroyed. Further guidance on these two recommendations is provided below:

- 1. Address growth of vegetative pathogens: (e.g., STEC, Lm, and *Salmonella*).
- o FSIS recommends that establishments use microbial modeling (page 72) and other information (e.g., scientific journal articles, book chapters, and processing authorities) to estimate growth of *E. coli*, Lm, and *Salmonella*.

\u2022 If modeling estimates the growth of vegetative pathogens to be 1Log or less,

provided the predictive microbial modeling program is validated, modeling is adequate to show that the process prevented vegetative pathogen outgrowth and the establishment can address the potential for enterotoxin formation (see 2 on the next page). \uf0a7 If modeling estimates more than 1-Log growth of any vegetative pathogen, establishments should recook product OR sample and","71 test for vegetative pathogens to determine the safety of the product (see Type 3 deviation recommendations in Product Testing, page 77). \u2022 Many establishments avoid the cost of sampling and testing by recooking the product or consulting a processing authority to identify alternative support that vegetative pathogens are addressed. \u2022 If product is recooked, it should be done to a higher time and temperature that has been shown to achieve enough additional Log reductions to address the amount of vegetative cell growth the model predicted. Using a recock procedure that achieves the correct additional Log reduction is important to ensure increased pathogen load will not overwhelm the Log reductions achieved during the recock procedure (see page 72). For example, if predictive microbial modeling showed a 2.5-Log and 3.0-Log increase for Salmonella and E. coli O157:H7, respectively, in a roast beef product, the recock step should be adjusted so that the cooking time-temperature combination can achieve at least a 9.5-Log reduction of Salmonella instead of a 6.5-Log reduction. The AMI Process Lethality Determination Spreadsheet discussed on page 68 may be used to support the cooking time-temperature combination can achieve sufficient Log reductions.

2. Address potential enterotoxin formation: (e.g., S. aureus) by demonstrating that toxicogenic pathogens did not grow to levels of public health concern or produce enterotoxin. o FSIS recommends that establishments use microbial modeling (page 72) and other information (e.g., scientific journal articles, book chapters, and processing authorities) to provide additional information to determine product safety. \uf0a7 If predictive microbial modeling estimates a < 3-Log growth of S. aureus, modeling is adequate to show that the process prevented enterotoxin formation provided the predictive microbial modeling program is validated. If growth of vegetative pathogens is also addressed the product can be released. NOTE: Due to the rapid growth of S. aureus in meat and poultry products, modeling for B. cereus (which grows slower) is not needed when S. aureus growth is controlled (< 3-Log). \uf0a7 If microbial modeling estimates a \u2265 3-Log growth of S. aureus, then product should be tested for S. aureus enterotoxins A, B, C,","72 D, and E using a statistically representative sampling procedure. If the product contains non-meat ingredients previously associated with B. cereus associated illnesses (e.g., rice, or pasta) and microbial modeling estimates > 3-Log growth of S. aureus, then establishments may also want to consider testing for B. cereus emetic toxin (Product Testing page 77). NOTE: As stated previously, conditions that allow for 3-Log or higher growth of S. aureus are a public health concern (ICMSF, 1996). Furthermore, this level of growth (i.e., 3-Log) for S. aureus is consistent with the pass\fail criteria developed by the Institute of Food Technologists (IFT) for the FDA to control for this food safety hazard (IFT, 2003). Predictive Microbial Modeling Establishments may use predictive microbial modeling to estimate the relative growth of bacteria during a long heating CUT deviation (Type 3). As explained above for Type 3 heating deviations, modeling results can be used to support various product disposition options including release, recocking, sampling and testing, or destruction provided the model used has been validated. Predictive microbial modeling tools may be used to evaluate product disposition in the event of other types of deviations (e.g., for Type 1 deviations establishments may use the AMI Process Lethality Determination Spreadsheet).

However, this section is focused on evaluating product disposition during Type 3 heating deviations due to their complexity. When performing predictive microbial modeling, it is important that establishments:

1. Use validated models (see examples below):
  - o It is not appropriate to rely solely on one model unless the model has been validated for the particular food of interest. A validated cooking model is a model whose predictions have been found to agree with or are more conservative than actual observed results. If a model has not been validated for a particular food of interest, the establishment should provide additional supporting documentation to support the results from the model (e.g., sampling data or comparison with other model results).
  2. Enter accurate product formulation information: To support safe release of the product, both the vegetative pathogens and enterotoxin formation must be addressed with supporting documentation. If either hazard is not controlled to safe levels, then product should be destroyed."
  3. Enter accurate time and temperature information in the model:
    - o When entering time and temperatures into the model, the establishment should include all parts of the process, including cooking and recooking CUTs after a Type 1 or 3 cooking deviation. If the establishment does not include all parts of the process, it may underestimate pathogen growth.
    - o When determining the temperature, the establishment should take into account both the temperature at the coldest internal area (center) of the product and at the surface of the product.
    - o It is important to obtain an internal time and temperature profile of the product, and a wet bulb time and temperature profile of product since wet bulb can be used to describe the product\u2019s surface temperature. If an establishment does not have wet bulb temperature data, it can conduct predictive microbial modeling using the internal time-temperature profile of the product, provided that sufficient humidity was used during cooking. However, the establishment should take into account that the product surface temperature will be higher than the center of the product under high relative humidity conditions.
    - o For cases with large time gaps between known temperature observations, establishments may consider interpolating to estimate additional timetemperature data points between known observations assuming linear heating. However, if the product temperature dwells or holds between 90 and 120\u00b0F (the optimal growth range of *S. aureus*) for an extended period of time, excess *S. aureus* growth could result in a potential hazard in the product being uncontrolled. The establishment should consider the likely accuracy of the predicted growth when making a product disposition determination using linear interpolation.
    - o Assume no *S. aureus* growth above 120\u00b0F. NOTE: FSIS has included the time that product remains from 120 to 130\u00b0F in the heating CUT option (page 23) to reduce the risk *B. cereus* (a spore-former) could germinate and then grow at these higher temperatures, potentially producing a heat-stable emetic toxin."
4. Address model limitations in a conservative manner:
  - o If product characteristics or other conditions are outside the range of the model, accuracy is not guaranteed. Establishments should support how the model results represent the product or the worst-case scenario for the hazard in the product or should compare the results to several other pathogen models and should make decisions based off the model that shows the worst-case scenario (i.e., for *S. aureus* that is the model that

estimates the most outgrowth). NOTE: This guidance contains recommendations for addressing certain limitations in two recommended models at the time the guidance was written. Neither modeling program is controlled by USDA-FSIS and may change. FSIS will update its modeling recommendations in future revisions to be consistent with any changes made to the modeling programs. Recommended Models \u2022 Therm 2.0 model (*S. aureus*, *Salmonella*, and *E. coli* O157:H7). The University of Wisconsin Therm 2.0 model is designed to allow processors to input the product\u2019s time-temperature profile and it has been validated for estimating the growth of *S. aureus*, *Salmonella*, and *E. coli* O157:H7. The three input variables and their ranges for entering into the growth model are provided below (Ingham et al., 2009): o Input variables and ranges: \uf0a7 Temperature profile: 50\u00b0F to 110\u00b0F (10\u00baC to 43.33\u00baC) \uf0a7 Date\time: the model allows for entry of calendar date and time \uf0a7 Meats: \u2022 In meat and poultry products containing salt (\u2264 2.5%), establishments should use the Therm 2.0 model for Bratwurst for predicting pathogen growth. This model should be used because it was designed to take into account the bacterial pathogen\u2019s behavior in pork sausage and related products that contain higher fat levels, sodium chloride, and spices. For example, adding salt to product will inhibit the competing microorganisms, but allow for greater growth of salt tolerant *S. aureus*; the Therm 2.0 model will predict this. Because the Therm 2.0 model for Bratwurst was developed with data from a pork product, establishments should compare the results with another model, such as the DMRI Staphox Predictor when evaluating deviations involving poultry products.", "75 \u2022 In meat and poultry products without any added salt, establishments should use the Therm 2.0 model for Beef, Pork, or Poultry based on the product type (Ingham et al., 2009). o Overcoming model temperature limitations: (maximum 110\u00b0F) \uf0a7 The Therm 2.0 model does not automatically interpolate (estimate a linear change) between time-temperature data points entered by the user. Therefore, FSIS recommends establishments enter temperature observations for at least every 30 minutes, or at the lowest time interval available. \uf0a7 For temperatures >110\u00b0F, substitute 110\u00b0F for any temperature above 110\u00b0F up to 120\u00b0F. *S. aureus* grows fastest at 110\u00b0F. The growth rate slows as temperatures increase from 110 to 120\u00b0F. Modeling using 110\u00b0F for temperatures observed from 110 to 120\u00b0F will slightly overestimate the growth of *S. aureus*. \uf0a7 For temperatures between 120 and 130\u00b0F assume no growth of *S. aureus* (leave this out of the model). \u2022 DMRI Staphox Predictor (Version 1.0) (*S. aureus*) The Danish Meat Research Institute\u2019s (DMRI) Staphox predictor (Version 1.0) may also be used to predict the growth of *S. aureus* in meat and poultry products, with added salt (i.e., 1.8% to 4.2%). This model has been validated and was specifically designed to predict the growth of *S. aureus* in different meat product processes based on product composition and changes in temperature. The six input variables and their ranges for entering product composition information into the growth model are provided below (Gunvig et al., 2018): o Input variables and ranges: \uf0a7 Temperature profile: 32\u00b0F to 105.6\u00b0F (0\u00baC to 40.9\u00baC) \uf0a7 pH: 4.4 \u2013 6.1 \uf0a7 % sodium chloride (NaCl) in product (based on the total weight of the product formulation): 1.8 \u2013 4.2%. NOTE: The model converts % sodium chloride (NaCl) into the % water-phase salt. \uf0a7 % potassium chloride (KCl) in product (based on the total weight of the product formulation): 0.0 \u2013 4.2% \uf0a7 Sodium nitrite added to product: 0 \u2013 150 ppm \uf0a7 % water in final product (as determined through laboratory analysis):

62 \u2013 78%","76 o Worst Case Scenario: FSIS recommends using the values listed below as model inputs for any products where the values are unknown. These values represent a worst-case scenario for the growth of *S. aureus* based on product composition: \uf0a7 pH: 6.1 \uf0a7 % NaCl in product: 1.8% \uf0a7 % KCl in product: 0.0 \uf0a7 Sodium nitrite added to product: 0 ppm \uf0a7 % water in final product: 78% (highest allowed in model) \uf0a7 Initial level S. *aureus*: 100 CFU/g o Overcoming model temperature limitations: (maximum 105.6\00b0F) \uf0a7 For temperatures > 105.6\00b0F (40.9\00b0C), substitute 105.6\00b0F for any temperature above 105.6\00b0F (40.9\00b0C), up to 120\00b0F (48.9\00b0C). The fastest growth in this model is at 105.6\00b0F. As described above, *S. aureus* continues growing at higher temperatures, but the growth rate slows as temperature increases up to 120\00b0F (48.9\00b0C). For modeling, use 105.6\00b0F for temperatures observed from 105.8\00b0F (41\00b0C) up to 120\00b0F (48.9\00b0C), which will slightly overestimate the growth of *S. aureus* (fail-safe). \uf0a7 For temperatures between 120\00b0F (48.9\00b0C) and 130\00b0F (54.4\00b0C) assume no growth of *S. aureus* (leave out of the model). NOTE: Establishments may use the ComBase *S. aureus* model as support. However, this model has not been validated and establishments should follow the recommendation for using models that are not validated (i.e., compare the results of several models and make decisions using the worst-case results) as described above.","77 Product Testing As described in the cooking deviation and the microbial modeling recommendations (pages 67-72), if the establishment is unable to support the product disposition through predictive microbial modeling or some other means, the establishment can test a statistically-based number of samples of the product to support its safety. Table 7 identifies the hazards to be tested for according to the type of cooking deviation that took place. These are general recommendations; it is important that someone knowledgeable such as a processing authority evaluate each deviation to determine the appropriate sampling and testing plan. Table 7. FSIS Recommendations for Product Sampling and Testing After Each Type of Cooking Deviation to Determine Product Disposition

Type of Heating Deviation*	Vegetative Pathogens	Heat-stable Enterotoxins	Salmonella	Lm E. coli O157:H7	** <i>S. aureus</i> Enterotoxins A, B, C, D, and E
1 - Missed Time-Temperature	X X X	2 - Insufficient Humidity	X X X	3 - Long CUT	X Multiple Types in Combination (i.e., missed time-temperature AND long CUT)

Contact a processing authority for assistance evaluating product disposition in a complex deviation which combined multiple types of heating deviation. May need to consider *C. perfringens* and *C. botulinum* in addition to the hazards listed in this table.

\*Cooking deviation Types 1-3 are described on page 66. \*\*E. coli O157:H7 testing recommended only for products containing beef. Establishments may also choose to test for other STEC; however, testing for E. coli O157:H7 alone is sufficient. Sampling in Response to a Cooking Deviation \u2022 The establishment should test a statistically representative number of samples per lot depending on the bacterial pathogen. FSIS recommends testing at least 10-15 products per lot as outlined by the two-class sampling plan (Case 11 and Case 13, respectively) per the International Commission on Microbiological Specifications for Foods (ICMSF, 2002). \u2022 If the product contains non-meat ingredients previously associated with *B. cereus* associated illnesses (e.g., rice, or pasta) and microbial modeling estimates >3Log growth of *S. aureus*, then establishments may also want to consider testing for *B. cereus* emetic toxin.","78 NOTE: FSIS does not recommend all products to be tested for *B. cereus* emetic toxin due to the low incidence of *B. cereus* in raw meat and poultry. If you are uncertain if the

formulation of product affected by a cooking deviation may need to address *B. cereus* emetic toxin as a potential hazard, please contact askFSIS (page 9). Key Question Question: Can samples be composited for lab testing? Answer: It depends on what the sample is being tested for: \u2022 Enterotoxins? No. FSIS does not recommend compositing samples to be tested for enterotoxins. Combining multiple samples for a single test (i.e., compositing) could prevent the test from detecting enterotoxins in the product. \u2022 Vegetative pathogens? Yes. However, the number of samples that can be combined depends on the pathogen. Additionally, establishments should ensure the lab method has been validated for the larger test portion. o *Salmonella* and *E. coli* O157:H7: FSIS recommends compositing up to 3 samples (total 75g) for a total of 5 analyses although establishments may also be able to support compositing up to 15 \u2013 25-g samples (total 375 grams). The establishment would collect 15 samples from different pieces of product. The lab would combine the 25g sample from each of 3 different pieces, to make a 75g composited sample for analysis. The lab analyzes 5 composited samples. When compositing, establishments should ensure the method has been validated for the larger test portion. FSIS has validated a 325g test portion size for its analysis of RTE product samples collected under the RTEPROD program (see the FSIS\u2019 Microbiology Laboratory Guideline *Salmonella* Chapter). o Lm: FSIS recommends compositing up to 5 samples (total 125g) and 3 lab tests total. The establishment would collect 15 samples from different pieces of product. The lab would combine the 25g test sample from each of 5 different pieces, to make a 125g composited sample for analysis. The lab analyzes 3 composited samples. When compositing, establishments should ensure the method has been validated for the larger test portion. FSIS has validated a 25g and 125g test portion size for its analysis of RTE product samples collected under the RTEPROD and RLm programs, respectively (see the FSIS\u2019 Microbiology Laboratory Guideline *Listeria monocytogenes* Chapter).", "79 Disposition after Testing Results: To support the safe release of the product, every hazard associated with the type of heating deviation identified (see Table 7) must be controlled for the safe release of product. If any single hazard is not controlled, then product should be destroyed (renderer or landfill). \u2022 Enterotoxins: o If the product tests negative for enterotoxins, product can be released, unless insanitary (or other) conditions exist that could adulterate the product (e.g., vegetative pathogens). o If any enterotoxin is found, the lot is adulterated, and product should be destroyed (renderer or landfill).) \u2022 Vegetative Pathogens: o If the product tests negative for vegetative pathogens, product can be released, unless insanitary (or other) conditions exist that could adulterate the product (e.g., enterotoxins). NOTE: It would be inappropriate to test for live *S. aureus* instead of enterotoxin because it is possible for *S. aureus* to produce enterotoxins prior to the death of the bacteria (e.g., during cooking). The food product would still cause illness even though no vegetative bacteria were found. o If any vegetative pathogens are found, the lot is adulterated. Product may be: \uf0a7 Recooked per Type 1 or Type 2 recommendations (pages 67-69); or \uf0a7 Destroyed (rendered or denatured per 9 CFR 314.3(a), 9 CFR 325.11(a), 9 CFR 325.13(a)(1) through 325.13(a)(7), or 9 CFR 381.95 and sent to a landfill).", "80 Common Mistakes made by Establishments when Evaluating Heating Deviations\u2014and the Recommended Solutions 1) The establishment did not input an accurate internal time-temperature profile into the model. The establishment should be using a data logger or collecting time and temperature data at regular intervals during cooking. The establishment should take into account all parts of the process and temperatures at both the

center and surface of the product (Monitoring Endpoint Temperature page 21 and Monitoring Surface Temperature page 24). 2) In Type 1 or 3 deviations with a missed time-temperature parameter, the establishment failed to take into consideration the amount of bacterial growth that could occur during the cooking come-up-time when the cooking cycle was restarted. To address this issue, the establishment should consider both the original come-up-time, the initial cooling, and second come-up-time when the cooking is restarted as part of its modeling. 3) The establishment did not address whether additional growth of *Salmonella*, *E. coli* O157:H7 and Lm could have occurred during the Type 1 heating deviation and whether heat tolerance could have developed. To address this issue, when re-cooking the product, the establishment should increase endpoint temperature and apply sufficient humidity (FSIS Relative Humidity Options page 26). 4) The establishment failed to address the amount of growth of *S. aureus* and other bacterial pathogens that could occur on the product's surface. Measuring the temperature both at the product center and at the surface (wet bulb) temperature would address this issue. 5) The establishment failed to take into account the initial levels of *S. aureus* commonly found in raw meat and poultry. Levels of pathogens in raw product are approximately 2-Log. Increases of 3-Log or more could result in conditions where enterotoxin could be formed. Establishments should limit *S. aureus* growth to 2Log or less, to support safe release of product based on microbial modeling. See Biological Hazards of Concern During Cooking subsection: *Staphylococcus aureus* (page 14) for more information.", "81 Attachment A3. When can Products be Labeled as Pasteurized? FSIS defines pasteurization as any process, treatment, or combination thereof, that eliminates or reduces the number of pathogenic microorganisms to achieve at least a 5Log reduction of either *Salmonella* or Lm, on or in ready-to-eat (RTE) meat or poultry products in the final finished package. With adequate validation, pasteurization processes may include alternative technologies other than traditional cooking (e.g., high pressure processing (HPP)). FSIS considers products with a raw appearance that have been treated with a lethality process that renders the product RTE, and that are not post-lethality exposed (e.g., \u201csteak tartare\u201d subjected to a HPP treatment) as pasteurized. For the product to be labeled \u201cpasteurized,\u201d the treatment needs to: 1) Be applied in the final package (product is not post-lethality exposed); 2) Be sufficient to eliminate the number of pathogenic microorganisms to make the product safe for human consumption (so there are no detectable pathogens; RTE), and 3) Be effective for at least as long as the product shelf life. Establishments may label products as \u201cpasteurized.\u201d However, the term \u201cpasteurized\u201d is a special statement and claim that needs to be submitted to the Agency for label approval under 9 CFR 412.1(c)(3). The request for label approval needs to include supporting documentation providing evidence that the process achieves a 5-Log reduction of *Salmonella* or Lm. For more information see the FSIS Compliance Guidance for Label Approval. Irradiation is not a pasteurization process. Although the effect is similar to pasteurization, FSIS considers ionizing radiation a food additive under 9 CFR 424.22.", "82 Attachment A4. Sources of *Salmonella* Contamination in RTE Products and Best Practices to Address It Although the *Salmonella* percent positive found in ready-to-eat (RTE) products is low, the presence of *Salmonella* in RTE products may indicate a serious processing and public health problem. Common sources of *Salmonella* in RTE products include: \u2022 Under processing. \u2022 Cross-contamination. o Product contact surfaces that are contaminated with *Salmonella*; or, o Raw product contact with RTE product. \u2022 Ingredients

added to the product or the sauce after the cooking step. \u2022 Improper handling by establishment employees. \u2022 Insect or animal vectors. Each common source of Salmonella contamination on RTE products and best practices to prevent the hazard are discussed in detail below. Under-Processing Under-processing occurs when the lethality treatment is not adequate to eliminate the pathogens of concern. For heat-treated product, under-processing may result from inadequate cooking or the development of bacterial heat tolerance due to drying of the product\u2019s surface before completion of the lethality step because of inadequate humidity (see FSIS Critical Operating Parameters for Cooking (Time-Temperature Tables) page 23). Cross-Contamination Cross-contamination of product can occur from situations such as the following:

- \u2022 Using the same equipment (e.g., slicers) for both raw and cooked products without complete cleaning and sanitizing of the equipment (as should be addressed in the establishment\u2019s Sanitation Standard Operating Procedure (SOP)) after raw production and prior to RTE production.
  - o In a for-cause Food Safety Assessment (FSA) in response to a Salmonella positive in a RTE head cheese product, FSIS identified equipment used to grind both raw and cooked ingredients for head cheese was not cleaned and sanitized between use for raw and cooked meat potentially resulting in Salmonella cross-contamination.
- \u2022 Placing cooked product on the same surface (e.g., cutting table) as raw product without complete cleaning and sanitizing of the surface before reuse.", "83
- \u2022 Using the same utensils or containers (e.g., scoops or buckets) for both raw and cooked product.
  - o In two FSAs, popped pork skins were most likely contaminated with Salmonella when the same buckets and tongs were used for handling both raw and RTE product.

\u2022 Condensation or aerosolization in the processing environment. Best Practices to Prevent Cross-Contamination Under the HACCP regulations, establishments are required to prevent contamination of product with pathogens after the lethality step. Establishments are required to maintain sanitation in the RTE area to ensure that food contact surfaces are free of contamination from pathogens such as Lm and Salmonella. Best practices include:

- \u2022 Completely separating the processing areas by time or space (e.g., scheduling raw and RTE processing on different days).
- \u2022 Installing separate air ventilation systems that are designed to prevent or minimize condensation and other potential air contaminants. If separate ventilation systems are not feasible, ensure that airflow is directed from the RTE areas to the raw areas.
- \u2022 Using separate equipment for RTE and raw processing. If this is not possible, schedule use of equipment first for RTE processing and then for raw processing.
- \u2022 Restricting travel of personnel from the non-RTE area to the RTE area during processing.
- \u2022 Establishing proper sanitation procedures for equipment that is moved from a non-processing area to an RTE processing area to prevent product contamination from the equipment during operation.
- \u2022 Avoiding passing raw product through RTE areas and passing RTE product through raw production areas.
- \u2022 Not allowing RTE product in coolers to come into contact with raw products or surfaces that may be contaminated.
- \u2022 Discarding products that touch environmental surfaces (e.g., product that has fallen on the floor) if the product cannot be properly reconditioned to ensure that any possible contamination is eliminated.
- \u2022 During cleaning and sanitizing, following proper sanitation procedures to ensure that no food residue is left on the equipment."

"84

\u2022 When adding ingredients to a second container, avoiding any contact between the ingredient container and the interior of the second container. Ingredients Added After the Lethality Treatment Salmonella contamination may occur from the addition of uncooked vegetables

(e.g., tomatoes and onions), fresh herbs, eggs, spices (that may or may not have been treated to eliminate Salmonella), or other ingredients (e.g., nuts, hydrolyzed vegetable protein (HVP)) to processed meat and poultry products after the primary lethality treatment. Sauce that has not undergone a lethality treatment may also be a source of contamination of the finished product, even if the pH is low. The safety of all ingredients added to the product after the lethality step should be considered, even if they are normally considered RTE. In some cases, FSAs determined the addition of seasonings or other ingredients after the cooking step resulted in the contamination of RTE product with Salmonella. Failure to identify all steps in a process, including the addition of contaminated ingredients and sauces, can result in an inadequate food safety system. Outbreaks related to ingredients added after lethality treatment An outbreak and several recalls of meat and poultry products that were prepared using Salmonella-contaminated ingredients exemplify the need to ensure the safety of all ingredients added to the product after the lethality treatment. Examples include a 2010 outbreak-related recall of salami products coated with contaminated pepper (RC-0062010) and recalls involving products containing HVP that was the subject of an FDA recall (i.e., bacon base, RC-015-2010; beef tornados, RC-016-2010, and beef taquitos and chicken quesadillas, RC-017-2010). RC-055-2010 may have been due to contaminated sauce added to the product after the lethality step. There have also been two recalls of meat and poultry salads containing Salmonella contaminated tomatoes recalled by the supplier (RC-033-2011 and RC-79-2011), and Caesar salad containing contaminated cilantro that was the subject of an FDA recall (RC-059-2012). In 2018, there were 12 recalls due to potential vegetable contamination with Salmonella and Lm that were triggered by an FDA investigation and subsequent recall from the same supplier (RC-092-2018, RC-093-2018, RC-094-2018, RC-095-2018, RC-096-2018, RC-097-2018, RC-098-2018, RC-099-2018, RC-100-2018, RC-1012018, RC-102-2018, and RC-103-2018).", "85 Requirements and Best Practices to Prevent Hazards from Ingredients Added Post-Lethality Establishments are required to:

- \u2022 Ensure all ingredients and other articles used in the preparation of any meat or poultry product are clean, sound, healthful, wholesome and otherwise such as will not result in the product being adulterated (9 CFR 318.6 and 9 CFR 424.21).
- \u2022 Consider any potential food safety hazards at the step in the process where the non-meat ingredient is received into the food safety system (9 CFR 417.2(a)(1)) and document any controls it needs to support its decisions (9 CFR 417.5(a)(1)) about those hazards.

o Establishments may choose to use COAs that include negative test results for each lot of the non-meat ingredient as support or may test each lot of non-meat ingredients upon receipt; however, establishments have flexibility and do not have to only rely on testing.

- o Alternatively, establishments may maintain supporting documentation demonstrating that the ingredients such as spices, have been treated by processes to kill pathogens (e.g., irradiation, ethylene dioxide, steam treatment of spices), or they can apply a lethality treatment to the ingredients (e.g., cook the sauce of a pork BBQ).
- o In most cases, a LOG alone would not be sufficient to support the safety of non-meat ingredients added to a product unless they indicate how each lot of ingredients is processed, tested, treated, or otherwise processed to ensure its safety as described in the bullet above.
- o A LOG can be used to support the safety of pre-packaged ingredients (e.g., ketchup or mustard) that have not been associated with previous outbreaks or recalls.

NOTE: Many frozen vegetables are considered NRTE by the producing facility. FSIS recommends establishments that do not receive a COA or LOG as described in the bullets

above, treat all frozen vegetables as NRTE and address potential hazards from this ingredient (e.g., by testing each lot of non-meat ingredients upon receipt or applying a validated lethality treatment). Additionally, any vegetables labeled with cooking instructions are to be treated as NRTE. \u2022 Developing procedures to ensure that spices or other source materials are maintained under sanitary conditions and are not contaminated by the introduction of pathogens during repeated opening of the container and removal of the ingredient for use in multiple production lots.", "86 \u2022 Taking steps to ensure sauce used for RTE products is also not contaminated by exposure to unclean surfaces, untreated ingredients, or contact with raw products. Food Handlers There is a high incidence of salmonellosis in the US. Additionally, some people can be asymptomatic carriers that spread Salmonella without appearing ill. Establishment employees that are asymptomatic carriers may be a source of Salmonella in RTE products. Best Practices to Prevent Hazards from Food Handlers Food handlers, employees, and supervisors at food preparation facilities should: \u2022 Stay home from work when having symptoms of vomiting or diarrhea and wait to resume work until at least 24 hours have passed since the vomiting and diarrhea symptoms ended. \u2022 Wash hands upon resuming duties after breaks and before putting on gloves. \u2022 Wear separate or color-coded frocks in RTE areas of the establishment and control employee traffic between raw and RTE production areas. \u2022 Train employees in proper hygiene practices, and regularly monitor those practices, and retrain employees at least annually. \u2022 Develop and maintain procedures to ensure that sanitizer concentrations in footbaths are monitored and maintained adequately. Animals Animals (e.g., birds and rodents) and insects may also contaminate food products with Salmonella. It is possible for animal fecal contamination within and outside the establishment to be introduced into the RTE production area. Best Practices to Prevent Hazards from Animals \u2022 Maintaining an effective pest control program to maintain sanitary conditions and ensure that product is not adulterated (9 CFR 416.2(a)). Rats, mice, birds, and insects are sources of pathogen contamination. \u2022 Product and ingredients should always be protected from contamination and adulteration during processing, handling, and storage (9 CFR 416.14)." "87 Attachment A5. RTE Salmonella Self-Assessment Tool FSIS recommends that establishments use this tool to determine whether they have adopted the appropriate procedures to control Salmonella, or whether they should adopt new procedures. If establishments find that they are not meeting the recommendations in this guideline, FSIS recommends they consider changing practices to better control Salmonella in the product. The questions are related to evaluating the following: \u2022 Hazard Analysis\HACCP Plan \u2022 Ingredients \u2022 Corrective Actions in Response to Salmonella Positives Hazard Analysis\HACCP Plan YES NO N/A 1. Have you considered whether Salmonella is a hazard reasonably likely to occur (RLTO) in your Hazard Analysis? \u25a1 \u25a1 \u25a1 2. If you determined that Salmonella was RLTO, did you establish CCPs to control or prevent it? \u25a1 \u25a1 \u25a1 3. If you established CCPs, do you have sufficient supporting documentation to support the effectiveness of the measures you are taking? \u25a1 \u25a1 \u25a1 4. If you produce roast, cooked, or corned beef, does your process achieve at least a 6.5-Log or other supportable (e.g., 5-Log) reduction of Salmonella? \u25a1 \u25a1 \u25a1 5. If you produce cooked uncured meat patties, does your process achieve at least a 5-Log reduction of Salmonella? \u25a1 \u25a1 \u25a1 6. If you produce cooked poultry, does your process achieve at least a 7-Log reduction of Salmonella? \u25a1 \u25a1 \u25a1 7. If you produce other cooked

RTE meat products, does your process achieve at least a 6.5-Log or other supportable (e.g., 5-Log) reduction of Salmonella in the product? \u25a1 \u25a1 \u25a1 8. If you are using an alternative lethality Log reduction target (e.g., 5-Log reduction) do you have additional support such as COA, LOG, combined interventions, or baseline testing? \u25a1 \u25a1 \u25a1 9. As part of your critical limits, have you identified the target or performance standard that your \u25a1 \u25a1 \u25a1,"88 process is designed to achieve (9 CFR 417.2(c)(3))? 10. If you produce cooked products and use a time- temperature table, are you applying humidity during the cooking process? \u25a1 \u25a1 \u25a1 11. If \u201cno\u201d to the question above, do you have support for why relative humidity is not a critical operating parameter? \u25a1 \u25a1 \u25a1 12. If \u201cno\u201d to the question above, are you applying a scientific gap for lack of relative humidity? Which one? (fill in here) \_\_\_\_\_ \u25a1 \u25a1 \u25a1 13. If you produce cooked products and use a FSIS time-temperature table, have you limited product heating come-up-time (50 to 130\u00b0F) to 6 hours or less? \u25a1 \u25a1 \u25a1 14. If \u201cno\u201d to the question above, do you have alternative support for applying a long come-up-time? \u25a1 \u25a1 \u25a1 15. If \u201cno\u201d to the question above, are you applying a scientific gap for long come-up-time? \u25a1 \u25a1 \u25a1 Ingredients YES NO N\A 16. Do you add ingredients to the product after the lethality treatment? (if \u201cno,\u201d move to the next section) \u25a1 \u25a1 \u25a1 17. Do you maintain COAs, LOGs, or other information (e.g., sampling data) to support the safety of the ingredients? \u25a1 \u25a1 \u25a1 18. If you use LOGs, do they indicate how each lot of ingredients is processed, tested, or otherwise treated to ensure its safety? \u25a1 \u25a1 \u25a1 19. Are the ingredients that you add to the product included in your flow chart or hazard analysis? \u25a1 \u25a1 \u25a1 20. If you use pre-packaged ingredients that are included in the final package with the finished product do you have LOGs or other information to support their safety? \u25a1 \u25a1 \u25a1,"89 Corrective Actions in Response to Salmonella Positives YES NO N\A 21. Has a RTE product sample tested positive for Salmonella from FSIS or establishment testing? (If \u201cno\u201d the assessment is complete). \u25a1 \u25a1 \u25a1 22. If you control Salmonella in your HACCP plan, did you take corrective actions according to 9 CFR 417.3(a)? (If you prevent Salmonella through a Sanitation SOP or other prerequisite program, skip to #26). \u25a1 \u25a1 \u25a1 23. Did you take steps to identify and eliminate the cause of the deviation, according to 9 CFR 417.3(a)(1)? \u25a1 \u25a1 \u25a1 24. If the cause of the positive result is under- processing, did you immediately review your processing system and bring the process back into compliance? \u25a1 \u25a1 \u25a1 25. If the cause of the positive result is lack of support for your lethality process, did you change your process or provide additional support for the safety of the process, in light of the positive result? \u25a1 \u25a1 \u25a1 26. If you prevent Salmonella through a Sanitation SOP or another prerequisite program, did you take corrective actions according to 9 CFR 417.3(b)? \u25a1 \u25a1 \u25a1 27. As part of your corrective actions, did you reassess your HACCP plan according to 9 CFR 417.3(b)(4)? \u25a1 \u25a1 \u25a1 28. As a result of your reassessment, did you address the pathogen in a CCP or make substantive changes to your prerequisite program? \u25a1 \u25a1 \u25a1,"90 Attachment A6. Cooking Country-Cured Hams In October 2018, an establishment recalled cooked country-cured ham product that was associated with a listeriosis outbreak (Recall 084-2018; CDC: Outbreak of Listeria Infections Linked to Deli Ham). FSIS\u2019s investigation at the establishment found that the country-cured hams were

cooked in a sealed bag multiple times. Before being cooked multiple times, the ham was salt-cured and dried, thus reducing its water activity. Additionally, after an initial cooking step in a sealed bag, the ham was removed, drained of its juices, and placed into a second bag; during this process, the ham may have been cross-contaminated from the processing environment. Additionally, the draining of juices may have resulted in drier conditions during cooking. The establishment used FSIS cooking guidance (Appendix A) as scientific support that cooking achieved lethality of pathogens, including Lm. However, as discussed on page 12, Appendix A guidance was not intended for lower water activity products cooked under dry conditions or for dried products cooked multiple times. Hence the process may not have been lethal to Lm (USDA/FSIS, 2020). Establishments that apply these types of processes must identify other support for their HACCP System (9 CFR 417.5(a)(1) and 9 CFR 417.4(a)(1)). During the outbreak investigation, FSIS also discovered that several establishments cook country-cured hams once under moist conditions using FSIS cooking guidance as support. FSIS cooking guidance was also not intended for lower water activity products cooked even under moist conditions; however, FSIS is not aware of any imminent food safety issues with this practice. Therefore, page 47 (Table 5), includes critical operating parameters that may be applied to cook dried products like country cured hams if they are cooked once under moist conditions to rehydrate the surface. While cooking under moist conditions should rehydrate the surface, there is no research validating this process so it is considered a scientific gap. As with other scientific gaps, there is a vulnerability because FSIS's lethality guidance is not designed for processes where the drying step comes before the moist cooking step. This is because cooking under low moisture conditions results in product with a lower water activity. These conditions lead to pathogens, such as Lm, becoming more heat-tolerant and the organism could survive the cooking process. To minimize this vulnerability, FSIS recommends: If the product is cooked once: Establishments should gather support such as water activity measurements after drying (before cooking), then again after cooking to demonstrate that the water activity increased, and product surface was rehydrated during cooking. This recommendation applies even if the product is cooked-in bag, because the water activity may not be high enough to ensure that pathogens are killed on the product without addition of moisture. Establishments should achieve the highest water activity possible during cooking. Values 0.96 have been shown to prevent bacterial heat tolerance", "91 (Kieboom, et al. 2006), but this water activity may not be possible for all processes to achieve. Establishments conduct finished product testing for Salmonella and Lm as part of on-going verification. Establishments should also ensure that the cooking bag is completely sealed, so that moisture is contained in the bag and the product is not exposed to the environment or contaminants. Cooking bags may be compromised during steps such as molding or shaping. The establishment should have a process to verify the package integrity, and if leaks are observed, the establishment should reprocess/recook the product, using a supported process.", "92 https://www.fsis.usda.gov/contact-us/askfsis FSIS/USDA www.fsis.usda.gov 2021"]}, {"file\_name": "FSIS\_GD\_2021\_0015", "title": "HACCP Model for Raw Intact Beef", "num": "FSIS-GD-2021-0015", "id": "80b3ddb50c6f044e66fac42d74ca38b17faf021000fe72ee12d73399d2f33f30", "corp\_us": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/media\_file/2021-"}]

12\FSIS-GD-2021-0015.pdf","type":"pdf","n\_pages":11,"word\_count":3352,"text\_by\_page":["Page 1 of 11 HACCP Model for Raw Intact Beef The United States Department of Agriculture (USDA) published the Pathogen Reduction\Hazard Analysis Critical Control Point (HACCP) Systems Final Rule in July 1996 mandating all USDA inspected meat and poultry establishments implement a HACCP system. Hazard Analysis Critical Control Point (HACCP) is a systematic and scientific method of process control for the production of safe food products. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to improve the safety of their products. The HACCP models\u2019 focus is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic model for each food processing category defined in the regulation (9 CFR 417.2(b)(1)). The guidebook and the generic models have been revised since their initial publication to be consistent with current science and policy. FSIS recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used as is. Establishments are to tailor the model(s) to fit the establishment\u2019s operation. The raw intact1 beef model\u2019s critical control points (CCPs) do not necessarily apply to all operations or products. Products or operations may require fewer or more CCPs depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The food safety critical limits selected must come from scientific documents or other reliable sources. Each model includes references for guidance on the selection of critical limits. This model illustrates how establishments might include beef intended for intact use in the production of steaks and roasts. The sources of beef in this model are purchased product intended for intact use and product from in-house slaughter operations. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis, are HACCP records (CFR 417.5(a)). The selection of processing categories and HACCP models are preliminary steps to completing a hazard analysis. The documents produced during the selection process are HACCP records. Ensure you maintain the documents produced while developing a HACCP plan. For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage.<sup>2</sup> 1 FSIS considers raw products to be intact unless they have undergone any of the processes associated with the raw non-intact process category. Processes common to the non-intact category include grinding, comminuting, injecting product with solutions, or mechanical tenderization by needling, cubing, pounding devices or other means of creating non-intact product. 2 This information is best suited for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP model is for demonstration purposes only. The model does not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products."],"Page 2 of 11 EXAMPLE PRODUCT DESCRIPTION3 Process Type and Product Name: Raw Intact Beef Process

Type and Product Name Raw Intact Beef: steaks and roasts. Important product characteristics (Aw, pH, preservatives, etc.) None How it is to be used4 The products are to be cooked intact while using the validated cooking instructions.5 Packaging (durability and storage conditions) Tray packages, vacuum sealed packages or in butcher paper. Shelf Life and at what temperature6 Shelf life is 7 days when held at \u226440\u00b0F and paper wrapped; 60 days when held at \u226440\u00b0F and vacuum packed.7 Vacuum packed product can be held for 180 days at \u226410\u00b0F. Where it will be sold (specify intended consumers, especially at-risk populations8) Sold to household consumers through retail outlets or distributed to hotels, restaurants, and institutions (HRI). Labeling Instructions Product name, inspection legend and establishment number, handling statement, net weight statement, address line, nutrition facts, and safe handling instructions. Validated cooking instructions.9 What special distribution controls are required? None DATE: APPROVED BY: 3 Prior to developing the HACCP plan please read the FSIS Guidebook for the Preparation of HACCP Plans for detailed descriptions of the worksheets and hazard analysis. The FSIS Guidebook for the Preparation of HACCP Plans and the generic HACCP models are intended for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP models are for demonstration purposes only. The models do not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. 4 The intended use or consumer of the product must be identified in accordance with 9 CFR 417.2(a)(2). Identifying the product\u2019s intended use in the product description is one way to meet the regulatory requirements specific to 417.2(a)(2). 5 Establishments are required to identify the intended use of the product (9 CFR 417.2(a)(2)); they are also required to maintain decisionmaking documents associated with the HACCP plan (9 CFR 417.5(a)(2)). See the Adequate Support for the Intended Use of Beef Primal and Subprimal Cuts FSIS knowledge article for additional information. 6 Each establishment\u2019s products may have their own defined shelf life. 7 See Beef Shelf-life. 8 At-risk populations include young children, the elderly and immunocompromised persons. 9 See the FSIS Labeling Overview and Generic Label Approval guideline for information on required labeling features.", "Page 3 of 11 EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING MATERIAL10 Process Type and Product Name: Raw Intact Beef Meat and Meat by-products In-house slaughtered beef primals and sub-primals intended for intact use. Purchased beef sub-primals intended for intact use. Non-meat food ingredients None Antimicrobial11 Interventions and processing aids None Packaging Material Plastic, foam, or paper. Finished Product Cold Storage 7. Trimmings from Fabrication and Cutting", "Page 5 of 11 15 STEC is an adulterant in raw non-intact beef products. When STEC is present on the meat\u2019s exterior, the pathogen may be translocated to the interior of the product during processing (e.g., grinding, tenderizing). In such cases, normal cooking to a rare or medium-rare internal state may not be sufficient to destroy STEC that is present throughout the product. See the Industry Guideline for Minimizing the Risk of Shiga Toxin-Producing Escherichia coli(STEC) in Raw Beef (including Veal) Processing Operations (page 8) for additional information. EXAMPLE HAZARD ANALYSIS Process Type and Product Name: Raw Intact Beef Column 1 Column 2 Column 3 Column 4 Column 5 Column 6

Ingredient \ Process Step Potential Hazards (introduced or controlled) at this Step i Is the Potential Food Safety Hazard Reasonably Likely to Occur (RLTO)? (Yes or No) ii Justification \ Basis for Decision iii If yes in Column 3 (hazard RLTO), What Control Measures Can Be Applied to Prevent, Eliminate, or Reduce the Hazard to Acceptable Levels iv Is this Step a Critical Control Point (CCP)? 1a. Meat Receiving: beef from inhouse slaughter intended for intact use B:

Presence of pathogens: Shiga-toxin producing Escherichia coli (STEC) (E. coli O157:H7, O26, O45, O103, O111, O121 and O145), and Salmonella B: Outgrowth of pathogens: STEC and Salmonella. No No STEC and Salmonella are known to be present and may cause illness if not controlled. In-house product from slaughter operations was subjected to slaughter sanitary dressing procedures, a Zero Tolerance CCP, and an Organic Acid CCP. STEC is not an adulterant on intact products intended for intact use as the contamination is limited to the exterior of the product whereby customary consumer cooking practices will destroy the pathogen on the exterior surface even if the interior of the product is consumed in a rare or medium rare state. 15 Temperature Control Standard Operating Procedure (SOP) for maintenance of cold storage room temperature.", "Step Potential Hazard RLTO Justification \ Basis Controls CCP

Page 6 of 11 16 The Significance of time-temperature to growth of foodborne pathogens during refrigeration at 40-50\u00b0F (Tompkin, R.B. 1996) 17 If an establishment implements a process consistent with the process specifications described in the scientific support, and the

scientific support contains microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, the in-plant validation data collected during the 90 day initial validation period will consist of data on quantifiable characteristics of the critical operational parameters, such as pressure, temperature, and concentration. However, if an establishment implements different critical operational parameters in the process from the scientific support, or the scientific support identified does not contain microbiological data, then the establishment should collect in-plant data demonstrating the critical operational parameters that it has implemented can all be met AND should collect in-plant microbiological validation data or identify scientific support with microbiological data that demonstrates the effectiveness of those implemented critical operational parameters (FSIS Compliance Guideline HACCP Systems Validation, page 27).<sup>18</sup> A LOG is a document that provides details for components that are used in the areas of food processing, handling, and storage. Generally, a LOG contains: supplier name and address, brand name, statement that the material is safe and effective under intended conditions of use and will not adulterate the food product, and signature of an official of the supplier. The LOG may be attached to an invoice or may be a continuing LOG that does not accompany each shipment. An annual update for Letters of Guarantee (LOG) is not a regulatory requirement. Each establishment must determine the frequency at which the LOG are updated. The frequency should be sufficient to adequately describe the supplier's process to support the decision(s) made. B: Bovine Spongiform Encephalopathy (BSE) Prions associated with Specified Risk Materials (SRM) (9 CFR 310.22). No Written Cold Storage Program to receive product \u226444.6\u00b0F to prevent outgrowth (Tompkin, R.B. 1996).<sup>16,17</sup> Written SRM Program to remove, segregate and dispose of SRMs (9 CFR 310.22). ","Page 11 of 11 i Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P). Biological hazards are living organisms. Chemical hazards may be naturally occurring in foods, used or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification. ii Place the justification for your decision in column 4. Control measures for hazards not reasonably likely to occur are entered in column 4. Control measures for hazards reasonably likely to occur are entered in column 5. If a hazard is reasonable likely to occur, then a CCP must be addressed at this step or a later step. See the Meat and Poultry Hazards and Controls Guide for a list of frequently used controls. iii Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced article must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS source, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan. iv Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5."}],{"file\_name":"FSIS\_GD\_2022\_0002","title":"HACCP Model for Full Cooked-Not Shelf Stable Roast Beef","num":"FSIS-GD-2022-0002","id":"a3b881ae60480d147c8f73ad473db7713e7d8d0b6716726748541a0cbc72f319","corpus":"fsis\_guidelines","source\_page\_url":"https://www.fsis.usda.gov/policy/fsis-guidelines","url":"https://www.fsis.usda.gov/sites/default/files/media\_file/2022-04/FSIS-GD-2022-0002.pdf","type":"pdf","n\_pages":13,"word\_count":4595,"text\_by\_page":["HACCP Model for Fully Cooked\u2014Not Shelf Stable Roast Beef The United States Department of Agriculture (USDA) published the Pathogen Reduction/Hazard Analysis and Critical Control Point (HACCP) Systems Final Rule in July 1996 mandating all USDA inspected meat and poultry establishments implement a HACCP system. HACCP is a systematic and scientific method of process control for the production of safe food products. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to improve the safety

of their products. The HACCP models' focus is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic model for each food processing category defined in the regulation (9 CFR 417.2(b)(1)). The guidebook and the generic models have been revised since their initial publication to be consistent with current science and policy. FSIS recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used *in* an establishment's operation. This Fully Cooked/Not Shelf Stable HACCP model applies to products that receive a full lethality heat process step to achieve food safety. The full lethality heat process step makes these products safe to eat with no further preparation required by the consumer. However, these products are not shelf stable. Therefore, these products must be frozen or refrigerated throughout their shelf-life to maintain product safety. These products also meet the definition of ready-to-eat (RTE) product, as defined in 9 CFR 430.1. The Fully Cooked/Not Shelf Stable model's critical control points (CCPs) do not necessarily apply to all operations or products. Products or operations may require fewer or more CCPs depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The food safety critical limits selected must come from scientific documents or other reliable sources. Each model includes references for guidance on the selection of critical limits. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis, are HACCP decisionmaking records (CFR 417.5(a)). The selection of a HACCP model is a preliminary step to completing a hazard analysis. The documents produced during the selection process are HACCP records. Ensure you maintain the documents produced while developing a HACCP plan. For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage.<sup>1</sup> This information is best suited for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP model is for demonstration purposes only. The model does not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. The Guidebookisintended for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. 3Theintended use or consumer of the product must be identified in accordance with 9 CFR417.2(a)(2). Identifying the product\u2019sintended use in the product description is one way to meet the regulatory requirements specific to 417.2(a)(2). 4Each establishment may have their own defined shelf life. 5At-risk populations include young children, pregnant women, the elderly, and immunocompromised persons. 6See the FSIS Labeling Overview and Generic Label Approval guideline for information on required labeling features. Page 2 of 13", "EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING MATERIAL Process Type and Product Name: Fully Cooked\u2014Not Shelf Stable Roast Beef Meat and meat byproducts7 Fresh beef (beef eye rounds) Non-meat food ingredients Spice mixture (Sea Salt, Black Pepper, Natural Beef Stock & Flavor (Contains Smoke)) Antimicrobial interventions and processing aids8 None Packaging material Plastic vacuum bags Restricted ingredients and allergens None9 Other None DATE:

\_\_\_\_\_ APPROVED BY: 7List all meat, non-meat ingredients, restricted ingredients (for example, nitrites), processing aids, packaging material used in production of this product. This is important to help identify any special ingredients or processes to address in the HACCPplan. See the FSIS Compliance Guideline Allergens and Ingredients of Public Health Concern: Identification, Prevention and Control, and Declaration through Labeling for detailed information on allergens. To review restrictions on the use of nitrite and sodium ascorbate or sodium erythorbate, see 9 CFR 424.22(b). 8FSIS and the Food and Drug Administration (FDA) have a memorandum of understanding (MOU) that establishes the working relationship followed when responding to notifications for the use of food additives(including ingredients)intended for use in the production of FSIS regulated products. FSIS determines the suitability of the use of food ingredients used in the production of meat, poultry, and egg products. FSIS consults, as necessary, with FDA on the requirements under the Federal Food, Drug & Cosmetic Act and its implementing regulations. See FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat, Poultry and Egg Products for the list of suitable ingredients. 9With this model, the establishment does not incorporate allergenic compounds or restricted ingredients into any products and so these ingredients are not present in the facility. For that reason, this model\u2019s hazard analysis does not demonstrate controls for allergenic compounds or restricted ingredients. Review the HACCP Model for Ready-to-Eat, Heat-Treated, Shelf-Stable (Beef Jerky) to see how allergen controls might be included in a hazard analysis. Improper cooking times and temperatures could result in bacterial survival and growth. Relative humidity is addressed through the cook-in-bag process. While monitoring product temperature with a probe thermometer, the bag is punctured which exposes the product to the environment (i.e., post-lethality exposed). Product monitored with a probe thermometer is reworked and recooked before distribution per Written Rework Procedures SOP to ensure no post-lethality exposed product is in commerce. Limit heating come-up time (50°F to 130°F) to less than 6 hours to ensure S. aureus outgrowth is limited to 2 logs or less (see FSIS Revised Appendix 23, 24 A). Cook to appropriate time and temperature found in FSIS Revised Appendix A to achieve a 6.5 log<sub>10</sub> reduction of Salmonella as per performance standards in 9 CFR 318.17. 25 CCP 1 C: None 22 If the product is not cook-in-bag and the establishment uses FSIS Cooking Guideline for Meat and Poultry Products (Revised Appendix A) as support for the lethality treatment/ cooking step, relative humidity must be addressed using one of the options on page 26 of the Revised Appendix A or the establishment must provide support for why relative humidity does not need to be addressed (9 CFR 417.5(a)(1)). For a model HACCP plan that addresses relative humidity following

one of the options in the Revised Appendix A, see the HACCP Model for Ready-to-Eat, Heat-treated, Shelf-stable (Beef Jerky).<sup>23</sup> If an establishment implements a process consistent with the process specifications described in the scientific support, and the scientific support contains microbiological data specifying the level of pathogen reduction achieved by the intervention strategy for the target pathogen identified in the hazard analysis, the in-plant data collected during the 90 day initial validation period will consist of data on quantifiable characteristics of the critical operational parameters, such as pressure, temperature, and concentration. However, if an establishment implements different critical operational parameters in the process from the scientific support, or the scientific support identified does not contain microbiological data, then the establishment must collect in-plant data demonstrating the critical operational parameters that it has implemented can all be met AND should collect in-plant microbiological data or identify scientific support with microbiological data that demonstrates the effectiveness of those implemented critical operational parameters (FSIS Compliance Guideline HACCP Systems Validation, page 27).<sup>24</sup> Establishments producing products with long heating come-up-times due to product size, such as ham and beef brisket, can use the critical operating parameters found on page 48 of the FSIS Cooking Guideline for Meat and Poultry Products (Revised Appendix A). This reference can be used as support for applying FSIS<sup>u2019</sup> applicable time-temperature combinations and relative humidity, without considering heating come-up-time as a critical operating parameter.<sup>25</sup> See FSIS Cooking Guideline for Meat and Poultry Products (Revised Appendix A) for validated times and temperatures. If alternative methods are used, refer to the validation and scientific support for the alternative lethality step as described in the FSIS Compliance Guideline HACCP Systems Validation. Include critical operational parameters for lethality and stabilization in the HACCP plan. Page 9 of 13", "Step Potential Hazard RL TO Justification \ Basis Controls CCP P: None 8. Chilling B: Clostridium perfringens and Clostridium botulinum Yes Spores can survive the Cooking step (#7), germinate, and grow if not cooled quickly. Product is cook-in-bag and therefore not post-lethality exposed so Listeria monocytogenes is not a hazard of concern.<sup>26</sup> Bags that are punctured with a thermometer for monitoring are reworked and recooked before distribution per Written Rework Procedures SOP to ensure no post-lethality exposure. Chill roasts following appropriate time and temperature in FSIS Revised Appendix B to prevent multiplication of toxigenic microorganisms such as Clostridium botulinum and no more than 1 log<sub>10</sub> multiplication of Clostridium perfringens to comply with the performance standard in 27 9 CFR 318.17(a)(2). CCP 2 C: None P: None 9. Cold Storage Cooked Roasts B: Pathogen outgrowth: Clostridium perfringens and Clostridium botulinum No Written Temperature Control SOP for monitoring product temperature to prevent outgrowth of microorganisms. Once per week, a manager or designee calibrates product thermometers per manufacturer\u2019s instructions. Once per week a manager or designee will review all records maintained. Roast Beef Cooking Log from computerized continuous monitoring device Thermometer Calibration Log Direct Observation Log Records Review Log Corrective Action Log 28The cooking critical limits used in this plan are derived fromthe FSISCooking Guideline for Meatand Poultry Products (Revised Appendix A). See Appendix Afor guidance on implementing this safe harbor and foradditionalvalidated time and

temperature parameters for lethality cooking processes including parameters for products with heating come-up times (50°F to 130°F) longer than 6 hours. For general guidance on establishing critical limits, see the Guidebook for the Preparation of HACCP plans (page 27).

29 The critical limits in this model assume a thermometer with an accuracy of less than 0.1°F. Establishments producing cooked meat and poultry products should have sufficient monitoring equipment, including recording devices, to assure that the time, temperature, and relative humidity operating parameters of their processes are being met. With any monitoring equipment, the establishment should take the normal variation of the monitoring equipment into account when designing the critical limits. 30 Relative humidity is not addressed because moisture is inherently maintained around the product due to cooking in a sealed, moisture impermeable bag. 31 Establishments may also determine during the initial validation period that the worst-case scenario is the largest roast regardless of location in the oven. In that case, establishments may choose to monitor the internal temperature in the largest roast rather than a roast in the coldest spot in the oven. 32 See Revised Appendix A guidance on corrective actions to perform when a cooking deviation occurs (page 66). Page 12 of 13, "EXAMPLE ROAST BEEF HACCP PLAN Critical Control Point (CCP) Significant Hazard(s) Critical Limits for Each Control Measure Monitoring Procedures Corrective Action Verification Records What How Frequency Who CCP 2 Chilling Clostridium perfringens and Clostridium botulinum Chill product from 130°F to 80°F in 1.5 hours or less. APPROVED: \_\_\_\_\_ 33 The chilling critical limits used in this plan are Option 1.1 found in the FSIS Stabilization Guideline for Meat and Poultry Products (Revised Appendix B) (page 50). See Appendix B for additional guidance on implementing this safe harbor. Appendix B also contains additional validated chilling time and temperature stabilization methods. For general guidance on establishing critical limits see the Guidebook for the Preparation of HACCP plans (page 27). 34 Establishments may determine during the initial validation period that the worst-case scenario is the largest roast regardless of location in the cooler. In that case, establishments may choose to monitor the internal

temperature of the largest roast rather than a roast in the warmest spot in the cooler. 35 See Revised Appendix B guidance on corrective actions to perform when a cooling deviation occurs (page 71). 36 The Roast Beef Temperature Cooking and Chilling recordkeeping logs must include monitoring the interim steps for cooling (for this example: record the time required for the product to drop from 130°F to 80°F, and the time required for the product temperature to drop from 80°F to 40°F). Page 13 of

13"]}, {"file\_name": "FSIS\_GD\_2022\_0003", "title": "Self-Reporting Tool (v2022-001)", "num": "FSIS-GD-2022-0003", "id": "d4827534ed64293053c814624ab7d972bfe987b6e7a6e7fe4dc06a9817b7e395", "co\_rpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/media\_file/2022-03/Self-Reporting-Tool\_v2022-001.pdf", "type": "pdf", "n\_pages": 27, "word\_count": 14936, "text\_by\_page": ["Self-Reporting Tool (SRT; v2022-001) Self-Reporting Tool To be eligible to export meat, poultry, or egg products to the United States, countries must maintain inspection systems that achieve an equivalent level of public health protection to FSIS\u2019 inspection system. The Codex standard Guidelines on the Judgement of Equivalence of Sanitary Measures Associated with Food Inspection and Certification Systems (CAC/GL 53-2003) defines equivalence as \u201cthe state wherein sanitary measures applied in an exporting country, though different from the measures applied in an importing country, achieve, as demonstrated by the exporting country, the importing country\u2019s appropriate level of sanitary protection.\u201d This definition is consistent with the principle of equivalence as provided in the Agreement on the Application of Sanitary and Phytosanitary Measures of the World Trade Organization. Furthermore, the definition of sanitary measure in the Codex standard includes \u201call relevant laws, decrees, regulations, requirements, and procedures.\u201d Therefore, a country that wishes to export meat, poultry and egg products to the United States must provide objective data that the country\u2019s laws, regulations, requirements, and procedures provide a level of public health protection equivalent to the FSIS inspection system. If the exporting country does not have this objective data, FSIS would consider implementation of U.S. sanitary measures as a reasonable alternative to assure the eligibility of products for export to the United States. To determine whether a country\u2019s documented food safety inspection system achieves an appropriate level of public health protection, FSIS assesses the Self-Reporting Tool (SRT) responses and supporting documentation provided by the country\u2019s national government authority responsible for ensuring the safety, wholesomeness, and accurate labeling of meat, poultry, and egg products (i.e., the Central Competent Authority (CCA)). The SRT questions are based on regulatory-focused food safety objectives and reflect the equivalence criteria used by FSIS to determine whether a country\u2019s documented food safety inspection system is equivalent to the FSIS inspection system. The SRT is designed for countries that want to export the following products to the United States: meat (including beef, veal, pork, sheep including lamb and mutton, goat, and Siluriformes fish); poultry (including chickens, turkeys, ducks, geese, guineas, squabs, emu, rhea, and ostrich); or egg products (i.e., dried, frozen, or liquid eggs, with or without added ingredients). The SRT questions are arranged into six (6) components: 1. Government Oversight (e.g., Organization and Administration, Enforcement Authority, Government Inspection Personnel\u2013Training/Staffing) 2. Government Verification of Food Safety and Other

Consumer Protection Requirements (e.g., Humane Handling, Ante-mortem Inspection, Post-mortem Inspection, Product Standards and Labeling) 3. Government Sanitation Verification 4. Government Hazard Analysis and Critical Control Point (HACCP) System Verification 5. Government Chemical Residue Program 6. Government Microbiological Pathogen and Process Control Programs For FSIS to determine equivalence, the CCA must provide complete responses to all SRT questions applicable to its food safety inspection system governing the meat, poultry, or egg products the country intends to export to the United States. Complete responses include a narrative, accompanied by supporting documentation, describing how the country's food safety inspection system is implemented. In addition, SRT responses need to cite where in the supporting documentation the information can be found. For example, answers should include the page number, section number, or chapter from the relevant supporting documentation. Types of supporting documentation the CCA should provide include, but are not limited to, the following: a. Food safety and inspection laws and legislation; b. Regulations, policies, standards, decisions, annexes, and decrees; c. Inspection procedures, manuals, and directives; d. Control programs; e. Inspection training programs; f. Mechanisms for documenting compliance/noncompliance; g. Enforcement and compliance programs; and h. Government chemical residue and microbiological sampling and testing programs, and test results.", "Self-Reporting Tool (SRT; v2022-001) The following chart identifies which SRT questions the CCA needs to provide answers and supporting documentation for based on the specific products the country is eligible to export or interested in exporting to the United States. To view which products your country is currently eligible to export to the United States, refer to FSIS Import & Export Library. For more information on product categorization, refer to the FSIS Product Categorization (Import) guide. Products SRT Question Numbers Standard SRT questions to be answered for all products 1, 2, 3, 4, 5, 6, 7, 9, 13, 14, 15, 16, 18, 23, 24, 25, 26, 34 Raw-Intact and Raw-Non Intact Beef and Veal 10, 11, 12, 17, 22, 27, 28, 29 Raw-Intact and Raw-Non Intact Pork 10, 11, 12, 22, 27, 28 Raw-Intact and Raw-Non Intact Lamb, Mutton, or Goat 10, 11, 12, 17, 22, 27, 28 Raw-Intact and Raw-Non Intact Poultry and Ratites 10, 11, 12, 22, 27, 28 Raw-Intact and Raw-Non Intact Siluriformes Fish 20, 21 Thermally Processed/Commercially Sterile Meat and Poultry Products 33 Not Heat Treated-Shelf Stable Meat and Poultry Products 30, 31, 32 Heat Treated-Shelf Stable Meat and Poultry Products 30, 31, 32 Fully Cooked-Not Shelf Stable Meat and Poultry Products 30 Heat Treated-Not Fully Cooked-Not Shelf Stable Meat and Poultry Products 32 Product with Secondary Inhibitors-Not Shelf Stable Meat and Poultry Products 30, 32 Egg Products 30 The SRT provides bulleted guidance under each SRT question to aid CCAs in providing complete SRT responses that adequately demonstrate that the country's documented food safety inspection system achieves an equivalent level of public health protection to the U.S. inspection system. The bulleted information is not intended to be prescriptive in nature but rather guidance to foreign countries on the type of information CCAs should include in their responses to each individual SRT question. When responding to SRT questions, the CCA can provide responses that demonstrate that the CCA implements regulations and procedures consistent with FSIS regulations and procedures or implements alternative measures that achieve an equivalent level of public health protection. Submission of the SRT To submit the SRT and supporting documentation, the CCA can either upload the information into FSIS' webbased Public Health Information System (PHIS), or submit the SRT, including supporting documentation, to

the FSIS Office of International Coordination through e-mail at internationalcoordination@usda.gov or regular mail (1400 Independence Avenue SW, Room 3143-South Building, Washington, DC 20250). FSIS uploads and maintains all SRT answers and supporting documentation in PHIS. It is important for countries to verify the accuracy and completeness of the English translated documents in PHIS because FSIS uses the English translated version of the SRT answers and supporting documentation in PHIS when making equivalence determinations. If issues are identified during FSIS\u2019 review of the country\u2019s submitted SRT answers and supporting documentation, FSIS will send the CCA requests for information and may propose a technical call between FSIS and the CCA. Ongoing Equivalence Verification No later than May 18th of each year, the CCAs of countries wishing to maintain ongoing equivalence and 2", "Self-Reporting Tool (SRT; v2022-001) continue exporting meat, poultry, or egg products to the United States must either provide updated SRT answers, or communicate to FSIS that the SRT answers in PHIS are accurate and complete by providing an answer to SRT Question 34. Also, no later than May 18th of each year, the CCA should verify in PHIS whether the translated documents were translated correctly into English by providing an answer in SRT Question 34. Updates to the SRT are expected whenever the CCA makes changes to its food safety inspection system, including changes implemented because of new or revised FSIS policies, or in response to FSIS requests for information. In addition, the CCA must provide the following no later than May 18th of each year: 1. An up-to-date list of all certified establishments eligible to export to the United States. \u2022 For more information on how to complete and submit an up-to-date list of all establishments used in the production of products eligible to export to the United States, refer to FSIS Guidance for a Suggested Reporting Table for the Certified Establishment List. 2. An updated official government chemical residue sampling and testing program, including the previous year\u2019s chemical residue test results. \u2022 For more information on how to submit annual official government chemical residue sampling and testing plans and results and for an example of the information FSIS needs to evaluate foreign official government chemical residue sampling programs, refer to guidance documents on the Equivalence page of the FSIS website under \u201cAdditional Resources.\u201d 3. An updated official government microbiological sampling and testing program, including the previous year\u2019s test results for the following: (A) Salmonella and Campylobacter in raw meat and poultry products; (B) Listeria monocytogenes (Lm) and Salmonella in ready-to-eat (RTE) meat, poultry, and egg products; (C) food contact surfaces for Lm in certified establishments that produce post-lethality exposed RTE meat and poultry products; and (D) Shiga toxin-producing Escherichia coli (STEC) in raw beef products. NOTE: The CCA should provide indicator organism results for intestinal or fecal contamination if the official government sampling and testing program includes monitoring for indicator organisms. \u2022 For more information on how to submit annual official government microbiological sampling and testing plans and results and for an example of the information FSIS needs to evaluate foreign official microbiological sampling programs, refer to guidance documents on the Equivalence page of the FSIS website under \u201cAdditional Resources.\u201d Annually, FSIS will notify the CCAs of countries wishing to maintain ongoing equivalence and continue exporting meat, poultry, or egg products to the United States of the following: issues identified during our review of the SRT and official government microbiological and chemical residue sampling and testing programs; a summary of the previous year\u2019s point-of-entry (POE)

results; and any new FSIS policies that CCAs need to address, or information that CCAs need to include, as part of their annual update by May 18th of the following year. Additionally, at this time, FSIS will also inform CCAs which process categories, product categories, and product groups of meat, poultry, or egg products their country is eligible to export to the United States.

3", "Self-Reporting Tool (SRT; v2022-001) Component 1 Government Oversight

1. How does the CCA ensure that the laws and regulations governing meat (including beef, veal, pork, sheep, goat, and Siluriformes fish); poultry (including chickens, turkeys, ducks, geese, guineas, squabs, emu, rhea, and ostrich); and egg products inspection are enforced? To respond to this question sufficiently, the CCA must:
  - \u2022 Describe the legal framework that gives the CCA the authority and ability to administer the inspection system. Include the name of the CCA and a brief explanation of the CCA\u2019s organizational structure.
  - \u2022 Provide an organizational chart and a description of how to trace the linkage of authority from the CCA to local government inspection personnel.
  - \u2022 Describe the CCA\u2019s authority and responsibility to enforce the laws and regulations governing meat, poultry, and egg products inspection. In addition, describe the CCA\u2019s authority to require corrective actions in certified establishments and to take additional enforcement measures as appropriate.
    - o Include supporting documentation demonstrating that the CCA has an effective enforcement program that requires that certified establishments perform the following: take action to prevent product contamination, take corrective actions when insanitary conditions or contaminated products are found, and take effective preventive measures after instances of noncompliance.
    - o Include how (i.e., actions taken) and under what circumstances the CCA implements additional enforcement measures in certified establishments (e.g., withdrawal of inspection for failure to maintain a HACCP plan).
2. How does the CCA ensure that no meat, poultry, or egg products intended for export to the United States are adulterated or misbranded (i.e., properly labeled and packaged), and only eligible meat, poultry, and egg products are certified for export to the United States? To respond to this question sufficiently, the CCA must:
  - \u2022 Describe the CCA\u2019s legal authority and responsibility to ensure that adulterated or misbranded product is not prepared for export to the United States.
  - o Define adulterated and misbranded as it relates to meat, poultry, and egg products (i.e., statutory or regulatory definition).
  - o Describe how the CCA identifies misbranded or adulterated products and provide information on the enforcement activities the CCA takes when it identifies adulterated or misbranded product.
  - \u2022 Describe the CCA\u2019s authority and inspection procedures for certifying meat, poultry, or egg products for export to the United States, including evidence of a certificate procedure to meet U.S. import requirements. Furthermore, identify which type of government inspection personnel (i.e., government inspector, licensee, or contract employee)<sup>1</sup> is performing export certification procedures for product intended for export to the United States, including signing the export certificate.
  - Lastly, describe how the CCA maintains control over export certificates, stamps, and seals.
  - \u2022 Describe how and at what frequency government inspection personnel are verifying during export certification that adulterated or misbranded product is not being exported to the United States.
  - \u2022 Describe how and at what frequency government inspection personnel review and confirm acceptable testing results from all samples of products (i.e., establishment testing and government verification testing) tested for adulterants as defined by FSIS prior to signing the export certificate.

NOTE: This applies to confirmation of acceptable testing results for the following sampled products:

raw non-intact beef product or raw intact beef product intended for raw non-intact use (or where intended use is unknown) that is tested for STEC; RTE meat, poultry, and egg products tested for Lm or Salmonella, or STEC (relative to RTE beef products); RTE product that passed over food contact 1 For definitions of these terms, please refer to SRT Question 5. 4", "Self-Reporting Tool (SRT; v2022-001) surfaces that have been tested for the presence of Lm or Salmonella; and livestock carcasses and parts subjected to both routine and suspect chemical residue testing for veterinary drugs, pesticides, and environmental contaminants. \u2022 Describe the CCA\u2019s authority to recall adulterated or misbranded product. Identify whether recalls of adulterated or misbranded product are carried out by the CCA or the establishment, and identify whether the CCA maintains the authority and ability to take action if the recall is ineffective (e.g., the authority to seize product). \u2022 Describe whether recalls are carried out on adulterated or misbranded product in the distribution phase or in commerce. Additionally, describe whether the CCA requires certified establishments to notify the CCA of the production of or shipment of adulterated products within a certain time (e.g., within 24-hours). Furthermore, in the event adulterated or misbranded products are shipped to the United States, describe the CCA\u2019s procedures for informing FSIS and include a timeframe of when FSIS will be notified. 3. How does the CCA ensure that source meat, poultry, or egg products used in processing operations originate from certified establishments in countries that the United States has determined have an equivalent meat, poultry, or egg products inspection system (i.e., eligible countries)? NOTE: Source is defined as materials that originate from a certified establishment in an eligible country. To respond to this question sufficiently, the CCA must: \u2022 Describe how and at what frequency government inspection personnel verify source materials originate from a certified establishment in a country eligible to ship meat, poultry, or egg products to the United States. \u2022 Identify the source country for shell eggs used to produce egg products for export to the United States. In addition, describe the CCA\u2019s requirements for the quality and appearance of shell eggs used to produce egg products for export to the United States. 4. How does the CCA ensure that the same set of laws, regulations, and policies are applied consistently to all establishments certified to export meat, poultry, or egg products to the United States? NOTE: By May 18th of each year, the CCAs of countries wishing to maintain ongoing equivalence and continue actively exporting meat, poultry, or egg products to the United States are required to provide FSIS an up-to-date list of all certified establishments used to produce or export products to the United States. Therefore, if the production chain involves more than one establishment (e.g., beef is slaughtered at one establishment, further processed at a different establishment, packaged and labeled at yet another establishment, and then exported to the United States from a different establishment), each establishment in the production chain, including the storage facility from where the product is exported, must be listed on the certified establishment list. Furthermore, countries that are not eligible to export raw product directly to the United States (e.g., due to animal disease restrictions), but are eligible to use their own raw source materials for further processing are required to certify and list the establishments providing the raw source materials. NOTE: FSIS requests that the CCA inform FSIS of any establishment delistment within 90 days. \u2022 For more information on how to complete and submit an up-to-date list of all establishments used in the production of products eligible for export to the United States, refer to FSIS Guidance for a Suggested Reporting Table for the Certified Establishment List. NOTE: A

certified establishment is an establishment that the CCA determines as meeting U.S. requirements and, therefore, eligible to export meat, poultry, or egg products to the United States. NOTE: A decertified establishment is an establishment that the CCA determines as not meeting U.S. requirements and, therefore, not eligible to export meat, poultry, or egg products to the United States. NOTE: A source establishment is an establishment that provides raw materials to certified establishments for the production of processed products intended for export to the United States. Product from establishments that are not eligible to export product directly to the United States due to disease restrictions, regionalization, product ineligibility, or other reasons may be able to be used as a source 5", "Self-Reporting Tool (SRT; v2022-001) establishment for processed products (e.g., when product will be fully cooked to destroy causative agents related to restricted animal diseases). However, source establishments must meet all U.S. requirements, be from an equivalent country, be certified by the CCA, and be identified as a source establishment on the certified establishment list. To respond to this question sufficiently, the CCA must: \u2022 Describe how and at what frequency CCA supervisory personnel verify that certified establishments meet U.S. requirements. \u2022 Describe the processes that the CCA follows to certify establishments as meeting U.S. requirements, and to decertify establishments that no longer meet U.S. requirements. \u2022 Describe how and at what frequency the CCA disseminates information regarding U.S. requirements from headquarters to government inspection personnel and certified establishments, including how the CCA communicates any changes to U.S. requirements in a timely manner. Further, describe how the CCA remains aware of FSIS requirements as they change over time.

5. How does the CCA ensure that government inspection personnel assigned to certified establishments exporting meat, poultry, or egg products to the United States are employees of and paid by the government? NOTE: The term \u201cgovernment inspection personnel\u201d (referenced throughout this SRT) refers to inspectors meeting the criteria in a, b, or c. When responding to this SRT question, use the terms and definitions below to identify the type of government inspection personnel used in your country\u2019s certified establishments when producing product for export to the United States.

a. Government Inspector: A government inspector is a permanent or intermittent employee of the CCA of a foreign government, eligible to perform all applicable inspection duties, including: \u2022 ante-mortem inspection of livestock and poultry; \u2022 post-mortem inspection of every livestock carcass, head, and viscera and every poultry carcass and viscera; 2 \u2022 sanitation and HACCP verification activities in all meat, poultry, and egg product establishments; \u2022 export verification activities; and \u2022 official government verification sample collection activities in meat, poultry, and egg product establishments. NOTE: FSIS would recognize as government inspectors those inspectors that work for another part of the foreign government outside the CCA, but under delegated authority from the CCA, provided the CCA has authority and oversight over the inspection.

b. Licensee (Limited Government Inspector): An inspector employed under individual contract by the government and who is eligible to perform all applicable inspection duties, including: \u2022 ante-mortem inspection of livestock and poultry; \u2022 post-mortem inspection of every livestock carcass, head, and viscera and every poultry carcass and viscera; \u2022 sanitation and HACCP verification activities in all meat, poultry, and egg product establishments; 2 Under alternative poultry inspection systems, similar to FSIS\u2019 New Poultry Inspection System (NPIS), the government inspection

personnels\u2019 visual inspection of each carcass also serves as the inspection of the viscera if the inspector\u2019s condemnation of a carcass also requires condemnation of the corresponding viscera. For countries that implement an alternative poultry inspection system, provide a response that describes the requirements and procedures of your alternative poultry inspection system under Question 12. 6", "Self-Reporting Tool (SRT; v2022-001) \u2022 export verification activities; and \u2022 official government verification sample collection activities in meat, poultry, and egg product establishments. NOTE: Typically in this situation, the licensee (limited government inspector) is under direct supervision of the government, meaning that a government inspector is on the premises while licensees (limited government inspectors) are performing inspection duties (other than official government verification sample collection activities) for product intended for export to the United States continuously throughout slaughter operations and at least once per shift during processing (i.e., non-slaughter) operations and are ensuring licensees are effectively performing inspection duties. Typically, criterion b is not equivalent when a limited government inspector performs inspection activities (other than official government verification sample collection activities) without direct supervision from an onsite government inspector continuously during slaughter operations and at least once per shift during processing operations. c. Contract Employee (Private Contractor): An employee employed by a third-party organization contracted to conduct inspection activities on behalf of the government. The operator is authorized by the government to perform all applicable inspection duties, including: \u2022 ante-mortem inspection of livestock and poultry; \u2022 post-mortem inspection of every livestock carcass, head, and viscera and every poultry carcass and viscera; \u2022 sanitation and HACCP verification activities in all meat, poultry, and egg product establishments; \u2022 export verification activities; and \u2022 official government verification sample collection activities in meat, poultry, and egg product establishments. NOTE: Typically in this situation, the contract employee (private contractor) is under direct supervision of the government, meaning that a government inspector is on the premises while contract employees are performing inspection duties (other than official government verification sample collection activities) for product intended for export to the United States continuously during slaughter operations and at least once per shift during processing (i.e., non-slaughter) operations, and are ensuring contract employees are effectively performing inspection duties. Typically, criterion c is not equivalent when a contract employee performs inspection activities (other than official government verification sample collection activities) without direct supervision from an onsite government inspector continuously during slaughter operations and at least once per shift during processing operations. To respond to this question sufficiently, the CCA must: \u2022 Identify which criterion (or criteria) above applies to the government inspection personnel provided for meat, poultry, or egg products intended for export to the United States. o For countries utilizing licensees or contract employees, describe how and at what frequency the CCA ensures that inspection activities (other than official government verification sample collection activities) are being conducted under the direct authority of a government agency when producing product for export to the United States \u2022 Describe how all government inspection personnel are paid. This may include direct or indirect payment by the government, such as payment through a third party. \u2022 Describe the CCA\u2019s conflict-of-interest controls to ensure that government inspection personnel act in the public\u2019s interest. 7", "Self-Reporting Tool (SRT; v2022-001)

6. How does the CCA ensure that government inspection occurs continuously during slaughter operations, and at least once per production shift during the processing of meat, poultry, or egg products intended for export to the United States? NOTE: Processing operations include all non-slaughter activities, including but not limited to, boning, cutting, slicing, grinding, injecting, pumping, filleting, breading, adding ingredients through other mechanical means, formulating, assembling, packaging, and labeling meat or poultry food products. For egg products, processing operations include the manufacturing of egg products, including but not limited to, breaking eggs, filtering, blending, mixing, pasteurizing, stabilizing, storing, cooling, freezing, drying, packaging, labeling, and final product examination. NOTE: In slaughter operations, FSIS requires continuous government inspection during slaughter activities to ensure that every livestock carcass, head, and viscera and every poultry carcass and viscera<sup>3</sup> are inspected. NOTE: In processing operations (i.e., non-slaughter), FSIS typically requires that government inspection personnel (i.e., government inspector, licensee, or contract employee) be on the premises and performing inspection activities at least once per production shift during processing operations. The requirement for government inspection once per production shift during processing operations is not the same as inspection once daily. In processing establishments, if an establishment has more than one production shift per day during which it produces product for export to the United States, typically government inspection personnel (i.e., government inspector, licensee, or contract employee) must be present at least once during each production shift. To respond to this question sufficiently, the CCA must: \u2022 Describe how the CCA ensures that there will be enough qualified government inspection personnel to provide inspection coverage at each of the certified establishments continuously during slaughter operations, and at least once per production shift during processing operations when producing meat, poultry, or egg products for export to the United States, including during planned or unplanned government inspection personnel absences.

7. How does the CCA ensure that government inspection personnel have appropriate educational credentials, disciplinary backgrounds, and training to carry out their inspection tasks? To respond to this question sufficiently, the CCA must:

\u2022 Describe the minimum qualifications for government inspection personnel (e.g., educational credentials, training, and experience requirements), including whether official veterinarians in certified establishments are required to possess a Doctor of Veterinary Medicine or equivalent degree.

\u2022 Describe how and at what frequency government inspection personnel are trained on requirements consistent with U.S. requirements.

8. RESERVED

9. How does the CCA ensure adequate oversight of laboratories that perform analyses for official government sampling and testing programs for meat, poultry, or egg products that are exported to the United States, including oversight to ensure that laboratories conducting official government analyses comply with the general quality assurance and control criteria provided in International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC) Guide 17025? NOTE: The CCA must provide information for laboratories that perform analyses for the official government chemical residue and the official government microbiological sampling and testing programs.

3 See footnote 2 8", "Self-Reporting Tool (SRT; v2022-001)

To respond to this question sufficiently, the CCA must:

\u2022 Describe the CCA\u2019s oversight of laboratories responsible for analyzing official government samples, including whether the CCA has the legal authority and responsibility to approve and disapprove laboratories conducting testing of official government

samples of product destined for the United States. \u2022 Provide a list of laboratories that perform official government chemical residue or microbiological analyses. Identify whether laboratories conducting official government analyses are official government laboratories or third-party laboratories (e.g., international (foreign), private, or establishment laboratories) and which type of analyses are performed at each laboratory (i.e., chemical residue or microbiological). If a third-party laboratory is used, briefly describe the interaction and oversight by the government. Include documentation demonstrating that the third-party laboratory reports test results directly to the government, as well as documentation demonstrating the degree of oversight by the government, such as annual audits, to ensure laboratory procedures are followed in accordance with ISO\IEC 17025 standards. \u2022 Describe the CCA\u2019s requirements for ensuring that official laboratories implement procedures consistent with ISO\IEC 17025 standards.

- o If official laboratories are required to be accredited to ISO\IEC 17025 standards, provide accreditation certificates and scopes of accreditation for all official laboratories. \u2022 Describe the CCA\u2019s requirements for ensuring that laboratory personnel are properly trained in the chemical residue and microbiological analyses performed (ISO\IEC 17025:2017(E), Section 6.2).
- o Indicate whether official laboratories are required to monitor laboratory performance through proficiency testing or other interlaboratory comparisons (ISO\IEC 17025:2017(E), Section 7.7). \u2022 If the laboratory is not ISO-accredited, describe how laboratory management and technical requirements comply with ISO\IEC 17025 standards including the following:

- o Sample handling after collection and during transport to official laboratories;
- o Sample receipt and storage prior to analyses at the laboratory;
- o Calibration and maintenance of laboratory equipment necessary for chemical residue and microbiological analyses (ISO\IEC 17025:2017(E), Section 6.4);
- o Internal quality control parameters, including positive and negative assay controls where appropriate, to assure the quality of the results for the analyses performed (ISO\IEC 17025:2017(E), Section 7.7); and
- o Reporting and recordkeeping capabilities that can clearly track and link a test result to the correct establishment, including traceability from sample collection, to receipt by the laboratory, through reporting back to the CCA (ISO\IEC 17025:2017(E), Sections 7.5 and 8.4).

\u2022 Describe how official government test results are reported directly from the laboratory performing the analysis to the CCA in a timely manner. In addition, describe how the CCA notifies establishments when official government test results are found positive for microbiological pathogens or violative for chemical residues. \u2022 Describe how the CCA ensures that samples with violative or unacceptable test results are not resampled or retested.

Component 2 Government Verification of Food Safety and Other Consumer Protection Requirements 10. How does the CCA ensure that animals are handled and slaughtered humanely? To respond to this question sufficiently, the CCA must:

- \u2022 Identify and describe the CCA\u2019s laws and regulations requiring that livestock and poultry are handled and slaughtered humanely.
- \u2022 Describe how and at what frequency government inspection personnel verify that livestock and poultry are handled and slaughtered humanely, including how livestock are rendered insensible to pain (e.g., 9", "Self-Reporting Tool (SRT; v2022-001) stunning by captive bolt, gunshot) prior to shackling, hoisting, and cutting the animal and how and at what frequency government inspection personnel verify that birds are thoroughly bled and not breathing prior to entering the scalding.
- \u2022 Describe the enforcement actions the CCA takes when certified establishments do not comply with humane

handling and slaughter requirements. \u2022 Describe how and at what frequency the CCA verifies that certified establishments take effective corrective actions after instances of noncompliance.

11. How does the CCA ensure that government inspection personnel perform ante-mortem inspection of livestock and poultry prior to slaughter? To respond to this question sufficiently, the CCA must:

- \u2022 Identify and describe the CCA\u2019s laws and regulations for ante-mortem inspection of livestock and poultry.
- \u2022 Identify which type of government inspection personnel (i.e., government veterinarian, government inspector, licensee, or contract employee) is performing ante-mortem inspection of livestock and poultry in certified establishments, and how and at what frequency government inspection personnel verify antemortem requirements are met. Furthermore, identify whether a government veterinarian oversees antemortem verification activities.
- \u2022 Identify which ante-mortem disease conditions are condemnable.
- \u2022 Describe how and at what frequency government inspection personnel verify that dead, dying, and diseased animals, or non-ambulatory disabled cattle (including calves), are condemned and not used to manufacture meat and poultry products eligible for export to the United States.
- \u2022 Describe how and at what frequency government inspection personnel verify that cattle displaying clinical signs of central nervous system disorders or bovine spongiform encephalopathy (BSE) are condemned and not used to manufacture meat products eligible for export to the United States.

\u2022 For swine, identify whether the CCA utilizes an alternative swine slaughter inspection system similar to FSIS\u2019 New Swine Slaughter Inspection System (NSIS). If using an alternative swine slaughter inspection system, describe how and at what frequency government inspection personnel verify that certified establishments:

- o Sort fit from unfit animals prior to government ante-mortem inspection;
- o Dispose of carcasses and parts with condemnable conditions;
- o Identify animals or carcasses, that they have sorted and removed for disposal before government inspection, with a unique tag, tattoo, or similar device; and
- o Maintain records documenting the total number of animals and carcasses sorted and removed per day and the reasons for their removal.

12. How does the CCA ensure that government inspection personnel perform post-mortem inspection of every livestock carcass, head, and viscera and every poultry carcass and viscera during and after the slaughter of livestock and poultry? NOTE: In this SRT question, the term \u201con-line\u201d refers to government inspection personnel working on the production line and performing post-mortem inspection procedures on every livestock carcass, head, and viscera and every poultry carcass and viscera.<sup>4</sup> The term \u201coff-line\u201d refers to government inspection personnel performing verification activities throughout the establishment (e.g., HACCP, sanitation, zero tolerance). Off-line government inspection personnel do not remain on the production line performing inspection activities throughout the day. Off-line government inspection personnel are also referenced in SRT Question 22. To respond to this question sufficiently, the CCA must:

- 4 See footnote 2 10", "Self-Reporting Tool (SRT; v2022-001)
- \u2022 Identify and describe the CCA\u2019s laws and regulations for post-mortem inspection of every livestock carcass, head, and viscera and every poultry carcass and viscera<sup>5</sup> at the time of slaughter. Furthermore, identify which type of government inspection personnel (i.e., government inspector, licensee, or contract employee) is performing post-mortem inspection of livestock and poultry in certified establishments.
- \u2022 For livestock, describe how on-line government inspection personnel perform post-mortem inspection of every livestock carcass, head, and viscera and the point in the slaughter process where

government inspection personnel examine each carcass, head, and viscera. Include how on-line government inspection personnel perform post-mortem inspection activities to ensure that every livestock carcass, head, and viscera are free of visible fecal material, ingesta, and milk; and the actions taken when on-line government inspection personnel observe contamination (fecal, ingesta, or milk) on livestock carcasses, heads, or viscera. \u2022 For poultry, describe how on-line government inspection personnel perform post-mortem inspection of every poultry carcass and viscera.<sup>6</sup> Describe how on-line government inspection personnel verify that poultry carcasses with visible fecal contamination do not enter the chiller; and the actions taken when online government inspection personnel observe fecal contamination on poultry carcasses. \u2022 For poultry, identify whether the CCA utilizes an alternative poultry slaughter inspection system similar to FSIS\u2019 New Poultry Inspection System (NPIS). If using an alternative poultry slaughter inspection system, describe how and at what frequency government inspection personnel verify that certified establishments 1) conduct carcass and viscera sorting activities, 2) dispose of carcasses and parts with condemnable conditions, and 3) perform appropriate trimming and reprocessing tasks before carcasses are presented for government inspection. \u2022 For swine, identify whether the CCA utilizes an alternative swine slaughter inspection system similar to FSIS\u2019 New Swine Slaughter Inspection System (NSIS). If using an alternative swine slaughter inspection system, describe how and at what frequency government inspection personnel verify that certified establishments 1) prepare carcasses and parts for government post-mortem inspection (e.g., incise mandibular lymph nodes and palpate the viscera to detect the presence of animal diseases (e.g., *Mycobacterium avium*); and 2) maintain records documenting that products resulting from their slaughter operations meet the new definition of ready-to-cook (RTC) pork product, which is any slaughtered pork product sufficiently free from bile, hair, scurf, dirt, hooves, toenails, claws, bruises, edema, scabs, skin lesions, icterus, foreign material, and odor that is suitable for cooking without need of further processing. \u2022 Identify which post-mortem disease conditions are condemnable. In addition, describe how and at what frequency government inspection personnel verify the proper disposition of livestock and poultry identified with these conditions. \u2022 Describe the maximum line speed rate and government staffing standards for on-line government inspection personnel in meat and poultry slaughter establishments.

13. How does the CCA ensure that a representative of the government inspection system makes periodic supervisory visits to each certified establishment to evaluate the performance of inspection personnel? To respond to this question sufficiently, the CCA must:

\u2022 Describe how and at what frequency the CCA evaluates the performance of government inspection personnel in certified establishments, including who (level of government) conducts the performance reviews of government inspection personnel.

\u2022 Identify the inspection topics evaluated during these supervisory review visits. These visits should include reviews of government inspection personnel\u2019s knowledge of U.S. import requirements and verification of the following: animal welfare, ante-mortem, post-mortem, Sanitation Standard Operating Procedure (Sanitation SOP) and sanitation performance standards (SPS), HACCP, labeling verification, export <sup>5</sup> See footnote 2 <sup>6</sup> See footnote 2 <sup>11</sup>,"Self-Reporting Tool (SRT; v2022-001) certification, import inspection to ensure source materials originate from certified establishments in eligible countries, separation from non-certified establishments, control over condemned materials, official government sample collection practices, and enforcement of U.S.

import requirements.

14. How does the CCA ensure complete separation of certified meat, poultry, or eggs products from noncertified meat, poultry, or egg products? NOTE: Any meat, poultry, or egg products intended to be exported to the United States cannot be produced in an establishment (or part of an establishment) that is not eligible to export to the United States.

NOTE: If a certified establishment also produces meat, poultry, or egg products not intended for export to the United States, the products not intended for export to the United States must be produced separately by either time or space. To respond to this question sufficiently, the CCA must:

\u2022 Describe how the CCA ensures that meat, poultry, or egg products intended for export to the United States are produced separately (by time or space) from products not intended for export to the United States.

\u2022 Describe how and at what frequency government inspection personnel verify the separation of eligible meat, poultry, and egg products from ineligible products.

15. How does the CCA ensure that meat, poultry, and egg products intended for export to the United States meet U.S. labeling requirements?

NOTE: For labels that require FSIS approval, applications can be submitted for FSIS approval electronically through FSIS\u2019 Label Submission and Approval System (LSAS), or by completing FSIS Form 7234-1, Application for Approval of Labels, Marking or Device, and then mailing the paper form. Mailing instructions are located under Label Application Guidance on the FSIS website. For more information on U.S. labeling requirements, please refer to FSIS Compliance Guidance for Label Approval and Check List for Mandatory Features on a Label.

To respond to this question sufficiently, the CCA must:

\u2022 Describe how and at what frequency government inspection personnel perform labeling verification activities to ensure that U.S. labeling requirements are met, and all labels are accurate and truthful (e.g., verification of accurate net weights and product formulation).

\u2022 Describe how and at what frequency government inspection personnel verify that all ingredients and processing aids used in the production of product intended for export to the United States are safe and suitable for the intended use.

\u2022 Describe how and at what frequency government inspection personnel perform verification activities to ensure that allergens are clearly controlled, identified, and labeled.

NOTE: FSIS recognizes the major food allergens designated by the U.S. Food and Drug Administration\u2019s (FDA) Food Allergen Labeling and Consumer Protection Act of 2004 (FALCPA). These allergens include wheat; crustacean shellfish (e.g., crab, lobster, shrimp); eggs; fish; peanuts; milk; tree nuts (e.g., almonds, pecans, walnuts); and soybeans.

\u2022 Describe how and at what frequency government inspection personnel perform species verification activities (e.g., species verification testing or verification of product formulation).

\u2022 Describe how and at what frequency the CCA ensures that labels with special statements and claims (9 CFR 412.1(c)(3)) have been approved by FSIS before exporting products to the United States.

\u2022 Describe how the CCA ensures that meat and poultry products with a U.S. standard of identity are accurately labeled.

NOTE: For more information on the U.S. labeling requirements for standards of identity, please refer to 9 CFR 319 (meat products) and 9 CFR 381 Subpart P (poultry products), and to the FSIS Food 12", "Self-Reporting Tool (SRT; v2022-001) Standards and Labeling Policy Book.

\u2022 Describe the enforcement actions the CCA takes when certified establishments do not comply with labeling requirements.

16. How does the CCA ensure that meat, poultry, and egg products designated for export to the United States are not restricted by the USDA Animal and Plant Health Inspection Service (APHIS)?

To respond to this question sufficiently, the CCA must:

\u2022 Identify and describe any APHIS disease restrictions

for meat, poultry, or egg products that the country is currently exporting to the United States or intends to export to the United States. \u2022 Describe how the CCA is notified of updates or changes to APHIS restrictions, and how these changes are communicated to government inspection personnel in certified establishments. \u2022 Describe how government inspection personnel verify during the export certification process that APHISrestricted products are not shipped to the United States. 17. How does the CCA ensure that beef products are not contaminated with specified risk materials (SRMs) associatedwith bovine spongiform encephalopathy (BSE)? To respond to this question sufficiently, the CCA must: \u2022 Describe how the CCA defines SRMs, and identify the affected tissues. \u2022 Describe the CCA\u2019s requirements concerning the identification, removal, and disposal of SRMs. \u2022 Describe how and at what frequency government inspection personnel verify adequate identification, removal, and disposal of SRMs. 18. How does the CCA ensure control over condemned animals, which can include portions of inspected carcasses and parts, and inedible material, until destroyedor otherwise denatured? NOTE: Condemned means any animal carcass, part of an animal carcass, or animal-based product inspected and determined to be unfit for human food. NOTE: Inediblematerial includes animals condemned either at ante-mortem or post-mortem inspection, SRMs, diseased parts, tissues that are inedible by definition (e.g., tonsils and lungs), and inedible shell eggs and egg products. NOTE: The denaturing of meat, poultry, or egg products includes the addition of a chemical substance (e.g., charcoal or dye) to ensure that the products cannot be used for human food. To respond to this question sufficiently, the CCA must: \u2022 Identify and describe the CCA\u2019s laws and regulations for identifying, handling, and controlling inedible material to ensure that it is not used to manufacture meat, poultry, or egg products destined for export to the United States. \u2022 Describe how and at what frequency government inspection personnel verify that condemned and inedible material is destroyed or denatured before leaving the establishment. 19. RESERVED Component 3 Government Sanitation Verification 20. How does the CCA ensure that Siluriformes fish are raised and transported under sanitary conditions? To respond to this question sufficiently, the CCA must: 13", "Self-Reporting Tool (SRT; v2022-001) \u2022 Describe how and at what frequency the CCA verifies that Siluriformes fish intended for export to the United States are raised in a sanitary manner. Include how the CCA ensures that Siluriformes fish do not grow or live under conditions that would render the fish unsound, unwholesome, unhealthful, or otherwise inedible (e.g., pre-harvest standards). \u2022 Identify whether the CCA collects either routine or \u201cfor cause\u201d official government samples of feed, Siluriformes fish, or source water to verify that Siluriformes fish are being raised under sanitary conditions. Additionally, describe the official government sample collection procedures and sampling frequencies. If samples are not collected by the CCA (e.g., by producers or establishments), describe how and at what frequency the CCA ensures that samples are collected appropriately. Furthermore, if product sampling results indicate the conditions in which the fish were raised as the source of contamination, describe how the CCA ensures contaminated or adulterated Siluriformes fish is not used in the production of Siluriformes fish product for export to the United States. \u2022 Describe the CCA\u2019s requirements for ensuring that Siluriformes fish are transported from the point of harvest to the processing establishment in a sanitary manner, including requirements for the sanitation of containers used to transport Siluriformes fish to the establishments (e.g., a holding tank in a boat transporting live fish). \u2022 Describe

how and at what frequency the CCA verifies that Siluriformes fish are transported to the establishment in a sanitary manner. 21. How does the CCA ensure that Siluriformes fish that have died from circumstances other than under the controlled circumstances of commercial fishing are separated from eligible Siluriformes fish and fish products? To respond to this question sufficiently, the CCA must: \u2022 Describe the CCA\u2019s requirements to ensure separation between slaughtered Siluriformes fish and fish products and any fish that have died other than by slaughter. \u2022 Describe how and at what frequency government inspection personnel verify that establishments are properly identifying, sorting, and disposing of Siluriformes fish that have died from circumstances other than under the controlled circumstances of commercial fishing (e.g., dead Siluriformes fish that exhibit signs of spoilage or decomposition). 22. How does the CCA ensure that livestock and poultry are slaughtered and processed in a sanitary manner? To respond to this question sufficiently, the CCA must: \u2022 Describe the CCA\u2019s requirements for sanitary dressing of livestock and poultry throughout slaughter operations, include whether establishments are required to develop, implement, and maintain written procedures in their HACCP plans, Sanitation SOPs, or other prerequisite programs to prevent contamination of livestock carcasses and parts by enteric pathogens, fecal matter, ingesta, and milk; and poultry carcasses by enteric pathogens and fecal matter. NOTE: The term \u201csanitary dressing\u201d refers to the practice of handling carcasses by establishment employees and machinery, throughout the slaughter process, in a manner that produces a clean, safe, wholesome meat or poultry food product in a sanitary manner. \u2022 Describe how and at what frequency government inspection personnel perform sanitary dressing verification activities. \u2022 Describe how and at what frequency off-line government inspection personnel perform zero tolerance verification activities to ensure the following: livestock carcasses are free of visible fecal material, ingesta, and milk at or immediately after the final rail; head, cheek, and weasand meat are free of visible fecal material, ingesta, and milk at the end of the harvesting process (e.g., at the packaging step or when 14", "Self-Reporting Tool (SRT; v2022-001) the product is placed into a container for storage); and poultry carcasses are free of visible fecal material prior to entering the chiller. Include the point in the slaughter process where the off-line government zero tolerance verification activity is performed and the actions taken when government inspection personnel observe fecal material, ingesta, or milk on livestock carcasses, heads, or viscera; or fecal material on poultry carcasses or viscera. 23. How does the CCA ensure that the condition of certified establishments\u2019 construction, facilities, and equipment is adequate to prevent the contamination or adulteration of meat, poultry, or egg products designated for export to the United States? To respond to this question sufficiently, the CCA must: \u2022 Describe the CCA\u2019s requirements for certified establishments\u2019 construction, facilities, and equipment, including how and at what frequency government inspection personnel verify that conditions in certified establishments are sufficient to prevent product contamination or adulteration (e.g., pest management program; construction; separation of edible materials from inedible materials; employee hygiene; sanitation of equipment and utensils; adequate lighting, drainage, and ventilation; and water potability). \u2022 Describe the enforcement actions the CCA takes when certified establishments do not comply with the requirements. \u2022 Describe how and at what frequency the CCA verifies that certified establishments take effective corrective actions after instances of noncompliance. 24. How does the CCA ensure

that certified establishments develop, implement, and maintain daily preoperational and operational sanitation procedures sufficient to prevent the direct contamination or adulteration of meat, poultry, and egg products designated for export to the United States? To respond to this question sufficiently, the CCA must:

- \u2022 Describe the CCA\u2019s requirements for daily sanitation procedures sufficient to prevent direct contamination or adulteration of product, including how and at what frequency government inspection personnel verify that certified establishments develop, implement, and maintain daily pre-operational and operational sanitation procedures.
- \u2022 Identify which type of government inspection personnel (i.e., government inspector, licensee, or contract employee) is performing sanitation verification activities in certified establishments.
- \u2022 Describe the CCA\u2019s sanitation recordkeeping requirements, including a description of the records certified establishments are required to maintain to demonstrate adequate implementation of their sanitation procedures (e.g., sanitation monitoring records and corrective action records).

Furthermore, describe how and at what frequency government inspection personnel review sanitation records.

- \u2022 Describe the enforcement actions the CCA takes when certified establishments do not comply with the sanitation requirements.
- \u2022 Describe how and at what frequency the CCA verifies that certified establishments take effective corrective actions and preventive measures, as applicable, after instances of noncompliance to restore sanitary conditions.

Component 4 Government HACCP System Verification 25. How does the CCA ensure that certified establishments develop, implement, and maintain a HACCP system to ensure that food safety hazards are identified, and prevented or controlled when producing meat, poultry, or egg products for export to the United States? NOTE: For countries using HACCP to address microbiological food safety hazards when producing thermally processed\commercially sterile (TP\CS) meat and poultry products, discuss food safety controls 15", "Self-Reporting Tool (SRT; v2022-001) under this question. To respond to this question sufficiently, the CCA must:

- \u2022 Identify whether the CCA requires that each certified establishment develop, implement, and maintain a HACCP system which incorporates the seven principles of HACCP to identify, prevent, and control hazards.
  - o The seven principles of HACCP include: (1) conduct a hazard analysis; (2) identify critical control points; (3) establish critical limits for each critical control point; (4) establish critical control point monitoring requirements; (5) establish corrective actions; (6) establish record keeping procedures; and (7) establish procedures for verifying the HACCP system is working as intended.
- \u2022 Identify whether the CCA requires specific controls for relevant hazards to be incorporated in the HACCP plan as a critical control point (CCP), for example, requiring certified establishments to incorporate into their HACCP plan a post-lethality treatment used to reduce or eliminate Lm.
- \u2022 Identify whether the CCA requires certified establishments to identify and evaluate the food safety hazards that can affect the safety of their products, institute controls necessary to prevent those hazards from occurring or keep them within acceptable limits, monitor the performance of controls, and maintain records routinely.
- \u2022 Describe how and at what frequency the CCA verifies that certified establishments properly identify hazards reasonably likely to occur and develop CCPs.
- \u2022 Describe how the CCA requires and verifies that certified establishments maintain in-plant implementation data, and scientific or technical support to validate the adequacy of their HACCP systems in controlling the food safety hazards identified in the hazard analysis.
- \u2022 Describe how the CCA requires and verifies that certified establishments perform ongoing

verification activities (e.g., calibration of process monitoring equipment, direct observation of monitoring activities and corrective actions, and review of records) to ensure the adequacy of their HACCP systems. \u2022 Describe how and at what frequency the CCA conducts an ongoing review of HACCP plans and verifies the effectiveness of the HACCP plans. \u2022 Describe whether the CCA has the regulatory authority to require that certified establishments take corrective actions when a CCP does not control an identified hazard. Furthermore, describe the corrective action requirements when establishment monitoring or verification, or government verification, shows that a deviation has occurred (e.g., identify and eliminate the cause of the deviation, determine that the CCP is under control after taking corrective actions, establish measures to prevent recurrence, and ensure appropriate product disposition). \u2022 Describe how often certified establishments are required to reassess their HACCP plans and under what circumstances reassessment is required. \u2022 Describe the CCA\u2019s HACCP recordkeeping requirements, including a description of the records certified establishments are required to maintain to demonstrate adequate implementation of their HACCP systems. \u2022 Identify which type of government inspection personnel (i.e., government inspector, licensee, or contract employee) is performing HACCP verification activities in certified establishments. \u2022 Describe how and at what frequency government inspection personnel verify that certified establishments review records associated with the production of product for export to the United States to ensure that all HACCP requirements are met (e.g., all critical limits at all CCPs have been met, and any required corrective actions have been taken) prior to shipping the product into commerce (i.e., establishments conduct pre-shipment review). \u2022 Describe how and at what frequency government inspection personnel verify that certified establishments are receiving and confirming acceptable testing results from all samples (i.e., establishment testing and government verification testing) of products tested for adulterants as defined by FSIS prior to completing and signing the pre-shipment review record. NOTE: This applies to confirmation of acceptable testing results for the following sampled products: 16", "Self-Reporting Tool (SRT; v2022-001) raw non-intact beef product or raw intact beef product intended for raw non-intact use (or where intended use is unknown) that is tested for STEC; RTE meat, poultry, and egg products tested for Lm, Salmonella, or STEC (relative to RTE beef products); RTE product that passed over food contact surfaces that have been tested for the presence of Lm or Salmonella; and livestock carcasses and parts subjected to both routine and suspect chemical residue testing for veterinary drugs, pesticides, and environmental contaminants. \u2022 Describe how and at what frequency government inspection personnel perform HACCP verification activities in certified establishments (e.g., monitoring, verification, recordkeeping, corrective actions). \u2022 Describe the enforcement actions the CCA takes when certified establishments do not comply with the HACCP requirements. Component 5 Government Chemical Residue Program 26. How does the CCA ensure the implementation and maintenance of an official government chemical residue control program that prevents and controls all specific compounds of concern in the foreign country and in the United States? NOTE: The CCAs of countries wishing to maintain ongoing equivalence and continue actively exporting meat, poultry, or egg products to the United States must submit an updated official government chemical residue sampling and testing program, the previous year\u2019s residue test results, and the actions taken in response to violative findings by May 18th of each year. \u2022 For more information on how to submit annual official government chemical residue

sampling and testing plans and results and for an example of the information FSIS needs to evaluate foreign official government chemical residue sampling programs, refer to guidance documents on the Equivalence page of the FSIS website under \u201cAdditional Resources.\u201d To respond to this question sufficiently, the CCA must: \u2022 Identify and describe the CCA\u2019s official government chemical residue sampling program. Include the following: o Proposed number of samples for each production class and compound tested; o Type of tissue (e.g., muscle, liver, or kidney) and sample collection procedures for each production class and compound tested; and o Established tolerances used to take regulatory action (e.g., maximum residue limit (MRL)) for each chemical compound tested. \u2022 Describe the process and frequency of reassessment of the official government chemical residue sampling program to determine whether the production classes and compounds tested should be modified. Include the following: o Indicate whether the results from previous sampling programs are evaluated to determine when changes are required; o The rationale or criteria used to develop the proposed number of samples for each production class (e.g., statistical basis, etc.); and o The rationale or criteria used to determine whether a compound is included or removed from the testing program. \u2022 Provide the analytical methodology for each of the compounds tested as part of the official government chemical residue sampling program. For reference, current FSIS analytical methods can be found in the FSIS Chemistry Laboratory Guidebook (FSIS CLG). Include the following: o The screen method and confirmation method for each compound tested. o If a single method is used to analyze multiple compounds, provide the analytical method and the list of compounds detected by that method. \u2022 Identify whether all official government chemical residue sampling is done by government inspection personnel (i.e., government inspector, licensee, or contract employee). If official government chemical 17", "Self-Reporting Tool (SRT; v2022-001) residue sampling is performed by the establishment, please include a description of how and at what frequency the CCA verifies that samples are collected appropriately. \u2022 Describe how the CCA ensures that lotting procedures are defined so that if there is a violative sample result, all affected product can be identified. \u2022 Confirm whether the CCA requires individual livestock carcasses subjected to routine official government chemical residue testing to be held pending acceptable test results when used for product intended for export to the United States. \u2022 Describe how the CCA reviews official government chemical test results to ensure that product intended for export to the United States does not contain a chemical residue that exceeds an established U.S. tolerance, or contain a chemical compound with no approved use in the production class tested. For reference, information regarding FSIS\u2019 current sampling and testing plan for chemical residues can be found on the FSIS Sampling Program web page under the \u201cAnnual Sampling Reports\u201d section; the acceptable tolerance levels set by the United States Food and Drug Administration for veterinary drugs can be found at Title 21 CFR 556; and the acceptable tolerance levels set by the United States Environmental Protection Agency for pesticides can be found at 40 CFR 180. NOTE: Generally, if there is no U.S. tolerance set for a specific chemical residue, FSIS would consider the product adulterated if any level is detected. However, there are some chemical residues, such as environmental or industrial contaminants including heavy metals, where no tolerances are set, but FSIS evaluates detection of the chemical residue on a case-by-case basis to determine if the level of contaminant in the product may render it injurious to health and thus adulterated. \u2022 Describe how the CCA

notifies establishments when an official government chemical residue result exceeds established criteria, including when the result for product intended for export to the United States exceeds an established U.S. tolerance, or contains a chemical compound with no approved use in the production class tested. \u2022 Describe the enforcement actions the CCA takes when an official government chemical residue result exceeds established criteria, including when the result for product intended for export to the United States exceeds an established U.S. tolerance or contains a chemical compound with no approved use in the production class tested. \u2022 Describe how and at what frequency the CCA verifies that certified establishments take effective corrective actions when established chemical residue criteria are not met.

Component 6 Government Microbiological Pathogen and Process Control Programs

27. How does the CCA ensure that a slaughter establishment\u2019s microbiological sampling and testing program for meat and poultry verifies process control using microbiological analyses for indicators of intestinal and fecal contamination? NOTE: The CCAs of countries wishing to maintain ongoing equivalence and continue actively exporting meat or poultry products to the United States should provide indicator organism results for intestinal or fecal contamination if the official government sampling and testing program includes monitoring for indicator organisms. If applicable, submit your updated official government microbiological sampling and testing program for indicator organisms and the previous year\u2019s test results by May 18th of each year.

\u2022 For more information on how to submit annual official government microbiological sampling and testing plans and results and for an example of the information FSIS needs to evaluate foreign official microbiological sampling programs, refer to guidance documents on the Equivalence page of the FSIS website under \u201cAdditional Resources.\u201d To respond to this question sufficiently, the CCA must:

\u2022 Describe how the CCA requires and verifies process control in certified slaughter establishments.

\u2022 Identify whether sampling for microbiological indicators of process control is done by government inspection personnel (i.e., government inspector, licensee, or contract employee). If official government 18", "Self-Reporting Tool (SRT; v2022-001) sampling is performed by the establishment, include a description of how and at what frequency the CCA verifies that samples are collected appropriately.

\u2022 Identify and describe the CCA\u2019s testing requirements for using indicator organisms to monitor process control in certified establishments. Include the following:

- o Microbiological indicator chosen;
- o Frequency of sampling;
- o Points in the process where sampling will occur (e.g., pre-evisceration, pre-chill, or post-chill);
- o Sampling methodology; and
- o Process control criteria used to evaluate the results.

\u2022 Identify whether the microbiological methods of analysis used for official government samples of indicator organisms conform to FSIS Microbiology Laboratory Guidebook (FSIS MLG) methods or internationally recognized method standards (e.g., ISO methods for Enterobacteriaceae or generic E. coli).

NOTE: If the official method includes the use of a commercial detection kit, the commercial detection kit must have been validated by an external validating organization such as Association of Analytical Communities (AOAC), Association Fran\u00e7aise de Normalisation (AFNOR), NordVal, Microval, or Spanish Association for Standardization and Certification (AENOR).

\u2022 Describe the CCA\u2019s requirements for maintaining process control records for monitoring of indicators of intestinal and fecal contamination.

\u2022 Describe how and at what frequency government inspection personnel verify that certified establishments restore process control when performance

criteria are exceeded. \u2022 Describe the enforcement actions the CCA takes when established microbiological criteria are not met. \u2022 Describe how and at what frequency the CCA verifies that certified establishments take effective corrective actions when established microbiological criteria are not met.

28. How does the CCA ensure the reduction of Salmonella in raw meat and poultry products, and Campylobacter in raw poultry products through sampling and other verification activities? NOTE: The CCAs of countries wishing to maintain ongoing equivalence and continue actively exporting meat or poultry products to the United States must submit an updated official government microbiological sampling and testing program for Salmonella and Campylobacter in raw meat and poultry products, and the previous year\u2019s test results by May 18th of each year. \u2022 For more information on how to submit annual official government microbiological sampling and testing plans and results and for an example of the information FSIS needs to evaluate foreign official microbiological sampling programs, refer to guidance documents on the Equivalence page of the FSIS website under \u201cAdditional Resources.\u201d To respond to this question sufficiently, the CCA must:

\u2022 Describe how and at what frequency the CCA verifies that establishments reduce and control Salmonella in raw meat and poultry, and Campylobacter in raw poultry.

\u2022 Describe the CCA\u2019s requirements for poultry on-line reprocessing (OLR) and poultry off-line reprocessing (OFLR). Furthermore, if antimicrobial interventions are used during poultry reprocessing, describe the antimicrobial interventions used, and explain how the CCA ensures that these antimicrobial interventions are suitable for purpose, safe, and effective.

\u2022 Describe how and at what frequency the CCA verifies that all poultry carcasses, parts, and giblets are chilled immediately after slaughter operations so that there is no outgrowth of pathogens, unless such poultry is frozen or cooked immediately at the establishment.

\u2022 For poultry, identify whether the CCA requires establishments to develop, implement, and maintain written procedures for chilling in their HACCP plans, Sanitation SOPs, or other prerequisite programs that address the potential for pathogen outgrowth, the conditions affecting carcass chilling, and the length of time necessary for adequate chilling. In addition, describe how and at what frequency government inspection personnel verify that certified establishments develop, implement, and maintain these procedures in their HACCP plans, Sanitation SOPs, or other prerequisite programs.

19", "Self-Reporting Tool (SRT; v2022-001)

\u2022 Describe how the CCA provides for an official government microbiological sampling and testing program for Salmonella in raw meat and poultry, and for Campylobacter in raw poultry. Include the following:

- o Provide a written sampling plan with instructions for sample collection and testing. When describing the sampling program for Salmonella and Campylobacter in raw meat and/or poultry products, describe the following: \uf0a7 Frequency of sampling; \uf0a7 Points in the process where sampling will occur; and \uf0a7 Sampling methodology.
- o Describe the CCA\u2019s performance standard criteria for evaluation of Salmonella and Campylobacter results, including how the CCA assesses on an ongoing basis whether certified establishments meet such performance standards for poultry: carcasses (young chicken and turkey), chicken parts, and comminuted poultry (from chicken and turkey).
- o Describe the CCA\u2019s performance standard criteria for evaluation of Salmonella results, including how the CCA assesses on an ongoing basis whether certified establishments meet such performance standards for raw meat: carcasses (cow/bull, steer/heifer) and raw ground beef.

\u2022 Identify whether official government sampling for Salmonella and/or Campylobacter in raw

meat and poultry products is done by government inspection personnel (i.e., government inspector, licensee, or contract employee). If official government sampling is performed by the establishment, include a description of how and at what frequency the CCA verifies that samples are collected appropriately. \u2022 Identify whether the microbiological methods of analysis used for official government samples of *Salmonella* and *Campylobacter* conform to FSIS MLG methods or internationally recognized method standards (e.g., ISO methods). Additionally, identify any circumstances where culture confirmation is not performed on screen positive results from samples collected as part of official government microbiological sampling, and how the CCA will respond to a screen positive result if culture confirmation is not performed. NOTE: If the official method includes the use of a commercial detection kit, the commercial detection kit must have been validated by an external validating organization such as AOAC, AFNOR, NordVal, Microval, or AENOR. \u2022 Describe the enforcement actions the CCA takes when performance standard criteria are not met. \u2022 Describe how and at what frequency the CCA verifies that certified establishments take effective corrective actions when performance standard criteria are not met, including whether the CCA conducts follow-up sampling.

29. How does the CCA ensure through sampling and other verification activities that raw beef products are free of STEC at the end of the production process? NOTE: The CCAs of countries wishing to maintain ongoing equivalence and continue actively exporting beef products to the United States must submit an updated official government microbiological sampling and testing program for STEC, and the previous year\u2019s STEC test results by May 18th of each year.

\u2022 For more information on how to submit annual official government microbiological sampling and testing plans and results and for an example of the information FSIS needs to evaluate foreign official microbiological sampling programs, refer to guidance documents on the Equivalence page of the FSIS website under \u201cAdditional Resources.\u201d To respond to this question sufficiently, the CCA must:

- \u2022 Identify whether the CCA considers STEC an adulterant in raw non-intact beef products (e.g., raw ground beef products) or raw beef products intended for raw non-intact use (e.g., beef manufacturing trimmings and other raw ground beef components such as head meat, cheek meat, weasand meat, heart meat, and product from advanced meat recovery systems (AMR)).
- \u2022 Describe how and at what frequency government inspection personnel verify that certified establishments producing raw beef products adequately address STEC in their HACCP plans, Sanitation SOPs, or prerequisite programs.

20", "Self-Reporting Tool (SRT; v2022-001)

\u2022 Describe the official government microbiological sampling and testing programs for (1) *Escherichia coli* (*E. coli*) O157:H7 and non-O157 STEC (O26, O45, O103, O111, O121, and O145) in beef manufacturing trimmings, and (2) *E. coli* O157:H7 in raw ground beef products and other raw ground beef components.

Include the following:

- o Provide a written official government sampling plan with instructions for sample collection and testing. When describing the official government STEC sampling verification program, describe the following: \uf0a7 Frequency of sampling; \uf0a7 Points in the process where sampling will occur; \uf0a7 Sampling methodology; NOTE: For analyses of raw beef products using an N60 sampling method, confirm that the entire sample is analyzed, not just a portion of the N60 trim pieces equaling a specific weight (e.g., 325g or 375g).
- \uf0a7 Target pathogens for each analysis; and \uf0a7 Criteria used to evaluate the results.

\u2022 Identify whether official government sampling for (1) *E. coli* O157:H7 and non-O157 STEC (O26, O45, O103, O111, O121, and O145) in beef manufacturing trimmings, and (2) *E. coli* O157:H7 in

raw ground beef products and other raw ground beef components is done by government inspection personnel (i.e., government inspector, licensee, or contract employee). If official government sampling is performed by the establishment, include a description of how and at what frequency the CCA verifies that samples are collected appropriately. \u2022 Identify whether the microbiological methods of analysis used for official government samples of *E. coli* O157:H7 or non-O157 STEC conform to FSIS MLG methods or internationally recognized method standards. Additionally, identify any circumstances where culture confirmation is not performed on screen positive results from samples collected as part of official government microbiological sampling, and how the CCA will respond to a screen positive result if culture confirmation is not performed. NOTE: If the official method includes the use of a commercial detection kit, the commercial detection kit must have been validated by an external validating organization such as AOAC, AFNOR, NordVal, Microval, or AENOR.

- o Describe which STEC characteristics are used to define adulterants (e.g., presence\absence of virulence genes (stx, eae), O-antigens).
- \u2022 Describe how the CCA ensures that lots are defined to establish microbiological independence so that if there is a positive sample result, all affected product can be identified.
- \u2022 Indicate whether the CCA requires establishments to sample and test raw beef products for STEC. If so, describe how and what frequency government inspection personnel verify that establishments collect samples appropriately.
- \u2022 Describe the enforcement actions the CCA takes when *E. coli* O157:H7 and non-O157 STEC positive test results are found through official government or establishment microbiological sampling programs.
- o Identify whether the CCA verifies that establishments define, investigate, and respond to recurring positives (i.e. periods of time in which slaughter establishments experience a high rate of positive results for STEC in production lots containing the same source materials).
- \u2022 Describe how and at what frequency the CCA verifies that certified establishments take effective corrective actions to prevent recurrence of STEC in response to positive samples from official government or establishment testing. For example, verification activities can include: increased frequencies of inspector verification tasks (e.g., increased sanitary dressing verification); follow-up sampling and testing; or routine sampling and testing of every lot for the presence of STEC.
- o If the CCA requires follow-up sampling, provide the frequency and duration of the follow-up sampling, and identify whether the CCA or the establishment conducts the follow-up sampling. If the CCA requires the establishment to collect follow-up samples, describe how and at what frequency the CCA verifies that the establishment conducts sampling and that results are acceptable.
- \u2022 Identify any additional STEC controls required and verified by the CCA in establishments producing raw 21", "Self-Reporting Tool (SRT; v2022-001) beef products intended for export to the United States.

30. How does the CCA ensure through sampling and other verification activities that RTE meat, poultry, and egg products are not contaminated with microbiological pathogens or their toxins, including *Lm* and *Salmonella*? NOTE: RTE products are meat, poultry, or egg products that are edible without further preparation to achieve food safety. NOTE: RTE products may include products produced under the following HACCP categories: Not Heat Treated-Shelf Stable; Heat Treated-Shelf Stable; Fully Cooked-Not Shelf Stable; Products with Secondary Inhibitors-Not Shelf Stable. For more information on how FSIS defines these HACCP process categories, refer to the FSIS Product Categorization (Import) guide. NOTE: The CCAs of countries wishing to maintain ongoing equivalence and continue actively exporting meat, poultry, or egg products to the

United States must submit an updated official government microbiological sampling and testing program for Lm, Salmonella, and other pathogens of concern in RTE product, and the previous year's residue test results by May 18th of each year. For more information on how to submit annual official government microbiological sampling and testing plans and results and for an example of the information FSIS needs to evaluate foreign official microbiological sampling programs, refer to guidance documents on the Equivalence page of the FSIS website under Additional Resources.

To respond to this question sufficiently, the CCA must:

- \u2022 Identify whether the CCA considers RTE product containing Lm, Salmonella, or other pathogens (e.g., STEC in dry, semi-dry, or fermented beef products); and RTE product that comes into direct contact with a food contact surface (FCS) contaminated with Lm or Salmonella, to be adulterated.
- \u2022 Describe how the CCA enforces a zero tolerance approach to control Lm, Salmonella, and other pathogens in RTE product destined for export to the United States. NOTE: FSIS considers all RTE products to be adulterated if they contain pathogens of public health concern (depending on the type and level) or their toxins that can cause illness in humans. There are some pathogens where any level would make the product adulterated (e.g., Lm, Salmonella, and STEC) because it would be injurious to health. Other pathogens are only a public health concern when multiplication occurs at levels that could lead to toxin formation (e.g., Clostridium perfringens (*C. perfringens*), and Clostridium botulinum (*C. botulinum*)).
- \u2022 Identify whether the CCA maintains laws, regulations, or inspection procedures regarding high pressure processing (HPP) operations that apply lethality treatments to products intended for export to the United States. For reference, HPP is an antimicrobial treatment that is capable of either reducing or eliminating biological food safety hazards on meat, poultry, or egg products. For meat and poultry products:

\u2022 Describe the CCA's government verification activities for certified establishments producing RTE meat and poultry products, including the following:

- o Describe how and at what frequency government inspection personnel verify that certified establishments adopt Listeria control measures.
- o Describe how and at what frequency government inspection personnel review and verify that certified establishments implement testing for Lm or Listeria species as an indicator for Lm based on risk, including verifying sampling procedures, testing methods, and testing results.
- o Describe how and at what frequency government inspection personnel verify that certified establishments producing RTE meat and poultry products implement control measures to prevent adulteration of both post-lethality exposed RTE products and non-post-lethality exposed RTE products. Include how and at what frequency government inspection personnel verify that certified establishments identify and implement procedures in their HACCP plans, Sanitation SOPs, or other prerequisite programs to control pathogens of concern in RTE product.
- o Describe how and at what frequency government inspection personnel verify that certified establishments are meeting lethality and stabilization requirements for RTE products. Include whether the CCA maintains performance standard requirements for pathogens or their toxins in RTE meat and poultry products (e.g., at least a 6.5-log reduction in Salmonella in cooked beef products, at least a 7-log reduction in Salmonella in cooked poultry products, and no more than a 1-log multiplication of *C. perfringens* and no multiplication of *C. botulinum* in RTE meat and poultry products).

\u2022 Describe the CCA's official government sampling verification activities for Lm and Salmonella in RTE products exported to the United States. Include the following:

- o Provide a

written sampling plan with instructions for sample collection and testing. When describing the sampling program for RTE products describe the following: \uf0a7 Frequency of sampling; \uf0a7 Points in the process where sampling will occur; \uf0a7 Sampling methodology; \uf0a7 Target pathogens for each analysis; and \uf0a7 Criteria used to evaluate the results. \u2022 Describe official government sampling verification procedures for Lm on food contact and environmental (non-food contact) surfaces in certified establishments producing post-lethality exposed RTE meat and poultry products. Include the frequency of sampling and the sampling methodology. \u2022 Describe how the CCA ensures that both post-lethality exposed and non-post-lethality exposed (e.g., cook-in-bag) RTE meat and poultry products are included in its official government sampling program. \u2022 Describe how the CCA ensures that lots are defined to establish microbiological independence so that if there is a positive sample result, all affected product can be identified. \u2022 Identify whether official government sampling for Lm and Salmonella in RTE products or the RTE production environment is done by government inspection personnel (i.e., government inspector, licensee, or contract employee). If official government sampling is performed by the establishment, include a description of how and at what frequency the CCA verifies that samples are collected appropriately. \u2022 Identify whether the microbiological methods of analysis used for official government samples of Lm and Salmonella conform to FSIS MLG methods or internationally recognized method standards. Additionally, identify any circumstances where culture confirmation is not performed on screen positive results from samples collected as part of official government microbiological sampling, and how the CCA will respond to a screen positive result if culture confirmation is not performed. NOTE: If the official method includes the use of a commercial detection kit, the commercial detection kit must have been validated by an external validating organization such as AOAC, AFNOR, NordVal, Microval, or AENOR. \u2022 Describe the enforcement actions the CCA takes when insanitary conditions or Lm, Salmonella, or other pathogens of public health concern are found through official government or establishment microbiological sampling programs. \u2022 Describe how and at what frequency the CCA verifies that certified establishments take effective corrective actions when insanitary conditions or Lm, Salmonella, or other pathogens of public health concern are found through official government or establishment microbiological sampling programs. For example, verification activities can include: increased frequencies of inspector verification tasks (e.g., increased sanitation or HACCP verification); follow-up sampling and testing; and routine sampling and testing of every lot for the presence of Lm and Salmonella. o If the CCA requires follow-up sampling, provide the frequency and duration of the follow-up sampling, and identify whether the CCA or the establishment conducts the follow-up sampling. If the CCA requires the establishment to collect follow-up samples, describe how and at what frequency the CCA verifies that the establishment conducts sampling and that results are acceptable. For egg products: \u2022 Describe how the CCA ensures that establishments implement time and temperature parameters for 23", "Self-Reporting Tool (SRT; v2022-001) cooling, pasteurization, or other heat treatments that are effective in eliminating microbiological hazards in egg products intended for export to the United States. \u2022 Describe the official government microbiological sampling and testing program for Salmonella and Lm in pasteurized liquid, frozen, and dried egg products in certified egg product establishments. Include the following: o Provide a written sampling plan with instructions for sample collection and testing. When describing the sampling program for egg

products, describe the following: \uf0a7 Frequency of sampling; \uf0a7 Points in the process where sampling will occur; \uf0a7 Sampling methodology; \uf0a7 Target pathogens for each analysis; and \uf0a7 Criteria used to evaluate the results. \u2022 Identify whether official government sampling for Salmonella and Lm in pasteurized liquid, frozen, and dried egg products is done by government inspection personnel (i.e., government inspector, licensee, or contract employee). If official government sampling is performed by the establishment, include a description of how and at what frequency the CCA verifies that samples are collected appropriately. \u2022 Identify whether the microbiological methods of analysis used for official government samples of Lm and Salmonella conform to FSIS MLG methods or internationally recognized method standards. Additionally, identify any circumstances where culture confirmation is not performed on screen positive results from samples collected as part of official government microbiological sampling, and how the CCA will respond to a screen positive result if culture confirmation is not performed. NOTE: If the official method includes the use of a commercial detection kit, the commercial detection kit must have been validated by an external validating organization such as AOAC, AFNOR, NordVal, Microval, or AENOR. \u2022 Describe whether the CCA requires certified egg product establishments to develop and implement Salmonella sampling programs for pasteurized liquid, frozen, and dried egg products. Describe how and at what frequency the CCA verifies establishment sampling and testing procedures and results. \u2022 Describe how the CCA ensures that lotting procedures are defined to establish microbiological independence of production lots so that if there is a positive sample result, all affected product can be identified. \u2022 Describe the enforcement actions the CCA takes when Lm or Salmonella positive test results are found through results are found through official government or establishment microbiological testing programs. \u2022 Describe how and at what frequency the CCA verifies that certified establishments take effective corrective actions to prevent recurrence of Lm or Salmonella in response to positive samples from official government or establishment testing.

31. How does the CCA ensure that RTE shelf-stable meat and poultry products that do not rely on cooking alone to achieve lethality, such as fermented, acidified, salt-cured or dried meat and poultry products, achieve adequate lethality and shelf-stability to prevent contamination with microbiological pathogens or their toxins (e.g., Salmonella, Lm and STEC (in beef products), C. perfringens, C. botulinum, and *Staphylococcus aureus* (*S. aureus*))?

NOTE: This question applies to products produced under the Heat Treated-Shelf Stable or Not Heat Treated-Shelf-Stable HACCP categories. For more information on how FSIS defines these HACCP process categories, refer to the FSIS Product Categorization (Import) guide. To respond to this question sufficiently, the CCA must:

\u2022 Provide all supporting documentation, including inspection procedures and frequencies, used by the CCA to verify the following:

- o At least a 5-log reduction in Salmonella and STEC (for products containing beef), and sufficient reductions in Lm during lethality;
- o The prevention of the growth of spore-forming bacteria (i.e., C. perfringens and C. botulinum) by 24", "Self-Reporting Tool (SRT; v2022-001) maintaining critical operational parameters (low pH, relatively low water activity); and
- o The prevention of the growth of *S. aureus* during the processing and no growth of *S. aureus* during the storage of shelf stable product (pH, water activity, etc.).

32. How does the CCA ensure that heat-treated NRTE meat and poultry products are properly stabilized to prevent outgrowth of microbiological pathogens or their toxins (i.e., C. perfringens and C. botulinum), and properly labeled to ensure adequate cooking by the consumer?

NOTE:

NRTE products are meat and poultry products that may or may not have received an adequate lethality treatment for *Salmonella*, and may appear RTE (e.g., chicken kiev). Furthermore, products that receive a full lethality treatment may be classified as NRTE product if they are not defined by a standard of identity to be fully cooked (e.g., hotdogs or barbecue) and are not edible without further preparation to achieve food safety. NOTE: NRTE products may include products produced under the following HACCP categories: Not Heat Treated-Shelf Stable; Heat Treated-Shelf Stable; Heat Treated but not Fully Cooked-Not Shelf Stable; Products with Secondary Inhibitors-Not Shelf Stable. For more information on how FSIS defines these HACCP process categories, refer to the FSIS Product Categorization (Import) guide. To respond to this question sufficiently, the CCA must:

\u2022 Describe how and at what frequency the CCA verifies that certified establishments are properly stabilizing and preventing the growth of spore-forming bacteria (i.e., *C. perfringens* and *C. botulinum*) in NRTE product intended for export to the United States.

\u2022 Describe how and at what frequency the CCA verifies that NRTE products are labeled with safe handling instructions and NRTE products that are not shelf-stable are labeled with special handling statements, such as keep refrigerated or keep frozen.

NOTE: For more information on the U.S. labeling requirements for safe handling instructions and special handling statements, refer to 9 CFR 317.2(k) and (l) (meat products) and 9 CFR 381.125(a) and (b) (poultry products).

33. How does the CCA ensure that the processing of canned meat and poultry products addresses *C. botulinum* and the finished products are commercially sterile? NOTE: Address the types of processing systems your country uses to produce thermally processed\commercially sterile (TP\CS) meat or poultry products for export to the United States (e.g., batch steam still, batch steam agitating, continuous rotary, hydrostatic, batch still pressure processing in water, batch agitating pressure processing in water, pressure processing with steam\air mixture in batch retorts, atmospheric cookers, and other systems such as cascading water or aseptic systems). NOTE: FSIS considers the implementation of requirements consistent with the FSIS canning regulations (see 9 CFR 431) as providing an equivalent level of sanitary protection when producing TP\CS meat and poultry products for export to the United States. NOTE: For countries using HACCP to address all food safety hazards during thermal processing\ commercial sterilization, describe your country\u2019s food safety controls under SRT Question 25. To respond to this question sufficiently, the CCA must:

\u2022 Describe how and at what frequency the CCA ensures that certified establishments producing TP\CS products for export to the United States address *C. botulinum*, incipient spoilage (i.e., spoilage occurring before the thermal process is initiated), post-processing contamination, and non-pathogenic spores (e.g., thermophilic spoilage) that are a source of abnormal containers. Furthermore, include any strategies for reducing or eliminating these hazards.

\u2022 Describe how and at what frequency the CCA verifies adequate thermal processing and commercial sterility of containers for the following:

- o For low-acid products (i.e., a canned product in which any component has a pH value above 4.6), 25", "Self-Reporting Tool (SRT; v2022-001) the process achieves a probability of  $10^{-9}$  that there are spores of *C. botulinum* in a container of the product that are capable of growing, or, a 12D reduction of *C. botulinum*, assuming an initial load of \u2264 1000 spores per container.
- o For acidified low-acid products (i.e., a canned product which has been formulated or treated so that every component of the finished product has a pH of 4.6 or lower within 24 hours after the completion of the thermal process) or products in which pathogen growth is controlled by

factors other than thermal or other sporicidal processing, the process prevents multiplication of C. botulinum in the food under the conditions in which the food is stored, distributed, and held.

- o All products are rendered free of microorganisms capable of growing in the product at nonrefrigerated conditions (over 50°F or 10°C) at which the product is intended to be held during distribution and storage (e.g., process schedules ensure at least a 5D reduction of C. sporogenes). \u2022 Describe how and at what frequency the CCA verifies that establishments certified to export TP\CS meat and poultry products to the United States address the following:

  - o Containers are airtight (hermetically sealed) and protect the contents of the container against the entry of microorganisms during and after processing;
  - o Containers and closures are cleaned and examined prior to filling; stored and handled in a sanitary manner; and examined prior to closure (e.g., visual, teardown, or physical examination) by trained closure technicians;
  - o Process schedules are developed by a processing authority prior to the processing of canned product for export to the United States;
  - o Critical factors specified in the process schedule are measured, controlled, and recorded (e.g., initial temperature, retort processing time and temperature);
  - o Operations in thermal processing areas include the posting of process schedules; development of a retort traffic control system to prevent product from bypassing the retort, along with placement of heat sensitive indicators to indicate adequate thermal processing; determination and recording of initial temperature at the start of the processing cycle; accuracy of timing devices (e.g., analog and digital clocks); and measurement of pH with a pH meter;
  - o Equipment and procedures for heat processing systems include:

    - \uf0a7 Instruments and controls common to different thermal processing systems (e.g., indicating temperature devices, temperature\time recording devices, steam controllers, air valves, and water valves);
    - \uf0a7 Engineering design standards for each retort used (e.g., batch steam still, batch steam agitating, continuous rotary, hydrostatic, batch still pressure processing in water, batch agitating pressure processing in water, pressure processing with steam\air mixture in batch retorts, atmospheric cookers, and other systems such as cascading water or aseptic systems);
    - \uf0a7 Examinations of all instrumentation and controls upon installation, on an annual basis, and following an extended shutdown to ensure the design of all equipment, instrumentation, and controls is sound, and that equipment maintenance is up-to-date;
    - \uf0a7 The recording and retention of maintenance records;
    - \uf0a7 Requirements for container cooling and cooling water, both single pass and recycled or reused cooling water (e.g., potable, chlorinated, cooling canals cleaned at an adequate frequency to prevent insanitary conditions); and
    - \uf0a7 Handling processed containers in a manner that will prevent damage to the hermetic seal area.

- o Processing and production records include, at a minimum, the date of production; product name and style; container code; container size and type; the process schedule, including the minimum initial temperature; measurement of critical factors, and record requirements specific to each retort type;
- o Certified establishments maintain records, including but not limited to, thermal process records, critical factor control records, closure evaluation records, and records associated with the development of the process schedule (e.g., venting schedules, heat distribution data, heat penetration data); 26", "Self-Reporting Tool (SRT; v2022-001)
- o Records review and maintenance includes reviewing processing records and container closure records; maintaining records identifying initial distribution of the product; and retaining processing and production records;
- o Processing deviations identified in-process or through record review are handled according to the

establishment\u2019s HACCP plan, or alternative documented procedures to ensure that TP\CS product being exported to the United States is safe for human consumption and shelf-stable; o Finished product inspections are conducted to ensure that only normal appearing containers are exported to the United States; and o Direct supervisors of thermal processing operators and closure technicians possess knowledge and training specific to canning operations. \u2022 Describe the enforcement actions taken by the CCA in response to processing deviations (i.e., deviation identified in process or through records review), including how the CCA controls TP\CS products identified to be abnormal, under-processed, or contaminated post-processing. In addition, describe how the CCA verifies corrective actions. 34. Has the CCA reviewed the SRT responses and supporting documentation in PHIS for accuracy and completeness, including all English translated documents, as part of its annual update by May 18th of each year? NOTE: In the SRT response to this question, verify whether your country\u2019s current SRT responses and supporting documentation in PHIS are accurate and up-to-date, including whether translated documents were correctly translated into English. Countries unable to access PHIS can contact the FSIS Office of International Coordination through e-mail at [internationalcoordination@usda.gov](mailto:internationalcoordination@usda.gov) to obtain copies of English translated documents for review. NOTE: All translated documents will be uploaded for review in the document section of PHIS with the word TRANSLATED in all capital letters at the beginning of the title. 35. For countries requesting a reinstatement of equivalence, initial equivalence, or expansion of equivalence, identify the process category, product category, product group, and species that your country intends to export to the United States. NOTE: For more information, refer to FSIS Product Categorization (Import) guide.

27"]}, {"file\_name": "FSIS\_GD\_2022\_0004", "title": "HACCP Model for Raw Non-Intact Egg Products", "num": "FSIS-GD-2022-0004", "id": "a9bf2768d222d60124de42692261a8f988f6690a2816e937a73b8756b8aada7e", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/media\_file/2022-06/FSIS-GD-2022-0004.pdf", "type": "pdf", "n\_pages": 14, "word\_count": 3537, "text\_by\_page": ["HACCP Model for Unpasteurized Liquid Egg (Raw Non-Intact Processing Category) The United States Department of Agriculture (USDA) published the Pathogen Reduction\Hazard Analysis and Critical Control Point (HACCP) Systems Final Rule (PR\HACCP rule) in July 1996, mandating all USDA inspected meat and poultry establishments implement a HACCP system. Hazard Analysis and Critical Control Point (HACCP) is a systematic and scientific method of process control for the production of safe food products. The HACCP regulations (9 CFR Part 417) required meat and poultry establishments to develop and implement a system of controls designed to improve the safety of their products. The HACCP models\u2019 focus is on product safety, not product quality characteristics. On October 29, 2020, the USDA published a final rule that updated the egg products inspection regulations. The USDA amended the egg products inspection regulations to require official plants that process egg products to develop and implement Sanitation Standard Operating Procedures (Sanitation SOPs) to meet other sanitation requirements consistent with USDA\u2019s meat and poultry regulations (effective date: October 29, 2021) and develop and implement HACCP Systems (effective date: October 31, 2022). With the PR\HACCP rule, FSIS made available a guidebook for the preparation of HACCP

plans and a generic model for each food processing category defined in the regulation (9 CFR 417.2(b)(1)). The guidebook and the generic models have been revised since their initial publication to be consistent with current science and policy. FSIS recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used as is. Establishments are to tailor the model(s) to fit the establishment's operation. This generic HACCP model illustrates the Raw Non-Intact processing category with an unpasteurized liquid egg product. The model's critical control points (CCPs) do not necessarily apply to all egg products operations or products. Products or operations may require fewer or more CCPs depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. The food safety critical limits selected must come from scientific documents or other reliable sources. This model includes references for guidance on the selection of critical limits. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis are HACCP decisionmaking records (9 CFR 417.5(a)). Ensure you maintain the documents produced while developing a HACCP plan. For further assistance with developing HACCP plans, see the Egg Products Hazards and Controls Guide, the FSIS Food Safety Guideline for Egg Products, the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP Guidance webpage. Visit the State HACCP Contacts and Coordinators webpage for a list of contacts who provide technical advice, assistance, resources and conduct activities to support HACCP implementation in small and very small plants.<sup>1</sup> This information is best suited for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP model is for demonstration purposes only. The model does not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products."

"EXAMPLE PRODUCT DESCRIPTION

Product Name and Process Type: Unpasteurized Liquid Egg (Raw Non-Intact Processing Category) Process Type and Product Name Raw Non-Intact Liquid Egg Product (Whole Egg, Yolk, Whites) Important product characteristics (Aw, pH, Preservatives, etc.) None How it is to be used<sup>3</sup> Further processed into pasteurized liquid or dried egg product. Packaging (durability and storage conditions) Bulk container (e.g., tanker, totes) Storage condition and at what temperature<sup>4</sup> Perishable, not shelf stable -Keep refrigerated (\u226445\u00b0F) Where it will be sold (specify intended consumers, especially at-risk populations)<sup>5</sup> Official egg products plants for further processing. Labeling instructions and requirements \u201cDate of loading\u201d is displayed, indicating the date the container, tanker truck, or portable tank is loaded, along with product name, the statement \u201cFor Further Processing in an Official USDA Plant\u201d and the producing establishment number. What special distribution controls are required? Controls are in place to secure the product during transportation. Prior to developing the HACCP plan, please read the FSIS Guidebook for the Preparation of HACCP Plans for detailed descriptions of the worksheets and hazard analysis. The FSIS Guidebook for the Preparation of HACCP Plans and the generic HACCP models are intended

for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP models are for demonstration purposes only. The models do not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products.

3The intended use or consumer of the product must be identified in accordance with 9 CFR 417.2(a)(2). Identifying the product's intended use in the product description is one way to meet the regulatory requirements specific to 9 CFR 417.2(a)(2).

4 Each establishment's products may have their own defined shelf life. A specific shelf life may not be applicable for intermediate products.

5At-risk populations include young children, the elderly and immunocompromised persons.

6See the FSIS Labeling Overview and Generic Label Approval guideline for information on required labeling features. Not all labeling features are required for products moving between official establishments under company control.", "EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING MATERIALS

1. Hold product in cold storage unit until appropriate disposition taken (no product injurious to health will be shipped into commerce);
2. Determine and eliminate the cause of the deviation;
3. Bring the CCP under control;
4. Take measures to prevent recurrence (9 CFR 417.3).

Once per week, a supervisor will directly observe the monitoring activity, conduct the records review, and calibrate the thermometers (per manufacturer\u2019s instructions). Bulk Container Shipping Temperature Log Verification Form Corrective Action Form Pre-Shipment Form Thermometer Calibration Form DATE: APPROVED BY: 13", "i Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P). Biological hazards are living organisms. Chemical hazards may be naturally occurring in foods, used or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification.

ii Place the justification for your decision in column 4. Control measures for hazards not reasonably likely to occur are entered in column 4. Control measures for hazards reasonably likely to occur are entered in column 5. If a hazard is reasonable likely to occur, then a CCP must be addressed at this step or a later step. See FSIS Egg Products Hazards and Controls Guide for a list of frequently used controls.

iii Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced article must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS document, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan.

iv Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur (NRLTO) because the implementation of a prerequisite program (e.g., Sanitation Standard Operating Procedure (Sanitation SOP), written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation). 14"]}, {"file\_name": "FSIS\_GD\_2022\_0005", "title": "Label Application"}]

To confirm receipt or to check the status of Label Applications, contact our Distribution Team at (301)504-0883 for assistance. Questions concerning labeling regulations or policies, can be submitted through askFSIS: askFSIS or mailed to the address above for label applications. For additional assistance, contact our office at (301) 504-0878."]}, {"file\_name": "FSIS\_GD\_2022\_0006", "title": "HACCP Model for Raw Intact Farm-raised Catfish Products", "num": "FSIS-GD-2022-0006", "id": "3ed6229ecc6784ed452996e19c4e1720aa2f4aa5cd42d6e5495bdd795d40c1a", "corpus": "fsis\_guidelines", "source\_page\_url": "https://www.fsis.usda.gov/policy/fsis-guidelines", "url": "https://www.fsis.usda.gov/sites/default/files/media\_file/documents/FSIS-GD-2022-0006.pdf", "type": "pdf", "n\_pages": 14, "word\_count": 4230, "text\_by\_page": ["A Generic HACCP Model for a Raw Intact Farm-raised Catfish Product The United States Department of Agriculture (USDA) published the Pathogen Reduction/Hazard Analysis Critical Control Point (HACCP) Systems Final Rule in July 1996. The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to address safety hazards reasonably likely to occur in their production process. Therefore, this HACCP model\u2019s focus, and the focus of the other HACCP models, is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic model for each food processing category defined in regulation 9 CFR 417.2(b)(1). The guidebook and the generic models have been updated since their initial publication to be consistent with current science and policy. FSIS recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category."]}]

Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used as is. FSIS recommends that establishment tailor the model(s) to fit the establishment's operations. On December 2, 2015, FSIS published the final rule Mandatory Inspection of Fish of the Order Siluriformes and Products Derived from Such Fish (80 Federal Register 75590). The final rule amended the Agency's regulations to establish a mandatory inspection program for catfish and for products derived from catfish.<sup>1</sup> The final rule explains that, because catfish are an amenable species under the Federal Meat Inspection Act (FMIA) (21 U.S.C. 601(w)(2)), the catfish inspection program is part of the FSIS meat inspection program.<sup>2</sup> Generally, live catfish are processed into whole fish, fillets, steaks, strips, and nuggets. These products are typically sold raw. Raw products may be marinated, vacuum-tumbled, injected, or single-ingredient. Catfish fillets are also shipped frozen. Frozen products may contain a preservative (polyphosphate) which is used to minimize excessive water loss during freezing. Polyphosphates are added to the product in a (non-vacuum) tumbler. Little if any U.S. farm-raised catfish undergoes further processing into multi-ingredient ready-to-eat meals (e.g., gumbo, patties, surimi). This model illustrates the raw intact processing of farm-raised catfish into whole fish, fillets, steaks, strips, and nuggets. The model may not necessarily apply to all operations or products. Products or operations may require fewer or more Critical Control Points (CCPs) depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. For additional guidance see the FSIS Compliance Guideline for Establishments that Slaughter or Further Process Siluriformes Fish and Fish Products. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis, are HACCP decisionmaking records (9 CFR 417.5(a)). Ensure you maintain the documents produced while developing a HACCP plan.<sup>3</sup> For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage.<sup>4</sup> For purposes of convenience, the term "catfish" is used in this HACCP model. Other FSIS documents may use "fish of the order Siluriformes," "Siluriformes fish," or simply "fish" in addition to "catfish." See the Executive Summary of the final rule Mandatory Inspection of Fish of the Order Siluriformes and Products Derived From Such Fish (page 75590). Prior to developing the HACCP plan, please read the Guidebook for the Preparation of HACCP Plans for detailed descriptions of the worksheets and hazard analysis. The FSIS Guidebook for the Preparation of HACCP Plans and the generic HACCP models are intended for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP model is for demonstration purposes only. The model does not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products.

**EXAMPLE PRODUCT DESCRIPTION**

Raw Intact Catfish

Raw intact farm-raised fresh catfish (whole fish, Process or Product name fillets, steaks, strips, nuggets)

Important product characteristics

None (Aw, pH, Preservatives, etc.)

To be fully cooked prior to consumption. For further processing at this facility or another Intended use<sup>4</sup> establishment or intended for cooking by end consumer

Packaging (durability and storage Vacuum-packaged, tray packs or bulk pack conditions) boxes

with liners. Refrigerated -5 days when held at 40°F. Shelf life and at what temperature5  
Frozen -4 months when held at 0°F. Where it will be sold (specify Sold to household  
consumers through retail intended consumers, especially at outlets or distributed to hotels,  
restaurants, and risk populations)6 institutions (HRI). Product name, inspection legend and  
establishment number, handling statement, safe Labeling instructions and handling  
instructions, net weight statement, requirements address line, nutrition facts panel, and  
ingredients list.7 Special distribution control None DATE: APPROVED

BY: \_\_\_\_\_ 4The intended use or consumer of the product must be  
identified in accordance with 9 CFR417.2(a)(2). Identifying the product's intended use in  
the product description is one way to meet the regulatory requirements specific to 417.2(a)(2).  
5Each establishment's products may have their own defined shelf life. 6At-risk  
populations include young children, the elderly, and immunocompromised persons. 7See the  
Labeling and Label Approval webpage for information on required labeling features and other  
labeling resources. Page 2 of 14", "EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING  
MATERIAL8 Raw Intact Catfish Meat Live farm-raised catfish Non-meat food ingredients  
Polyphosphate mixture Antimicrobial interventions9 and None processing aids Packaging  
material Plastic wrap and trays Restricted ingredients or Allergens Catfish contains allergenic  
proteins Other None DATE: APPROVED BY: \_\_\_\_\_ 8List all meat, non-  
meat ingredients, restricted ingredients (for example, nitrites), processing aids, and packaging  
material used in production of this product. This is important to help identify any special  
ingredients or processes to address in the HACCP plan. See the FSIS Compliance Guideline  
Allergens and Ingredients of Public Health Concern: Identification, Prevention and Control, and  
Declaration through Labeling for detailed information on allergens. 9FSIS and the Food and Drug  
Administration (FDA) have a memorandum of understanding (MOU) that establishes the working  
relationship followed when responding to notifications for the use of food additives (including  
ingredients) intended for use in the production of FSIS regulated products. FSIS determines the  
suitability of the use of food ingredients used in the production of meat, poultry, and egg  
products. FSIS consults, as necessary, with FDA on the requirements under the Federal Food,  
Drug & Cosmetic Act (FD&C Act) and its implementing regulations. See FSIS Directive  
7120.1, Safe and Suitable Ingredients Used in Meat Poultry and Egg Products for the list of  
suitable ingredients. Page 3 of 14", "b 11 2022 b ~ ~ EXAMPLE PROCESS FLOW

flow diagram. Establishments' flow diagrams for the same product may be different.  
Establishments determine which steps are included in their process. The steps must represent  
all relevant hazards in the hazard analysis. 11 Step 7 represents the manual  
processing procedures used to produce fillets, steaks, strips, and nuggets. 12 The Returned  
Product step (18) is shown not connected to another step. Returned product may re-enter the  
production system at different process steps depending on condition or food safety concerns.

Returned product may be relabeled, repackaged, or discarded. Page 4 of 14", "EXAMPLE HAZARD ANALYSIS Raw Intact Catfish Potential Hazard13 Is the Hazard Reasonably Likely to occur (RLTO)? Justification or Basis for Decision14 If yes in Column 2 (hazard RLTO), What Control Measures Can Be Applied to Prevent, Eliminate, or Reduce the Hazard to Acceptable Levels15 Is this Step a Critical Control Point (CCP)? 1. Receiving Farm-raised Catfish B: Salmonella No A hazard identification study identified Salmonella as one of the few potential hazards. There is evidence that at least one outbreak of human salmonellosis may have been related to catfish consumption. Although Salmonella has been isolated from farm-raised catfish fillets, Salmonella contamination is a hazard not reasonably likely to occur when processing catfish. Product is to be fully cooked prior to consumption. 13Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P). Biological hazards are living organisms. Chemical hazards may be naturally occurring in foods, used or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification. 14Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced articles must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS program, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan. 15Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, or antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5). The HACCP regulations (9 CFR Part 417) require establishments to develop and implement a system of controls designed to address safety hazards reasonably likely to occur in their production process. Therefore, this HACCP model\u2019s focus, and the focus of the other HACCP models, is on product safety, not product quality characteristics. With the rule, FSIS made available a guidebook for the preparation of HACCP plans and a generic model for each food processing category defined in regulation 9 CFR 417.2(b)(1). The guidebook and the generic models have been updated since their initial publication to be consistent with current science and policy. FSIS"]}

recommends you use the updated Guidebook for the Preparation of HACCP Plans when developing an establishment-specific HACCP plan. Generic models serve as useful examples of how to meet the regulatory requirements. Each model represents a food processing category. Each processing category may contain numerous products. Therefore, each single model represents a category of products and, as such, the models do not demonstrate unique products or novel processes. The generic models are not intended to be used as is. FSIS recommends that establishment tailor the model(s) to fit the establishment's operations. On December 2, 2015, FSIS published the final rule Mandatory Inspection of Fish of the Order Siluriformes and Products Derived from Such Fish (80 Federal Register 75590). The final rule amended the Agency's regulations to establish a mandatory inspection program for catfish and for products derived from catfish.<sup>1</sup> The final rule explains that, because catfish are an amenable species under the Federal Meat Inspection Act (FMIA) (21 U.S.C. 601(w)(2)), the catfish inspection program is part of the FSIS meat inspection program.<sup>2</sup> Generally, live catfish are processed into whole fish, fillets, steaks, strips, and nuggets. These products are typically sold raw. Raw products may be marinated, vacuum-tumbled, injected, or single-ingredient. This model illustrates the raw intact processing of wild-caught catfish into whole fish, fillets, steaks, strips, and nuggets. The model may not necessarily apply to all operations or products.

Products or operations may require fewer or more Critical Control Points (CCPs) depending on the operation. The flow diagram demonstrates a general production process and should be modified to reflect the processes used at the establishment. For additional guidance see the FSIS Compliance Guideline for Establishments that Slaughter or Further Process Siluriformes Fish and Fish Products. The records produced while documenting a HACCP plan, including all documentation used to support the hazard analysis, are HACCP decisionmaking records (9 CFR 417.5(a)). Ensure you maintain the documents produced while developing a HACCP plan.<sup>3</sup> For further assistance with developing HACCP plans see the Guidebook for the Preparation of HACCP Plans and the guidance materials available on the FSIS HACCP webpage. <sup>4</sup> For purposes of convenience, the term "catfish" is used in this HACCP model. Other FSIS documents may use "fish of the order Siluriformes" or simply "fish" in addition to "catfish". <sup>5</sup> See the Executive Summary of the final rule Mandatory Inspection of Fish of the Order Siluriformes and Products Derived From Such Fish (page 75590). <sup>6</sup> Prior to developing the HACCP plan, please read the Guidebook for the Preparation of HACCP Plans for detailed descriptions of the worksheets and hazard analysis. The FSIS Guidebook for the Preparation of HACCP Plans and the generic HACCP models are intended for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP model is for demonstration purposes only. The model does not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. <sup>7</sup> Page 1 of 13, "EXAMPLE PRODUCT DESCRIPTION" Raw Intact Catfish Process or Product name Important product characteristics (Aw, pH, Preservatives, etc.) Intended use<sup>8</sup> Packaging (durability and storage conditions) Shelf life and at what temperature<sup>9</sup> Where it will be sold (specify intended consumers, especially at-risk populations)<sup>10</sup> Labeling instructions and requirements Special distribution control DATE: Raw intact wild-caught fresh catfish (whole fish, fillets, steaks, strips, nuggets) None To be fully cooked prior to consumption. The FSIS Guidebook for the Preparation of HACCP Plans and the generic HACCP models are intended for small and very small establishments seeking assistance in understanding the requirements in Title 9 Code of Federal Regulations (9 CFR) Part 417. The HACCP models are for demonstration purposes only. The models do not represent requirements that must be met. Establishments are required to develop HACCP plans specific to their facilities, production practices, and products. 5 The intended use or consumer of the product must be identified in accordance with 9 CFR 417.2(a)(2). Identifying the product's intended use in the product description is one way to meet the regulatory requirements specific to 417.2(a)(2). 6 Each establishment's products may have their own defined shelf life. 7 At-risk populations include young children, the elderly, and immunocompromised persons. 8 See the Labeling and Label Approval webpage for information on required labeling features and other labeling resources. Page 2 of 13, "EXAMPLE LIST OF PRODUCT INGREDIENTS AND INCOMING MATERIAL" 9 Raw Intact Catfish Meat Live wild-caught catfish Non-meat food ingredients None Antimicrobial interventions 10 and None processing aids Packaging material Plastic wrap and trays, boxes and liners Restricted ingredients or Allergens Catfish contains allergenic proteins Other None DATE: APPROVED BY: \_\_\_\_\_ 9 List all meat, non-meat ingredients, restricted ingredients (for example, nitrites), processing aids, and packaging material used in production of this product. This is important to help identify any special ingredients or processes to address in the HACCP plan. See the FSIS Compliance Guideline Allergens and Ingredients of Public Health Concern: Identification, Prevention and Control, and Declaration through Labeling for detailed information on allergens. 10 FSIS and the Food and Drug Administration (FDA) have a memorandum of understanding (MOU) that establishes the working relationship followed when responding to notifications for the use of food additives (including ingredients) intended for use in the production of FSIS regulated products. FSIS determines the suitability of the use of food ingredients used in the production of meat, poultry, and egg products. FSIS consults, as necessary, with FDA on the requirements under the Federal Food, Drug & Cosmetic Act (FD&C Act) and its implementing regulations. See FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat Poultry and Egg Products for the list of suitable ingredients. .1 ----- EXAMPLE HAZARD ANALYSIS

Raw Intact Catfish Potential Hazard<sup>14</sup> Is the Hazard Reasonably Likely to occur (RLTO)?

Justification or Basis for Decision<sup>15</sup> If yes in Column 2 (hazard RLTO), What Control Measures Can Be Applied to Prevent, Eliminate, or Reduce the Hazard to Acceptable Levels<sup>16</sup> Is this Step a Critical Control Point (CCP)? 1. Receiving Wild-caught Catfish CCP 1 B: Salmonella No A hazard identification study identified Salmonella as one of the few potential hazards.<sup>17</sup> There is evidence that at least one outbreak of human salmonellosis may have been related to catfish consumption. Although Salmonella has been isolated from wild-caught catfish product, Salmonella is considered not reasonably likely to occur when processing wild-caught catfish.<sup>18</sup>

<sup>14</sup>Hazards are grouped into three categories: Biological (B), Chemical (C), and Physical (P).

Biological hazards are living organisms. Chemical hazards may be naturally occurring in foods, used or added during the processing of foods, or administered to live animals. Physical hazards are a component of a food that is unexpected, such as plastic, glass, metal, or bone in a boneless product. See the Guidebook for the Preparation of HACCP Plans for more information about hazards identification. <sup>15</sup>Scientific references are important in making decisions, providing justifications, and validating the HACCP system. When scientific references are used for decisions, the referenced articles must be part of the HACCP records. If the scientific justification is from FSIS, then list the document name. If justification is not from an FSIS program, then HACCP system design must be supported by documentary evidence \u2013 that is, the theoretical principles, expert advice from processing authorities, scientific or technical data, peer-reviewed journal articles, pathogen modeling programs, or other information demonstrating that particular process control measures can adequately prevent, reduce, or eliminate specific hazards. These non-FSIS supporting documents must be kept for the life of the HACCP plan. <sup>16</sup>Because the results obtained under prerequisite programs could affect decisions made in the hazard analysis, an establishment is required to maintain records associated with these programs as supporting documentation for its hazard analysis (9 CFR 417.5(a)). When an establishment determines that a potential hazard is not reasonably likely to occur because the implementation of a prerequisite program (e.g., Sanitation SOP, written sanitary dressing procedures incorporated into prerequisite programs, purchase specifications, or antimicrobial interventions) prevents conditions that make the potential hazard likely, that prerequisite program then becomes part of the HACCP system and as a result, must be validated. This means that establishments must maintain scientific or technical support for the design of those prerequisite programs used to support decisions in the hazard analysis and must collect in-plant validation data to support that the programs are implemented as designed (see FSIS Compliance Guideline HACCP Systems Validation, page 5). <sup>17</sup>See the Assessment of the Potential Change in Human Health Risk associated with Applying Inspection to Fish of the order Siluriformes. <sup>18</sup>Abstract: Effect of Federal Inspection on Louisiana Wild-Caught Catfish Industry, Prevalence of Salmonella, and Microbial Characteristics of Raw Wild-Caught Catfish Fillets Page 5 of 13", "\u00b7-----;-----1-----

-----\u00b7----- '----- '\u2022----- a----- Potential Hazard  
RLTO Justification or Basis Controls CCP 4. Whole Dressed Fish B: Salmonella No Outgrowth C: Sanitizers No P: Foreign No Materials Written Sanitation SOPs to prevent or minimize cross-contamination. Temperature Control SOP for the processing area to aid in the control of Salmonella outgrowth. The total time required to remove heads, eviscerate, and prepare products for packaging is short enough to preclude the outgrowth of Salmonella and meets the time and temperature parameters in the FDA guidance.<sup>26</sup> Written Chemical Receiving, Storage, and Use SOP for mixing and determining concentration of chemicals to ensure the mixture is made per the manufacturer's instructions and is within the allowable limits identified in Directive 7120.1 (FCN# [insert number]).<sup>27</sup> Written Foreign Material SOP requires daily equipment examination and preventive maintenance to prevent foreign materials (e.g., metal, rubber, plastic) from contaminating the product.<sup>28</sup> No historical findings of foreign material contamination.<sup>29</sup> See the Federal Food and Drug Administration's Fish and Fishery Products Hazards and Controls Guidance (Table A-2 page 421). Provide reference for scientific support and validation for effective concentrations and support for critical operational parameters that reduce biological hazards. FSIS Directive 7120.1, Safe and Suitable Ingredients Used in Meat, Poultry and Egg Products contains the list of substances that may be used in the production of meat and poultry products. The list contains the allowable amounts and the intended use of the approved antimicrobials. The list (Directive 7120.1) can be used as supporting documentation for chemical hazard controls (safety and suitability). Directive 7120.1 cannot be used as support for the control of biological hazards because the antimicrobial

concentration needed to control bacteria is different from the concentrations required for safety and suitability. 28This Foreign Material SOP(prerequisite program) should have details on how this procedure(such as metal prevention controls)is preventing the hazard from occurring as well as the on-going verification procedures. These controls should be evident within the written document upon review. The Foreign Material SOP and plant data related to on-going verification activities then become part of recordkeeping and historical data. 29Note:this \u201chistorical data\u201d must be supported with evidence from the establishment through the establishment\u2019s history or validation data with reference to the actual SOP or prerequisite program. When historical data is not available (for example,a HACCP plan for a new process or product), then system design must be supported by other documentary evidence. Such as the Fish and Fishery Products Hazards and Controls Guidance which states \u201cpreventive measures for metal inclusion can include periodically checking equipment for damaged or missing parts\u201d (page 386). Page 8 of 13","-----r-----\"T\"-----

temperature during processing is not to exceed the time and temperature parameters in the  
FDA\u2019s Fish and Fishery Products Hazards and Control Guidance (Table A-2,page 421).31  
Written Processing SOP for maintenance of ice and water solution 30 Establishments may be  
able to safely process catfish without an ice and water chilling process, relying instead on the  
coolers and freezers to bring down product temperatures. 31 If an establishment implements a  
process consistent with the process specifications described in the scientific support, and the  
scientific support contains microbiological data specifying the level of pathogen reduction  
achieved by the intervention strategy for the target pathogen identified in the hazard analysis,  
the in-plant data collected during the 90 day initial validation period will consist of data on  
quantifiable characteristics of the critical operational parameters, such as pressure,  
temperature, and concentration. However, if an establishment implements different critical  
operational parameters in the process from the scientific support, or the scientific support  
identified does not contain microbiological data, then the establishment should collect in-plant  
data demonstrating the critical operational parameters that it has implemented can all be met  
AND should collect in-plant microbiological data or identify scientific support with  
microbiological data that demonstrates the effectiveness of those implemented critical  
operational parameter (FSIS Compliance Guideline HACCP Systems Validation, page 27). Page 9

Preface This is a revised version of the FSIS Guideline for Label Approval. It replaces the July 2020 version of the guideline. The previous version of the guideline was titled the \u201cFSIS Compliance Guideline for Label Approval.\u201d The Food Safety and Inspection Service (FSIS) has renamed the guideline the \u201cFSIS Guideline for Label Approval,\u201d so asnotto give the impression thatthe documenthasforce and effectof law. This guideline represents FSIS\u2019 current thinking on these topics and should be considered effectiveas ofits issuance. Establishments that used previous versions of the FSIS Guideline for Label Approval should update their procedures as necessary based on this guideline. For purposes of this document, the term \u201cestablishment(s)\u201d includes official meat and poultry establishments and egg products plants, unless otherwise indicated. The information in this guideline is provided to assist establishments in meeting regulatory requirements. The contents of this document do not have the force and effect of law and are not meant to bind the public in any way. This document is intended only to provide clarity to industry regarding existing requirements under the regulations. This guideline is focused on small and very small establishments, in support of the Small Business Administration\u2019s initiative to provide small businesses with compliance assistance under the Small Business Regulatory Fairness Act. However, all establishments may apply the recommendations in this guideline. It is important that small and very small establishments have access to a full range of scientific and technical support, and the assistance needed to label products in compliance with FSIS regulations. Although large establishments can benefit from the information provided, focusing the guideline on the needs of small and very small establishments provides them with assistance that may be otherwise unavailable to them. Congressional Review Act Pursuant to the Congressional Review Act at 5 U.S.C. 801 et seq, the Office of Information and Regulatory Affairs .....	35

has determined that this guideline is not a major rule, as defined by 5 U.S.C. 804(2). Key Point Purpose LPDS only needs to evaluate three types of labels prior to use in commerce (9 CFR 412.1 (c)): This guideline provides information about 1) Labels for religious exempt products 9 CFR the types of labels that must be submitted 412.1 (c) (1). 2) Labels with special statements and claims to LPDS for approval. Specifically, LPDS 9 CFR 412.1 (c) (3). must review three categories of labels 3) Labels for temporary approval 9 CFR 412.1 before they may be used in commerce: (c) (4). labels for religious exempt products (9 CFR 412.1(c)(1)), labels with special statements and claims (9 CFR 412.1(c)(3)), and labels for temporary approval 9 CFR 412.1(c)(4). All other categories of labels are considered generically approved, meaning they may be used in commerce without prior review by LPDS provided that they meet all applicable labeling requirements. All labels, including 3", "generically approved labels, are, subject to routine verification by FSIS field inspectors to ensure ongoing compliance with FSIS labeling requirements. All labels, whether submitted to LPDS for approval or generically approved, are required to comply with all FSIS labeling requirements. To assist establishments with the design and modification of their product labels, this guideline includes specific examples of special statements and claims that must be submitted to LPDS for approval. This guideline also provides examples of: (1) factual statements and claims that are eligible for generic approval, (2) changes that can be made to labels approved with special statements and claims without additional LPDS review, (3) changes that cannot be made to labels approved with special statements and claims without additional LPDS review, (4) blanket label approvals (labels for product line or multiple product lines with identical claims), (5) information about negative claims, (6) information about export labels with deviations from domestic requirements, and ( geographic landmark claims on labels and additional information about label approval. Reason for Reissuing the Guideline FSIS reissued this guideline in response to comments received on the previous version and to improve clarity. This revision also reflects changes to generic labelling approval eligibility established by the final rule, Prior Label Approval System: Expansion of Generic Label Approval (88 FR 2798). The final rule expanded generic approval to products only intended for export that deviate from domestic labeling requirements and permitted generic approval of the labels of products that receive voluntary FSIS inspection. It also expanded generic approval to: (1) organic claims that appear in a product label\u2019s ingredients statement; (2) geographic landmarks\u201d displayed on a product label; (3) negative\u201d claims made on product labels that identify the absence of certain ingredients or types of ingredients. In addition, the final rule announced that LPDS will no longer evaluate generically approved labels voluntarily submitted to LPDS for review. Changes from the Previous Version of the Guideline This guideline, dated January 2023, is final. FSIS will update this guideline, as necessary, should new information become available. This version incorporates the following changes: The guideline\u2019s title was shortened from the FSIS Compliance Guideline for Label Approval to the FSIS Guideline for Label Approval. In the appendices, A bold red asterisk (\*) marks new or updated entries to the appendix. Items previously on the list not marked by a bold red asterisk (\*) may have been rearranged for ease of readability. A bold plus (+) marks claims that reference a guideline that is hyperlinked at the end of the appendix. A red bold hash (#) marks reference that there is additional information about this factual negative statement in Appendix 7. Appendix 1 now includes new

examples of special statements and claims that require LPDS approval before they can be used on labels of product in commerce 4", "(e.g., \u201cnatural\u201d and \u201cno animal by-products\u201d claims). Some other types of claims were moved from Appendix 1 to Appendix 2, given they are now eligible for generic approval (e.g., certain negative claims and state endorsement programs that have geographic emblematic design). \u2022 Appendix 2 now includes several new factual statements and claims that do not require LPDS approval before they can be used on labels of product in commerce (e.g., \u201cAuthentic,\u201d and \u201cDouble Smoked\u201d). \u2022 Appendix 3 no longer references export labels that deviate from domestic requirements, as those labels are no longer required to be submitted to LPDS for approval. \u2022 Appendix 4 no longer includes two examples of export labels, given they are now eligible for generic label approval. \u2022 Appendix 5 includes new examples of labels that can be approved as a blanket approval. \u2022 Appendix 6 includes new examples of special statements and claims that can be generically approved after receiving the first approval from LPDS. \u2022 Appendix 7 has been added to provide information and examples about the types of negative claims that are generically approved. \u2022 Appendix 8 has been added to provide information about the generic approval of export labels that deviate from domestic requirements and geographic landmark claims. \u2022 Appendix 9 is now entitled \u201cAdditional Information for Label Approval,\u201d which was the previous title of Appendix 7.

**How to Effectively Use the Guideline**

This guideline is organized to provide users with FSIS\u2019s current thinking on its labeling regulations. To use this guideline, LPDS recommends that readers use the navigation headings to move efficiently through the document sections of interest. Hyperlinks, where provided, will quickly take you to the correct place in the document electronically and are also provided for other complementary documents. The Resources section of this guideline provides resource material used in the revision of this guidance.

**How to Comment on the Guideline**

FSIS is seeking public comment on this guideline as part of its efforts to continuously assess and improve the effectiveness of policy documents. All interested persons may submit comments regarding any aspect of this document, including but not limited to content, readability, applicability, and accessibility. The comment period will be 60 days from publication of the Federal Register Notice (88 FR 2798) and, as appropriate, the 5", "Agency may update this guideline in response to comments.

Although FSIS may make changes to future iterations of this guideline in response to comments, this document reflects current thinking. FSIS encourages establishments producing products discussed in this document to review it. Comments may be submitted by either of the following methods:

- \u2022 Federal eRulemaking Portal Online submission at [Regulations.gov](https://www.regulations.gov). This website provides a way to type short comments directly into the comment field on the webpage or attach a file to submit lengthier comments. Follow the online instructions at that site to submit comments.
- \u2022 Mail and hand- or courier-delivered items: Send to Docket Clerk, U.S. Department of Agriculture (USDA), FSIS, 1400 Independence Avenue SW, Washington, D.C. 20250-3700. All items submitted by mail or electronic mail must include the Agency name, FSIS, and document title: FSIS GUIDELINE FOR LABEL APPROVAL. Comments received will be made available for public inspection and posted without change, including any personal information, on <https://www.regulations.gov>.

**Questions Regarding Topics in this Guideline**

If after reading this guideline you still have questions, FSIS recommends searching the publicly posted Knowledge Articles (\u201cPublic Q&As\u201d) in the askFSIS database. If after

searching the database, you still have questions, refer them to the Office of Policy and Program Development through askFSIS and select Labeling as the Inquiry type or by telephone at 1-800-233-3935. Documenting these questions helps FSIS improve and refine present and future versions of the guideline and associated issuances.

6", "FSIS Guideline for Label Approval Background FSIS is publishing this guideline to provide information about the types of labels that must be submitted to the Agency for approval, including specific examples of special statements and claims. To prevent the introduction of adulterated or misbranded products into commerce, LPDS implements a prior label approval system for labels intended to be used on federally inspected meat, poultry, and egg products, including imported products (9 CFR 412). Without approved labels, meat, poultry, and egg products may not be sold, offered for sale, or otherwise distributed in commerce. Under LPDS\u2019 prior label approval system, there are two types of label approval. First, certain categories of labels must receive \u201ckscketch approval\u201d (9 CFR 412.1). To receive sketch approval, establishments must submit a rendering of their label (i.e., a \u201ckscketch label) to LPDS for evaluation prior to use in commerce. The sketch label must reasonably represent what the label will ultimately look like but need not be the actual final label applied to the product. Other categories of labels are \u201cgenerically approved,\u201d meaning they are approved for use in commerce without LPDS evaluation so long as they are consistent with FSIS regulations (9 CFR 412.2).

Establishments do not need to submit generically approved labels to LPDS for evaluation prior to use so long as they meet all applicable labeling requirements. However, all labels, including generically approved labels are subject to routine verification by FSIS field inspectors. The categories of labels that require sketch approval and, therefore, need to be submitted to LPDS for evaluation are: 1) Labels for religious exempt products 9 CFR 412.1(c) (1); 2) Labels with special statements and claims 9 CFR 412.1 (c) (3); and 3) Labels for temporary approval 9 CFR 412.1(c) (4). Below, there is further discussion about special statements and claims that require submission to LPDS for approval and additional information about generic approval, including:

\u2022 Special statements and claims that require submission to LPDS;

\u2022 Factual statements and claims that are generically approved;

\u2022 Changes that can be made to labels approved with special statements and claims without additional LPDS review;

\u2022 Changes that cannot be made to labels approved with special statements and claims without additional LPDS review;

7", "\u2022 Blanket label approvals (labels for product line or multiple product lines with identical claims);

\u2022 Special statements and claims that can be generically approved after first approval by LPDS;

\u2022 Information about negative claims;

\u2022 Information about export labels with deviations from domestic requirements and geographic landmark claims on labels and;

\u2022 Additional information about label approval.

More information can also be found in each of the appendices summarized below.

Special Statements and Claims (9 CFR 412.1 (c) (3))

\u201cSpecial statements and claims\u201d are claims, logos, trademarks, and other symbols on labels that are generally not defined in FSIS regulations or in the Food Standards and Labeling Policy Book.

\u2022 An example of a logo or symbol is a graphic representation of a heart.

Special statements and claims include

\u201cnatural\u201d claims, \u201ccertified gluten free\u201d claims (e.g., Certified Gluten Free by XYZ entity), health claims, ingredient and processing method claims (e.g., high-pressure processing), claims regarding the raising of animals, organic claims, and instructional or disclaimer statements concerning pathogens (e.g., \u201cfor cooking only\u201d or \u201cnot

tested for E-coli O157:H7\u201d). See Appendix 1 for an expanded list of examples of special statements and claims. Factual Statements and Claims Generically Approved (9 CFR 412.2) FSIS does not consider some factual statements applied to labels to be special statements or claims that require submission to LPDS for approval. Rather, they are statements offactthat mustbe supported in the labeling record.These factual statements are generically approved. \u2022 Examples of factual statements in this category include defined geographic styles (e.g., \u201cItalian Style\u201d), \u201cextra\u201d or \u201cmore\u201d statements (e.g., \u201c10% more cheese\u201d), geographic landmarks (e.g., Statue of Liberty, maps, flags), organic ingredients listed in the ingredients statement (e.g., organic sugar or organic garlic), and allergen statements (e.g., \u201ccontains milk\u201d) consistent with the Food Allergen Labeling and Consumer Protection Act. Most negative claims (e.g., \u201cNo Pork\u201d) are also generically approved, including \u201cgluten free\u201d (without an accompanying certification statement) and \u201cno monosodium glutamate (MSG)\u201d or \u201cno MSG added\u201d with appropriate disclaimer statement. However, LPDS evaluation continues to be required for labels that bear negative claims relating to the raising of the animal from which the product is derived (e.g., \u201cno antibiotics administered\u201d) or negative claims relating to the use of genetically modified ingredients. For more information about animal raising claims, see the Labeling Guideline on Documentation Needed to Substantiate Animal Raising Claims for Label Submissions (2019). For more information about negative claims related to the use of genetically modified ingredients, see the Labeling Guideline on 8", "Statements that Bioengineered or Genetically-Modified Ingredients or Animal Feed were not used in Meat, Poultry or Egg Products. See Appendix 2 for an expanded list of examples of factual statements that are generically approved. Changes to Labels with Approved Special Statements and Claims That Do Not Require Additional LPDS Review Once a label is approved by LPDS for compliance with 9 CFR 412.1, there are several changes that can be made to the label that do not require resubmission to LPDS. These changes are generically approved under 9 CFR 412.2. For such a change to be made, it must be unrelated to the special statement or claim. Some common examples include: \u2022 The removal of an ingredient or change in order of predominance of an ingredient in a product formula for a label that was previously approved with a negative claim (e.g., \u201ccertified gluten free\u201d). In this case, the removal of an ingredient or change in its order of predominance will not affectthe special statement or claim. \u2022 Changing the name of the cut of meat or poultry for a label previously approved with an animal-raising claim (e.g., raised without antibiotics). An example would include changing the name from chicken breast to chicken thigh. The change is generically approved provided the supporting documentation for the chicken is the same as documented in the previously approved label. In this case, changing the name ofthe cutofpoultry willnotaffectthe special statement or claim. \u2022 Changing information such as the establishment number (except for products labeled as organic), signature line, preparation instructions, Hazard Analysis and Critical Control Points Category, or vignette for a label that was previously approved with a special statement or claim. These changes are generically approved as they will not affectthe special statement or claim. See Appendix 3 for a list of changes to labels with special statements and claims that can be generically approved. Changes to Labels with Approved Special Statements and Claims that Require Additional LPDS Review Sometimes, changes made to a previously approved label with special statements and claims

require LPDS approval before the updated label may be used in commerce. Such changes include those that affect the special statement or claim and require LPDS to reevaluate the product formula or other relevant information. Examples include: \u2022 A label with a negative claim (e.g., \u201ccertified gluten free\u201d) that was previously approved by LPDS. Now, the establishment wants to update its label to reflect the use of a new seasoning mix, which includes ingredients that were not in the product formula for the previously approved label. In this case, the establishment is required to resubmit the label to LPDS for approval, so the Agency can verify that the new ingredients do not contain any sources of gluten. \u2022 If a company adds an uncured claim to a previously approved label with a \u201cnatural\u201d and \u201ccertified gluten free\u201d claim, the company must resubmit the label to LPDS for approval because it contains a new special statement or claim not included as part of the previous approval. See Appendix 4 for a list of examples of changes to labels with special statements and claims that need to be resubmitted to LPDS. Blanket Label Approvals (Labels for product line or multiple products with identical claims) In some cases, the addition of a special statement or claim to an entire line of products or multiple products will not require every single label to be submitted to LPDS for approval. Instead, establishments may submit a \u201cblanket approval\u201d application to LPDS along with a label for one of the products. The establishment should also include supporting documentation with its application indicating that the establishment is requesting approval for the use of the special statement or claim on multiple product labels. The label application should indicate that the special statement or claim will be added to an entire product line and should specify the product line, or, in the case of only certain labels, the application should list the product labels to which the approval would apply. Some examples include: \u2022 An establishment produces 50 different frozen meals. The establishment intends to add a Front of Pack (FOP) statement for all 50 products that will identify the number of calories and grams of protein. In this case, the establishment should not submit 50 applications for different products in a product line for approval. Instead, the establishment should submit an application for blanket approval to LPDS, along with a label for one of the products. The label application should indicate that the FOP statement will be added to all frozen product meals produced at the establishment. The blanket approval will cover products to which the FOP statement is applied so there is no need for each individual label bearing the FOP information to be submitted for approval. The establishment should update the individual nutrient values within the FOP statement generically to match the nutrient values displayed in the nutrition facts panel for each of the meals. However, when a new nutrient is added to the FOP statement, the label can no longer be generically approved (e.g., adding sodium to the statement that already displays the calories and grams of protein). Adding a new nutrient to the FOP statement will require the revised label to be resubmitted to LPDS for evaluation and approval. \u2022 An establishment produces X number of organic chicken parts. To obtain approval to label all organic chicken parts with a new claim, such as \u201cno antibiotics,\u201d the establishment should submit one organic chicken breast package with the new \u201cno antibiotic\u201d claim to LPDS. The label application should also include a list of other chicken parts that will also use the new claim. This is a blanket approval because all the parts of the chicken listed in the application will be approved through one label submission. \u2022 An establishment has an entire line of beef sausages that LPDS approved with a \u201ccertified gluten free\u201d claim. The establishment wants to add a \u201cmade with

grass fed beef\u201d claim to all the other product labels in the beef sausage product line. Instead of submitting separate applications for each of the individual products, the establishment should submit a request for blanket approval with the 10", "necessary supporting documentation for the \u201cmade with grass-fed beef\u201d claim and a list of all the products in the line. The addition of a \u201cmade with grass-fed beef\u201d claim does not affect the previously approved \u201ccertified gluten free\u201d claim because there is no change to the ingredients. The addition of the \u201cmade with grass-fed beef\u201d claim for products formulated with grass fed beef is a type of claim that can be approved through a request for blanket approval. See Appendix 5 for additional types of special statements and claims that can be approved through a blanket approval. Special Statements and Claims Generically Approved After the First Approval from LPDS There are certain types of special statements and claims that LPDS only needs to see once to ensure compliance with the regulations. After this initial review, the special statements and claims are generically approved for use on any other product produced by the establishment on the condition that future labels using the special statements and claims follow all FSIS requirements and that the special statements and claims are not changed in any way from the initial LPDS approval. Some examples include: \u2022 A label that displays a USDA Food Shield was approved for a Chicken Cordon Bleu product. The establishment wants to add the shield to a Chicken Parmesan product as well. Because the establishment has the prior approval from LPDS for the USDA Food shield and has the supporting documentation from the USDA Agricultural Marketing Service (AMS) on file, the Chicken Parmesan label can be generically approved. This label can be generically approved because the shield was previously approved by LPDS and the label application has the documentation from AMS to support the use of the claim on the label. \u2022 A label for chicken hot dogs was approved with a \u201ccertified halal\u201d claim. The establishment now wants to make a certified halal chicken sausage. The establishment has the prior approval from LPDS for the certified halal claim and the supporting documentation from the certified Halal organization. This label can be generically approved because the establishment has the certification from the Halal organization that supports the use of the claim on the label. The establishment would need to ensure that the documentation is kept current per FSIS requirements. See Appendix 6 for additional examples. Negative Claims The \u201cnegative\u201d claims section provides label examples of ingredient-based claims (e.g., \u201cgluten free without the accompanying certification statement,\u201d \u201cNo MSG\u201d/No MSG Added [with the accompanying disclaimer statement],\u201d and \u201cno preservatives\u201d that can be generically approved. \u201cNegative\u201d claims are claims made on product labels that identify the absence of certain ingredients or types of ingredients and are generically approved. Negative claims labeling is allowed to indicate the absence of an ingredient when that ingredient is expected or permitted by regulation or policy. This could also apply to ingredients which are not expected or permitted by regulation or policy if the 11", "ingredients could find their way into the product through a component. For example, the use of \u201cno preservatives\u201d on the label of \u201cspaghetti with meat and sauce\u201d (where regulations do not permit the direct addition of preservatives) would be acceptable if the product contained an ingredient, such as cooking oil, which could contain preservatives but do not. The claims are truthful and not misleading because the ingredients statement provides support that the product does not contain the ingredient. Also in this

section are definitions of certain claims such as \u201cNo Artificial Flavors,\u201d \u201cNo Artificial Colors,\u201d \u201cNo Artificial Colors and Flavors,\u201d and \u201cNo Artificial Preservatives.\u201d There are sample labels to provide further explanation as to what is allowed on the label with these claims. Labels with negative claims that have animal-raising claims and/or nongenetically modified organisms (non-GMO) claims are not eligible for generic approval. An example of a negative claim that can be generically approved includes: \u2022 A label with a gluten free claim. Gluten free highlights the absence of gluten containing ingredients. A claim such as gluten free can be verified by examining the ingredients statement for any gluten-containing ingredients. If the product does contain any gluten containing ingredients, the claim would not be permitted on the label. See Appendix 7 for additional types of negative claims and label examples that can be generically approved. Export Labels that Deviate from Domestic Requirements and Geographic Landmark Claims on Labels The export labels with deviations from domestic requirements section provides information about the documentation and support needed for labels on products that are exported outside of the United States and have deviations from domestic requirements. Such labels must meet the requirements of the importing country, as indicated in the FSIS Export Library. An example of an export label that can be generically approved includes: \u2022 A label for Abratwurst that has a nutrition facts panel that deviates from United States domestic requirements and the ingredients statement contains incomplete sublists of the ingredients. The label would be acceptable to generically approve as the label complies with the foreign country's labeling requirements. Documentation supporting the acceptability of the deviation should be kept in the establishment's labeling records to comply with 9 CFR 320.1(b)(10) and 381.175(b)(6). FSIS inspection program personnel (IPP) verify whether product for export meets requirements listed in the Export Library, including labeling, when certifying products for export. In addition to the information from the Export Library, additional documentation, such as a letter from the importer of record on letterhead, can be used to support that the label is in compliance with importing countries labeling requirements for verification purposes. The geographic landmark claim on labels section provides information about labels that comply with 9 CFR 317.8 (b) (1) or 9 CFR 381.129 (b) (2), the state endorsement programs that have a geographic emblematic design, state endorsement programs that do not have a geographic emblematic design, and geographic style documentation by 12", "third-party authority claims on labels. There is also a list of the geographic claims on labels that are found in the Food Standards and Labeling Policy Book. An example of a geographic landmark claim that can be generically approved includes: \u2022 A label with a Go Texan with a map of Texas on the label can be generically approved and there needs to be support in the labeling record that the product complies with the Go Texan requirements. The support can be a certificate for being a member of the Go Texan program or a letter from the certifying entity stating the label is compliant with their requirements. The documentation should be updated once a year to remain compliant. See Appendix 8 for additional information about export labels that deviate from domestic requirements and geographic landmark claims that can be generically approved. Additional Information for Label Approval Appendix 9 provides general information about label approval and information about the other categories of labels (i.e., labels for temporary approval, including label transfers, and labels for product produced under religious exemption) that must be evaluated by LPDS prior to entering commerce. Included in that group of labels are those labels that have a special statement or claim that were previously approved by LPDS. Thus, once a label is approved there are several changes that can be made to the label that do not impact the previously approved claims. These revisions do not impact the previously approved special statement or claim. In addition, for the additional changes to be generically approved, there cannot be any formulation changes or addition of ingredients that were not part of the previously approved label. For more in-depth explanation see discussion on page 9. Examples of the types of label changes permitted are: \u2022 Additional cooking instructions, e.g., the label originally includes cooking instructions for a conventional oven but now the establishment is adding instructions for a microwave. \u2022 Addition of a bar code \u2022 Addition of a brand name or changes to a brand name that do not include a new claim \u2022 Addition of defined nutrition claim \u2022 Addition of Julian date \u2022 Adding new establishments for certification claims that cover multiple establishments \u2022 Addition of a flag that would have to be associated with \u201cmade in USA,\u201d or \u201cproduct of USA\u201d. However, this change must follow the requirements of 9 CFR 317.8 (b) (2). \u2022 Addition of a flag, map, or geographic emblem without including emblem \u201cbrand 21","made in\u201d \u2022 Addition of e-mail address or website information \u2022 Addition of a logo or changes to a logo that does not include a new claim\* \u2022 Addition of a \u201cnon-GMO or \u201cnon-GE\u201d claim to a certified organic label. For more information see Labeling Guideline on Statements that Bioengineered or Genetically Modified Ingredients or Animal Feed Were Not Used in Meat, Poultry or Egg Products. \u2022 Addition of a nutrition facts panel \u2022 Addition of a scan code app or QR (quick response) code \u2022 Addition of geographic style to product names, e.g., Tuscan Style to a previously approved Italian Sausage label. When not an established style in the regulations or Food Standards and Labeling Policy Book, the third-party authority documentation must be included as part of the labeling record. \u2022 Addition of a universal product code (UPC code) \u2022 Additional meat or poultry cut not on the previous list of cuts approved except for organic claims \u2022 Addition of trademark that does not impact previously approved special statement or claim and does not add a new special statement or claim\* \u2022 Changes to the ad copy that does not include an additional claim that was not present on the previously approved label and does not conflict with the current claims on the label \u2022 Changing an approved claim to a synonymous claim (e.g., changing from \u201cno antibiotics used\u201d to \u201craised without antibiotics\u201d) \u2022 Changes to comply with Descriptive Designation for Raw Meat and Poultry Products Containing Added Solutions (9 CFR 317.2(e)(2) and 9 CFR 381.117(h)) \u2022 Changes to comply with Descriptive Designation for Needle-or Blade-tenderized Beef Products(9 CFR 317.2(e)(3)) \u2022 Changes to the cooking instructions provided it still complies with the requirements of

the corresponding HACCP category \u2022 Changes to the descriptive name \u2022 Changes to the design of the label including layout. The establishment has the responsibility to ensure that all mandatory features are still in the required location. \u2022 Changes to the design of the label including the layout to labels for export with deviations from domestic requirements. The establishment has the responsibility to ensure that all mandatory features are still in the required location and no new label deviations were created. \u2022 Changes to an e-mail address or website that was on previously approved label \u2022 Changes to the establishment number or legend except for organic product. (Changes to the establishment number for organic product must be evaluated by LPDS.) \u2022 Changes to the form of the product (e.g., changing from link sausage to bulk sausage or changing from sausage patties to sausage links)\* \u2022 Changes to the HACCP category (e.g., change from raw product ground to fully cooked not shelf stable) \u2022 Changes to the handling statement (e.g., keep refrigerated) 22", "\u2022 Changes to the label for compliance with the added solutions regulations (9 CFR 317.2 (e) and 9 CFR 381.117). \u2022 Changes to names of ingredients in the ingredients statement provided the addition complies with FDA or FSIS labeling policies \u2022 Changes to the net weight, including the addition of net weight labels (e.g., a label was approved for 1 pound (lb.) and the new label is for 2 pounds (lbs.) \u2022 Changes to the order of predominance or product formula without the addition of new ingredients \u2022 Changes to the packaging (e.g., going from plastic container to plastic bag) \u2022 Changes to the placement or location of the legend \u2022 Changes to the product name (e.g., changing the product name from sausage to Italian sausage provided it meets the regulation and/or standards) \u2022 Changes to the signature line (e.g., manufactured for or distributed by) \u2022 Changes to values in the nutrition facts panel \u2022 Changing from \u201cGE to \u201cGMO\u201d on certified organic or other third-party certified labels. For more information see Labeling Guideline on Statements that Bioengineered or Genetically Modified Ingredients or Animal Feed Were Not Used in Meat, Poultry or Egg Products \u2022 Removal of ingredients in product without the addition of new ingredients \u2022 Removal of nutrition front of pack icon. The addition of an icon that was not previously evaluated by LPDS would need to be submitted for approval. \u2022 Removal of previously approved claim. Appendix 4: Changes to labels with special statements and claims that require LPDS review 9 CFR 412.1 states that certain changes to labels are not permitted to be made generically. The labels must be submitted to LPDS for approval. For more in-depth explanation see discussion on page 9. Examples on the types of label changes that cannot be made generically include: \u2022 Addition of additional nutrients to the labels with nutrition front of pack (FOP) statement \u2022 Addition of an animal-raising claim \u2022 Addition of ingredients to labels with special statement and claims such as \u201cNatural,\u201d \u201cOrganic,\u201d and \u201cCertified Gluten Free\u201d \u2022 Change to the establishment number on labels with an organic claim \u2022 Change to the ingredients without changing the label. That would require a temporary approval from LPDS \u2022 Changing the organic certifier on an approved label 23", "Appendix 5: Blanket Label Approvals (Product Line or Multiple Products with Identical Claims) A Blanket Approval refers to an approval that would cover multiple products or product lines that is submitted to LPDS for approval because it falls under one or more of the four categories of labels described in 9 CFR 412.1. For more in-depth explanation see discussion on page 10. Examples of labels that can be approved as a blanket approval: \u2022 Addition of

animal-production claim to line that also bears an ingredient-related claim \u2022 Addition of FOP statements to multiple products in the same product line or company \u2022 Addition of a new supplier for an approved animal- production claim \u2022 AMS processing extra regulatory marking or verification programs\* \u2022 Changing the organic certifier on an approved label \u2022 Changing the source of meat from a previously approved label when the claims and ingredients have not changed from the prior approval \u2022 High pressure processed at establishment ABC \u2022 Religious exempt products\* \u2022 USDA Contract Compliance (AMS program)\* \u2022 USDA Food Shield (AMS program)\* \u2022 USDA Further Processed Certification Program (AMS Program)\* Appendix 6: Special Statements and Claims Generically Approved After the First Approval from LPDS There are certain types of special statements and claims for which LPDS only needs to see one label to ensure compliance with the regulations and after that initial approval, the label can be generically approved for additional products. This is provided that any future labels follow all FSIS rules, policies, and regulations. The establishment would also have to include a copy of the initial approval in their labeling record to provide assurance that the special statement or claim did initially receive approval from LPDS. If the special statement or claim has changed at all from the initial LPDS approval, the new label must be submitted to LPDS for evaluation. For more in-depth explanation see discussion on page 11. A bold red asterisk (\*) marks new or updated entries to the appendix. Items previously on the list not marked by a bold red asterisk (\*) may have been rearranged for ease of readability. Examples of labels that can be generically approved after initial LPDS approval: \u2022 AMS processing extra regulatory marking or verification programs\* 24", "\u2022 Nutrition FOP\u2014provided the format, location and nutrients remain identical to the initial approval. If the establishment changes the format, location, or nutrients, then the new label must be evaluated by LPDS \u2022 Certified Halal/\u2022 Certified Zabihah Halal- must have documentation in the labeling record current within the last year to support the use of the claim \u2022 Certified Kosher- must have documentation in the labeling record current within the last year to support the use of the claim \u2022 Certified Women\u2019s Business Enterprise \u2022 Employee Owned Certified \u2022 FDA nutrition facts panel- one approval from LPDS per format (e.g., full format, simplified, linear, tabular, dual column, or aggregate format) \u2022 For cooking only at establishment xyz- must have documentation in the labeling record to support that the product is being sent to another establishment for cooking \u2022 High pressure processed at establishment ABC \u2022 Sustainable Forestry Initiative Certified Sourcing \u2022 USDA Contract Compliance (AMS program)\* \u2022 USDA Food Shield (AMS program)\* \u2022 USDA Further Processed Certification Program (AMS Program)\* Appendix 7: Negative Claims Negative claims are claims that state a product does not contain a certain ingredient . Negative claims can be generically approved per 9 CFR 412.2 (b). Examples of negative claims include gluten free, no artificial colors, no artificial flavors, no artificial preservatives, no MSG, no MSG added, no nitrites and nitrates, no nitrites and nitrates added and no preservatives. \u2022 Gluten Free is a negative claim that highlights the absence of certain gluten-containing ingredients in the ingredients statement. FSIS does not define gluten free in its regulations but applies FDA\u2019s requirements for the voluntary use of the claim in 21 CFR 101.91. A claim of \u201cgf\u201d is generically approved unless it is a certified claim, e.g., \u201cCertified Gluten Free by (XYZ entity).\u201d Certified gluten-free claims need to be submitted to LPDS for approval with support for the claim. See the sample

label below for a gluten-free label claim that can be generically approved. 25", "Made with beef, pork and chicken Ingredient": Beef, pork, chicken, salt, spices, flavors, sodium nitrate, sodium phosphate, sea salt. NET WT. 7 oz (198g) Gluten Free \u2022 No Artificial Colors is a negative claim that follows the entry in the Food Standards and Labeling Policy Book that the product doesn't contain any artificial colors as defined therein: Labels of products that are artificially colored either by artificial colors or natural colors must bear a statement to indicate the presence of the coloring, for example, \u201cartificially colored\u201d or \u201ccolored with annatto.\u201d Products whose true color is disguised by packing media, for example, colored pickling solutions, must also have labels that include a statement that indicates the presence of the color. The statement must appear in a prominent and conspicuous manner contiguous to the product name. When a component within a product is artificially colored, for example, breading, sauce, and sausage, a qualifying statement is not necessary. However, in all cases, the presence of the coloring must appear in the ingredients statement. Common artificial colors are FD&C Yellow No. 5 or Yellow No. 5, Red Dye No. 40, FD&C Red No. 3, FD&C Green No. 3, and FD&C Blue No. 2. 21 CFR Part 73 lists color additives that are exempt from certification. Colors that are exempt from certification are not required to be declared by common or usual name on labels and may be declared as \u201ccolorings\u201d or \u201ccolor added.\u201d Examples of exempt colors include Annatto extract, Caramel, and Paprika oleoresin. In comparison, certified colors are listed in 21 CFR Part 74 and are required to be declared by common or usual name, e.g., FD&C Blue No. 1, FD&C Blue No 2, FD&C Green No. 3, FD&C Red No. 3, FD&C Red No. 40, FD&C Yellow No. 5, FD&C Yellow No. 6, Orange B, Citrus Red No. 2. \u2022 No Artificial Flavors is a negative claim that describes a product that contains no ingredients labeled as artificial flavors (e.g., Artificial Maple Flavor). Acceptable ingredients can include MSG, smoke flavor, flavors, natural flavors, disodium 26", "Skinless Chicken Breast No Artificial Colors or Flavors KEEP REFRIGERATED NET WT. 48 OZ (3 LB) Safe Handling Instructions This product was prepared from inspected and passed meat and/or poultry. Some products may contain bacteria that could cause illness if the product is mishandled or cooked improperly. For your protection, follow these safe handling instructions. Keep refrigerated or frozen. Thaw in refrigerator or microwave. Keep raw meat and poultry separate from other foods. Wash hands after touching raw meat or poultry. Cook thoroughly. ~ Keep hot foods hot. Refrigerate leftovers immediately or discard. Distributed by 1MB Ranch, Inc. 1234 Special Rd., Elsewhere, VA 54321 inosinate, disodium guanylate, hydrolyzed vegetable proteins, and yeast extracts. See the sample label below for a no artificial colors or flavors label that can be generically approved. \u2022 No artificial preservatives mean the product would not contain any source of artificial preservative. LPDS has allowed the claim of no artificial preservatives under the following conditions so the consumer is not misled about whether the products are preserved or not. The labeling claim would consist of: 1. A statement \u201cSee back panel for ingredients used to preserve quality\u201d would appear on the front panel in immediate proximity to the \u201cNo Artificial Preservatives\u201d claim. This will provide consumers with details about the claim-namely, the fact that the product has added ingredients that will help preserve product quality. 2. Each ingredient added to preserve the product would be declared with an asterisk in the ingredient line. The asterisk would lead to the following explanatory statement below the ingredient line: \u201cIngredient to preserve quality\u201d or perhaps a shortened

form like \u201cto preserve quality.\u201d See sample label below for no artificial preservatives claim that can be generically approved. 27", "FULLY COOKED No Artificial Preservatives See back panel for ingredients used to preserve quality Chicken Nuggets BREADED STAR SHAPED CHICKEN BREAST WITH RIB MEAT KEEP FROZEN NET WT. 5 LBS (2.26kg) Pepperoni Ingredients: Beef, pork, chicken, salt, spices, flavors, sodium phosphate, sea salt. NET WT. 7 oz (198g) Nutrition Facts About 25 servings per container Serving size 5 pieces (88g) Amount per serving 230 Calories %Daily Value\u2022 Total Fat 13g 20% Saturated Fat 3g 15% Trans Fat 0g Cholesterol 140mg 13% Sodium 480mg 20% Total Carbohydrate 14g 5% Dietary Fiber 3g 16% Total Sugars 0g Includes 0g Added Sugars 0% Protein 12g 24% Vitamin D 0mcg 0% Calcium 100mg 0% Iron 0.5mg 4% Potassium 0mg 0% The % Daily Value (DV) tells You how much of a nutrient is in a serving based on a 2,000 calorie diet. A day's calorie needs may be higher or lower depending on your age, sex, weight, and activity level.

INGREDIENTS: Chicken breast with rib meat, water, whole wheat flour, contains 2% or less of the following: dried garlic, corn flour, salt, spices, natural flavoring, lemon juice.\u2022

CONTAINS: Wheat. \u2022 To preserve quality Breading set in vegetable oil. No MSG \u2022 No MSG is a negative claim that means the product does not contain any sources of MSG. Common sources of MSG include any ingredient that is hydrolyzed or autolyzed such as autolyzed yeast extract. Other common sources of MSG are Worcestershire sauce and soy sauce. For a label that claims No MSG and does have a natural source of MSG, the claim would need to be changed to No MSG added with a disclaimer statement (see the next section for additional information). See sample label below for No MSG claims that can be generically approved.

28", "Made with beef, pork and chicken Ingredients: Beef, pork, chicken, salt, spices, flavors, sodium nitrate, sodium phosphate, sea salt, autolyzed yeast extract. No MSG Added\* NET WT. 7 oz (198g) \*Except for that naturally occurring in autolyzed yeast extract. \u2022 No MSG Added is a negative claim that means the product does not have any sources of MSG added but it does contain naturally occurring sources of MSG such as soy sauce or Worcestershire sauce. Other common ingredients include any ingredient that is hydrolyzed or autolyzed such as autolyzed yeast extract. For labels with this claim, it would need to state No MSG Added\* and then have a corresponding asterisk on the same panel with the \*except for that naturally occurring and identify the ingredients in the product that are the naturally occurring sources of MSG, e.g., \u201cNo MSG Added\* \*except for that naturally occurring in autolyzed yeast extract and Worcestershire sauce.\u201d The disclaimer statement must be on the same panel as the claim. See sample label below for no MSG added claim that can be generically approved.

\u2022 No Nitrites and Nitrates is a negative claim that means that the product would have no natural sources of nitrites, nitrates, or nitrites and nitrates (e.g., sea salt, cultured celery powder, celery powder, cultured celery juice or celery juice). Products labeled as uncured would need to follow the 9 CFR 317.17 requirements. See sample label for no nitrites and nitrates claim that can be generically approved.: 29", "Andouille Sausage Ingredients: Pork, beef, salt, sugar, garlic, spices, flavors. Keep Refrigerated NET WT. 7 oz (198g) \u2022 No Nitrites and Nitrates Added is a negative claim that means that the product would have natural sources of nitrites, nitrates, or nitrites and nitrates (e.g., sea salt, cultured celery powder, celery powder, cultured celery juice or celery juice). For products with this claim, sea salt and salt cannot be combined into one ingredient, those ingredients must be declared separately. For products that declare those natural sources of cure, the label would need to have a disclaimer statement.

\u201cNo Nitrites or No Nitrates Added\* \*except for that naturally occurring in sea salt and celery powder\u201d on the same panel as the claim For the ingredients cultured celery powder and cultured celery juice, they must be sublisted in the ingredients statement (e.g., cultured celery powder (celery powder, sea salt, silicon dioxide)). The disclaimer statement must be on the same panel as the claim. Products labeled as uncured would need to follow the 9 CFR 317.17 requirements. See sample label for no nitrites and nitrates added claim that can be generically approved. 30", "Sausage No nitrates or nitrites added\u2022 Ingredients: Pork, salt, sugar, garlic, spices, flavors, sodium phosphate, sea salt, celery powder. Keep Refrigerated NET WT. 7 oz (198g) \u2022 Except for those naturally occurring in sea salt and celery powder. \u2022 No preservatives is a negative claim that means the product would not contain any source of preservatives in the product. Per 21 CFR 101.22 (a) (5) \u201cChemical Preservatives\u201d means any chemical that, when added to food, tends to prevent or retard deterioration thereof, but does not include common salt, sugars, vinegars, spices, or oils extracted from spices, substances added to food by direct exposure thereof to wood smoke, or chemicals applied for their insecticidal or herbicidal properties. Some common chemical preservatives include BHA, BHT, calcium propionate, citric acid, natamycin and sodium propionate. For more information about chemical preservatives, please see 9 CFR 424.21 and FSIS Directive 7120.1- Safe and Suitable Ingredients Used in the Production of Meat, Poultry and Egg Products. See sample label below for no preservative label claims that can be generically approved. 31", "Skinless Chick.en Breast No preservatives KEEP REFRIGERATED NET WT. 48 OZ (3 LB) Ingredients: Chicken, salt, spices. Safe Handling Instructions This product was prepared from inspected and passed meat and/\u00b3 or poultry. Some food products may contain bacteria that coukt cause illness if the product is mishandled or cooked improperly. fol' your protection.follow these safe handling instructions. Distributed by 1MB Ranch, Inc. 1234 Special Rd., Elsewhere, VA 54321 Appendix 8: Export Labels with deviations from domestic requirements and Geographic Claims on Labels Export Labels that Deviate from Domestic Requirements: A labeling deviation is a feature on labeling that is not permitted on labeling domestically but is required or permitted by the importing country. FSIS regulations provide for deviations from domestic labeling requirements for products for export with deviations from domestic requirements under 9 CFR 317.7 and 9 CFR 381.128. Export labels that deviate from U.S. domestic requirements are approved generically provided the labeling deviations comply with the importing country\u2019s labeling requirements. Documentation supporting the acceptability of the deviation should be kept in the establishment\u2019s labeling records under 9 CFR 320.1(b)(11) and 381.175(b)(6). FSIS maintains an Export Library that lists requirements for exported products that foreign authorities have officially communicated to FSIS, including labeling requirements. At times, foreign country labeling requirements conflict with domestic requirements. FSIS regulations (9 CFR 317.7 and 9 CFR 381.128) permit export product labels to deviate from FSIS\u2019 domestic labeling requirements to comply with foreign country requirements or to be marketed more easily in a foreign country. Although there is no specific equivalent regulation for egg products, FSIS follows the same policy because such products, intended exclusively for export, must comply with foreign countries\u2019 requirements and are therefore not

considered misbranded. FSIS IPP verify whether product for export meets requirements listed in the Export Library, including labeling, when certifying products for export. 32", "The FSIS Export Library is a resource published by the agency for information on various countries importing requirements. In addition to the information in the Export Library, types of documentation typically used to support labeling deviations include a letter from the importer on its official letterhead, a letter from the government of the importing country, and excerpts from the importing country's regulations or laws, provided the source of the information can be verified by IPP e.g., a link to a government site listing official regulations. The information in the label record helps verify that the label complies with the importing country's requirements. Geographic Landmark Claims on Labels: \u201cGeographic landmarks\u201d are claims displayed on a product label, such as a foreign country's flag, monument, or map. For example, the following claims displayed on a product label no longer require LPDS review prior to entering commerce:a Polish flag depicted on a Polish sausage product label, or an outline of the State of Nevada depicted on a product label for beef produced in Nevada. There are several types of geographic landmark claims, including labels that comply with 9 CFR 317.8(b)(1) or 9 CFR 381.129(b), other options for geographic naming, state endorsement programs that have a geographic emblematic design, state endorsement programs that do not have a geographic emblematic design, and geographic style documentation by third-party authority. Labels that comply with 9 CFR 317.8 (b) (1) or 9 CFR 381.129 (b) (2) requirements: For labels that comply with 9 CFR 317.8 (b) (1) or 9 CFR 381.129 (b) (2), the product would need to be labeled as e.g., \u201cTuscan Brand Made in USA\u201d or follow one of the established styles in the Food Standards and Labeling Policy Book (e.g., \u201cItalian Style\u201d). Other options for geographic naming to comply with 9 CFR 317.8 (b) (1) or 9 CFR 381.129 (b) (2) include e.g., \u201cTuscan Inspired,\u201d \u201cTuscan Recipe Chicken,\u201d or \u201cChicken Tuscan.\u201d For a list of the established styles in the Food Standards and Labeling Policy Book, see the end of this appendix, if the style in question is not in this list, the label would need to comply with the requirements in 9 CFR 317.8 (b) (1), 9 CFR 381.129 (b) (2) or follow the third-party authority documentation requirement State endorsement programs that have a geographic emblematic design (e.g., Wisconsin Cheese with a map of Wisconsin or use of flag): State endorsement programs that have a geographic emblematic design (e.g., Go Texan with the map of Texas or Nevada Made with the map of Nevada) and a geographic logo, map or flag are generically approved per 9 CFR 412.2 (b). The label must comply with 9 CFR 317.8 (b) (1), 9 CFR 381.129 (b) (2) or an established style in the Food Standards and Labeling Policy Book. In addition, there must be support in the labeling record for the claim. The support can be a certificate from the agency running the certification program or a letter stating the label complies with the requirements. The supporting documentation needs to be updated yearly. 33", "State Endorsement Programs that do not have a geographic emblematic design: For the state endorsement programs that do not have a geographic emblematic design (e.g., \u201cPride of New York,\u201d \u201cKentucky Proud\u201d), there needs to be support in the labeling record for the claim. The support can be a certificate from the agency running the certification program or a letter stating the label complies with the requirements. The supporting documentation needs to be updated yearly. Geographic Style Documentation by Third-Party Authority: New geographic styles, not listed in the Food Standards or Labeling Policy Book, for example, \u201cLaos Style,\u201d must be supported by a third-party authority. The

third-party authority could be a chef or other culinary authority providing a definition for the style and stating how the product meets that definition. The geographic style documentation by a third-party authority must:

- \u2022 Indicate the type of product as identified with and peculiar to the area represented by the geographical term.
- \u2022 Indicate the characteristics of the X style in a manner that is quick and easy to understand. It may be a method of preparation and/or certain ingredients that are used.
- \u2022 Have characteristics that are unique to the geographical style for which the documentation is being provided; and
- \u2022 Provide the credentials of the person who is claiming to be the third-party authority. Further, unless the new style is documented in the Food Standards and Labeling Policy Book, the company needs to include supporting information in every labeling record that is generically approved and with every label that is submitted for approval.

Documentation requirements for Geographic Landmark Claims: The documentation for a geographic claim on a label must be updated once a year and be current for that year. The documentation to support the claim for a state endorsement program and state endorsement program with geographic emblematic design can be a certificate from a state agency. For the third-party authority, you need to have the supporting documentation and/or certificate updated once a year from the third-party authority to support the claim. Styles defined in the Food Standards and Labeling Policy Book

- \u2022 Asian Style
- \u2022 Country Style
- \u2022 Buffalo Style
- \u2022 Cajun Style/Cajun Recipe
- \u2022 Cantonese Style Spices
- \u2022 Creole Style
- \u2022 Italian Style (please note- Italian Style sausage must meet 9 CFR 319.145) 34",
- \u2022 Jamaican Style
- \u2022 Jerk or Jerk Style
- \u2022 Hawaiian Style
- \u2022 Mediterranean Style
- \u2022 Mexican Style
- \u2022 Nacho Style, Nacho Flavor and Similar Terms
- \u2022 New Orleans Style
- \u2022 Oriental Style
- \u2022 Santa Fe Style
- \u2022 Southwestern Style
- \u2022 Szechwan Style
- \u2022 Thai Style

Appendix 9: Additional Information for Label Approval This section provides additional information about the two other categories of labels that LPDS must evaluate. Also, the following provides some general information about label requirements. Labels for religious exempt products (9 CFR 412.1 (c)(1)): Poultry slaughtered under Buddhist, Confucian, Halal, or Kosher religious exemptions may not bear the mark of inspection. Because of this, the labels deviate from labeling requirements and must be approved by LPDS. For more information see Religious Exemption for the Slaughter and Processing of Poultry. Labels for temporary approval (9 CFR 412.1 (c)(4)): A temporary label approval may be granted for labels with a regulatory deviation that does not pose any potential health, safety, or dietary problems to the consumer. Temporary approvals will be granted for up to 180 days, and establishments can apply for one extension of up to an additional 180 days. Label transfers are a special type of temporary approval which is granted for 60 days with one additional extension. Temporary label approval is granted on a case-by-case basis. Example: A supplier changes ingredients and fails to inform the establishment, and the establishment needs to make a minor correction to the ingredients statement. The establishment can apply for a temporary approval to use the existing label, even though it does not have the correct ingredients statement. Only LPDS can grant temporary approvals for labels with deficiencies. The submitter must address the four conditions for temporary approval listed in 9 CFR 412.1(f) and explain how they meet each condition. As part of their label application, they must also explain exactly what is wrong with their label. Example: A change in the ingredients statement from what was approved in the past. The submitter would submit both ingredients statements and highlight the differences between them.

FSIS Verification Activities at Establishments

35","FSIS IPP perform routine and directed General Labeling Tasks as assigned by the Public Health Inspection System as part of their regular label verification activities under FSIS Directive 7221.1, Prior Label Approval. FSIS IPP verify that final labels applied to final product follow applicable regulations by evaluating information in the establishment\u2019s labeling record and the label that is applied to the product (e.g., to verify that the ingredients statement on the label matches the product formula). Neither establishments, LPDS, nor FSIS inspectors generically approve labels. Rather, such labels are approved by the regulations provided they follow applicable requirements in 9 CFR 412.2 (b). For additional information, see FSIS Directive 7221.1, Prior Labeling Approval. Labeling and Establishment Responsibilities concerning Label Approval Establishments are required to keep records of all labeling, both generically approved, and sketch approved by LPDS, along with the product formulation and processing procedures, as prescribed in 9 CFR 320.1(b)(11), 9 CFR 381.175(b)(6), and 9 CFR 412.1. For labels that are sketch modified by LPDS, the establishment is responsible for making the changes on the label as noted by LPDS, prior to the final generic label approval and printing. For establishments that are making changes to labels previously approved by LPDS, they must update the labeling records and label to reflect the changes made. If the label has claims that are impacted by the ingredients, then the label would need to be resubmitted to LPDS for approval prior to use. 9 CFR 412.1(a) added the requirement that any additional documentation needed to support that the labels are consistent with the Federal meat and poultry regulations on labeling also be kept. For example, in a situation where an establishment is making an undefined geographic claim on a label (\u201cTuscan style\u201d), documentation should be included to support that the style meets 9 CFR 317.8 (b). Companies must provide labeling records to FSIS personnel upon request as described in 9 CFR 412.1(a). For additional information see: Labeling and Establishment Responsibilities. 36","SMALL PLANT HELP DESK i'h!JHIW.:~ sm lt1nil'frH'7:!!&J.II fil~ -L 12-17~Z.OJ 0 ;\~-fm~1MLUI La. r,um lup il'h.'r'b.luu U~iu .I 11tnil11\u2022 nil \u2022u..d , .. ,hnlh l~,c,i,r.
